
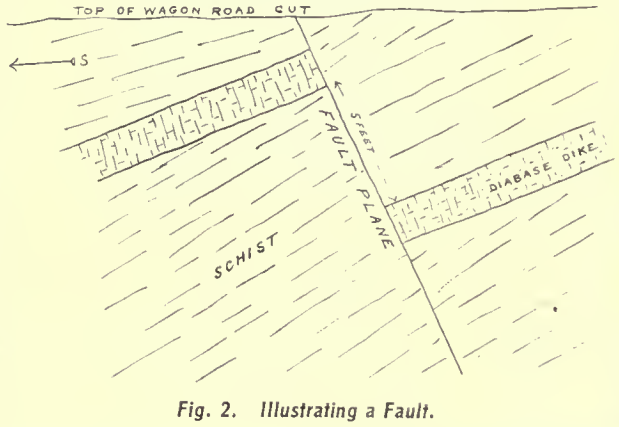

Fig. 2. Illustrating a Fault.

The country between the mine and the railway, and as far in any direction as the eye can reach, is of typical desert character—generally flat, with occasional low jagged hills. The most prominent topographic feature is Vulture Peak, several miles to the east, a mass of volcanic rock.

What little can be learned concerning the history of the

*The paper mentioned appeared in the MINING AND SCIENTIFIC PRESS of October 20, 1906.

mine is of sinister character. Discovered by Americans in 1863, the account of its riches spread through the Southwest. Some of the pioneers of quartz-mining faced the difficult problems connected with its operation. Swarms of nondescript laborers, desperate and adventurous nomads of the West whose origin and careers are alike shrouded in oblivion, made for a time a settlement in that awful desert. For twenty years the Vulture vomited its golden stream. Dim rumors of pillage and of tragedy sift through the years. Popular account says that the Indians shot down men at the stamp batteries.

As nearly as can be learned, 700,000 tons of ore were mined and treated from the Vulture, from which an average of $10 per ton in gold was recovered. The ore was of variable tenor, rich pockets occurring in all parts of the workings, and the mine was finally abandoned not because the ore became too low-grade at the moderate depth attained, but for the reason that the orebody was completely lost. A six foot sample taken from a pillar, in 1906, at 300 ft. down in the west incline gave 0.9 oz. gold. The year 1873 seems to have marked the cessation of deep exploration, and from about this time until 1885 the large mill at the mine was run on the low-grade ore that had been left in the upper workings by the earlier operators. Since 1885 only small attempts have been made to operate the mine under lease, and the tailing at the mills has yielded a small return by cyanidation.

The country rock is sericite schist of probable Algonkian age. It is certainly pre-Cambrian. It forms a low ridge with east and west trend about one mile in length. It extends five miles east and five miles west, and distances of at least one mile to the north and to the south of the Vulture mine. The strike of the schist is north 75° west, dip 35° northeast. The main Vulture lode is a quartz vein six feet wide intercalated with the schist. Other smaller veins, also intercalated, and intermediate mineralized country rock, make a mass of lode-matter, which was worked as ore from 10 to 30 ft. in width. There is no reason to doubt that similar intercalated veins exist in the schist, buried beneath the desert alluvium both to the north and to the south.

The hand specimen of the schist taken from the hanging wall of the lode shows an intimate fine-grained mixture of sericite and chlorite, with numerous almost microscopic crystals of a dark silicate, which I take for garnet. There is also magnetite in considerable quantity. The white silvery mica is the predominating constituent. The character of the ore taken from the outcrop shown in the photograph, Fig. 1, is a dark fine-grained aggregate of quartz, penetrated with a net-work of secondary glassy quartz stringers. The dark primary quartz carries fine, almost microscopic, sulphides. Small vugs contain crystals of wulfenite. I understand that lead, molybdenum, vanadium, and copper in rare compounds and in a fine state of division have been recognized in the concentrate. A secondary silicification is very apparent, and seems to have affected alike the original vein-filling and the adjacent country-rock. The appearance of the ore suggests that secondary enrichment of the gold has occurred, but my inspection of the old workings, to the 350-ft. level on the incline, did not establish the fact that the lower limit of this enrichment had been reached.

The structural features of the deposit are interesting. The case of a well-defined lode of quartz intercalated in sedimentary schist lying in inclined position is to some extent similar to the occurrence of the Main Reef on the Rand. The geological conditions are complicated at the Vulture by faulting. Previous to the faulting, diabase dikes were intruded in the schist, parallel with it in strike but slightly less steep in dip. Cutting the schist, the dikes, and the Vulture vein are narrow fissures some of which are filled with quartz while others are unfilled. These strike north 50° east, and are either vertical or inclined steeply to the southeast. Reverse faulting has occurred along these fissures, the north portion of the vein and beds being in every case lifted up to the north, with a throw of moderate degree. The sketch, Fig. 2, shows an observed case, about 500 ft. southwest from the outcrop of the vein. There are many evidences of this faulting, and detailed study of the mine workings would probably establish the fact that the orebody has been successively lifted to the north. A series of such faults close together would result in a total throw of considerable magnitude. Rumor concerning the former work says that the orebody was lost in depth. If the ore deposit persists in depth, cross-cutting to the north would find it, as there can be no question that the vein itself continues downward. The deepest point now accessible is the so-called 400-ft. level of the west incline, below which water stands in the mine. Even at this level it is apparent that the main vein lies in the north or hanging wall of the incline.

In 'Mineral Resources West of the Rocky Mountains,' 1874, it is stated: "Up to the time that operations stopped on the Vulture (sinking operations on the east end, above referred to, about 1872) prospecting in the lower shaft was carried on with as much energy as circumstances would permit, and from the work done it is clear that the Vulture is a true fissure vein of large proportions. The depth attained on the mine is 312 ft. below the surface of the mesa, or fully 390 ft. below the croppings of the lode. At a depth of 232 ft. below the surface of the mesa the fissure was found to change from a dip of 45° north-northeast to an almost vertical position." * * * * "It may be here mentioned that the best body of ore which was taken from the mine was found just above where the fissure changed its dip." * * * * "After sinking 50 ft. behind the foot-wall, from the 232-ft. level the fissure was cross-cut and found to be 47 ft. in width and having on the hanging wall a seam of blue clay some 12 or 15 in. thick. Outside of this was the hanging-wall rock peculiar to the mine above, but the fissure throughout its width was found to be filled with a hard black rock full of iron pyrites, and some galena." * * * * "The shaft was then sunk 30 ft. farther, and a cross-cut was again made." * * * * "The vein-stuff had again changed somewhat, this time for the better; a little more quartz, from which some fine gold was taken, having made its appearance." "As soon as the vertical fissure was struck, water also began to make its appearance, and it increased steadily, though slowly." "This cap, to judge from developments made above, rises gradually toward the east, and dips westerly along the line of the fissure, with the same inclination that way as that which the pay-shoots of ore had above. They were all found to run diagonally west across the dip of the vein."

The above language, being interpreted, means that near the east end of the deposit, about 1,200 ft. east of the incline-shaft before referred to, exploration in depth got off the main vein, and followed instead one of the vertical veins of later age, which have been responsible for the faulting of the main orebody. It does not appear that any more work has been done at the east end since the cessation of that above described. There was no change of dip from "45 degrees" to vertical, but the vertical shaft encountered an entirely different vein, the main Vulture lode lying still farther to the north.

For a length of over 1,500 ft., a width varying from 10 to 30 ft. and to a depth on the dip of the vein of from 300 to 400 ft. the orebody was stoped out, large pillars being left for support. Since 1885, the date of the last extensive work, two enormous caves from surface have occurred,

so that the mine now has the appearance of a series of great open-cuts, their walls honeycombed with a network of lateral chambers. A sense of awe strikes the beholder who looks on this scene of utter desolation and decay.

The Algonkian schist occurs in patches far to the eastward and to the north. In the vicinity of Jerome, 100 miles to the northeast of the Vulture, similarly intercalated veins in schist pass upward, according to T. A. Jaggar and Charles Palache, into overlying horizontal Carboniferous rocks. The age of these veins is consequently post-Carboniferous. At the Congress mine, 35 miles to the north, an intercalated vein in schist has been worked for gold to the depth of 4,000 ft. on the incline. I cannot say whether it is conformable in dip and strike with the Vulture occurrence. I have examined a portion of the Pinal schist area in the Globe district, 150 miles to the east of the Vulture, and find a considerable similarity in appearance.

Sericite is abundant, although there is a greater amount of elongated quartz nodules. The Globe schist is called pre-Cambrian by F. L. Ransome. It contains visible flakes of copper pyrite, and certain belts of it are mined as copper ore. Assays of $3 in gold can be obtained in places, as at the Cole & Goodwin mine. It is probably safe to refer the first mineralization of the Vulture lode to Permian age while it is almost certain that a second series of nearly vertical veins cutting the schist was subsequently formed, and by the agency of their filling the older veins were enriched.

In general, attention should be called to the fact that the pre-Cambrian schist of Arizona has a wide distribution and contains notable orebodies. A geological map of Arizona showing this distribution may some day prove an important guide to the sensible prospector. We are indebted to Mr. Rex Beach for an Alaska "sour-dough's" rendition of the legend of the Golden Fleece, in which he asserts that the "Augernots" abandoned their search for gold when they found the "formation was like Texas, not right for mineral," so they went into the "sheep business." The prospector should realize that "mineral" will "live" in old formations as well as new, and that gold may be awaiting him encased in Algonkian schist as well as in "phonerlite" or in rhyolite.

SODIUM TRANSMISSION LINES.—The use of sodium for overhead transmission is attracting the attention of electricians. It is said to be cheap and a good conductor of electricity, but as its marked affinity with oxygen causes it to ignite when placed in contact with water, its employment in the form of a conductor would be limited, probably, to overhead transmission lines or feeders for railway work. The general process of constructing sodium conductors is to take standard wrought-iron pipes and heat them to a point well above the melting temperature of sodium. The sodium is then melted in special kettles and is run into the the pipes, solidifying when cool. There is said to be no marked depreciation of either the sodium or the pipe if the latter be properly protected by a coat of weather-proof paint. For the same conductivity the price of the complete sodium conductor is much below that of copper cables, being in small sizes not more than 50% and in large sizes not more than 20% of the cost of copper. For instance, a half-inch wrought-iron pipe filled with sodium has a capacity of 109 amperes, and costs about 3½c. per ft., against 8½c. for a copper line of the same capacity. A 6-in. sodium conductor would carry 8,130 amperes, the cost of the line being about $1.40 per linear foot, as compared with $6.30 per foot for copper. These figures were estimated on the basis of 7½c. per lb. for sodium and 16c. per lb. for copper.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

The locators of a mine, on the day of a location, posted notices thereof, set stakes at the northeast and southwest corners of the claim and remained thereon until twelve o'clock midnight of the same day and immediately left the claim and never did anything further in the way of taking possession thereof. Three months thereafter another person made a new location of such claim. Under these facts it was held that the first locators did not proceed far enough to acquire rights sufficient to make the claim abandoned property within the meaning of the statute, and that the re-location was sufficient, though the certificate did not state that the whole or any part of the new location was located on abandoned property, where it further appeared that the re-locators complied with the requirements of the statute by sinking a discovery shaft upon the lode.

Paragon Min. &c. Co. *v.* Stevens, Co. &c. Co., (Wash.) 87 Pac. 1,068.

Two persons owned an undivided half-interest in a mining claim. One of such owners continued a tunnel driven on the claim through such claim to another mine owned by him, and thereafter worked his mine and attempted to convey the output through such tunnel, basing such right on the fact of his joint ownership of such mine. In a controversy over such right it was held that the owner of an undivided interest in a mining claim had no right to use a tunnel driven on the claim to convey ore from an outside claim.

Laesch *v.* Morton, (Colo.) 87 Pac. 1,081.

Where a purchaser of coal refused to take the quantity specified in the contract, and where it appeared that a custom among coal dealers made it necessary that such a contract be made, and the mining company in reliance on such contract only contracted with others for the balance of its output, it was held that in an action for the breach of such contract, that the damages should be computed by deducting from the contract price of the undelivered coal the original cost of the coal and the expense of mining it.

Thistle Coal Co. *v.* Rex Coal &c. Min. Co., (Iowa) 109 N. W. 1,094.

It is said that the locator of a mine, without obtaining a patent, acquires the possessory title thereto against all the world, and as against the Government so long as he performs the annual amount of work required thereon; and he may transfer this possessory right or title to a purchaser, who may, as the apparent owner, hold it against unrecorded equitable claims, without notice. The purchaser of the legal title of a locator has a prior and superior equity over a claimant of a prior equitable interest only.

Reed *v.* Munn, 148 Fed. 731.

The United States statute requiring the notice of the location of a claim to contain a description by reference to some natural object or permanent monument as would identify the claim, was held to be sufficiently complied with under a system of locating placer mining claims upon a gulch or creek, and calling the first 'Discovery Claim,' and then numbering the others from this first claim up or down the gulch or stream, and giving to the side or bench claims the same number as those upon the creek, with the addition of a letter of the alphabet. And that a recorded notice of the location of a claim in such locality, describing it as "13 A. Below Discovery on Cleary Creek," was held sufficient.

Smith *v.* Cascaden, 148 Fed. 792.

A person residing in a tent on one of a number of adjoining mining claims owned by him, and who had commenced the sinking of a shaft thereon, was held to have sufficient possession to entitle him to maintain an action against an adverse claimant of the ground.

Lange *v.* Robinson, 148 Fed. 799.

Mining in South Africa.

Contributed to the MINING AND SCIENTIFIC PRESS
By J. B. PITCHFORD.

*South Africa extends from the Cape to the Zambesi river, about 1,700 miles, covering an area of 1,400,000 square miles. It includes Rhodesia, the Transvaal, Swaziland, Basutoland, Natal, Orange River Colony, Cape Colony, Zululand, and Beehuanaland. The native population including Portuguese Territory is about 5,000,000. The area of Rhodesia is 750,000 square miles. The Transvaal is 126,000 square miles in area (about four-fifths the area of California).

The most important gold discoveries have been made in the Transvaal where now one-third of the total gold output of the world is produced from a stretch of gold-bearing lodes 60 miles in length. The Transvaal was a bankrupt country in 1877, but it is now producing gold at the rate of $120,000,000 per annum.

The white population of the Transvaal is about 300,000; of these, 114,000 live in the vicinity of the mines. There are 100,000 natives and 53,000 Chinese employed on the mines of the Witwatersrand and there are about 50,000 natives employed in other occupations among the mining towns. The 114,000 white people of various occupations on the mining area of the Witwatersrand are supported by the mining industry and their numbers have increased proportionally as the mining industry has progressed. When the mines were first discovered only the high-grade ore was worked. At the present time the average value of the ore mined and treated is only $8.50 per ton. It requires economical mine management to produce $10,000,000 per month from ore going $8.50 per ton in a country where living expenses are twice as high as they are in the United States, and pay interest on capital invested. The skilled labor is performed by white men and the unskilled labor by negroes or Chinese under the direction of white men.

The white miners and mechanics (not including officials) are paid $4 to $5 per day and the colored labor costs from 75c. to 80c. per day including food. White contractors make from $150 to $500 per month on rock-drill work. Over fifty-five per cent of the mining costs is paid out for wages, and three-fifths of this amount is for white labor including staff officials and clerks. It will be seen that all white labor could not be used for mining eight-dollar ore so as to pay for supplies and interest on capital invested where the conditions are such that it takes four people to mine and extract the gold out of a ton of it, in a country where the cost of living is double what it is in the United States. A mine crushing 500 tons per day is sometimes capitalized at $2,500,000.

Working expenses vary from $5 to $8 per ton. The natives and Chinese are fairly good workers when properly managed. The principal work they do underground is single-hand drilling, shoveling and tramming, and assisting white rock-drill men and other miners. Some of them are proficient at single-hand drilling and they can put down a three-foot hole in quartzite in from two and a half to three and a half hours, and this is considered a shift's work and entitles them to a day's pay.

The gold mines of the Transvaal are situated in a district known as the Witwatersrand, with the town of Johannesburg, at an altitude of 5,500 ft., in the centre. Mining operations are carried on continuously along a distance of 60 miles. There are over 60 producing mines and some of these can pay 20 to 25% interest on their capitalization. The capital expenditure on some of them will average $24,000 per stamp in the mill. The equipment of a mine on a basis of 200 stamps costs from $10,000 to $15,000 per stamp and the balance of expenditure goes for development and in purchase of claims.

A quartz mining claim in the Transvaal is 150 ft. long on the strike of the lode and 400 ft. wide. The Government license fee is $1 per claim per month. In addition to this, the Government takes 10% of the net profit on the gold produced. The Boer Government used to take five per cent of the net profit. Under existing conditions in the Transvaal, it does not pay to organize and equip a mine having much less than 100 claims. The lodes can only be followed within perpendicular lines of the claim-boundaries and this arrangement saves many lawsuits. Overlapping claims are not recorded.

The talent of mining engineers from all parts of the world has been brought to bear at Johannesburg and no expense has been spared to obtain good organization and up-to-date equipment. Complete statistics are kept at all the mines on a basis of costs per ton mined and milled, and rigid comparisons are made between those mines working under similar conditions, so that each manager or superintendent is held accountable to his directors for any excess in his costs per ton over that of his neighbors.

Costs are subdivided as follows: Mining, Hoisting, Pumping, Transport, Sorting, Crushing, Milling, Cyaniding, Electric Power & Lighting, Maintenance, Development, and Office Expenses. The total cost per ton of ore mined ranges from below $5 to $8 at the present writing. Twelve years ago the total cost per ton averaged $2 more, and a still further reduction may be looked for if the people that read about the natives in missionary books six thousand miles away will allow the white people living in Africa, who understand natives and other local conditions, to manage their own affairs. At the present time one-third of the unskilled labor is Chinese, one-third negroes imported from Portuguese territory and one-third negroes accumulated from British colonies extending over a distance of 1,700 miles. All this unskilled labor has to be dealt with fairly and controlled properly in order to carry on a large industrial enterprise. The natives, as a rule, prefer to stay on their land, or work in stores or houses to working in the mines.

It is significant that, under the present working conditions, 55% of the working cost is paid out for labor and nearly three-fifths of this is for white labor. About 11% of the working cost goes for explosives and 8% for coal. The remaining 26% goes for stores and maintenance. The average gold output of the Transvaal mines for 1906 was ten million dollars per month and the average value of the ore treated was $8.50 per ton. Some of the richest mines, such as the Robinson, produce ore up to $15 per ton. Underground costs run from $2 to $3.50 per ton, depending on thickness of lode, angle of dip, depth of working, water, etc. The veins worked vary from one inch to 15 ft. in thickness. Milling the ore costs from 50c. to 75c. per ton. Cyanidation and slime-treatment cost from 50 to 75 cents per ton. Stoping is done on contract at prices varying from $10 to $16 per fathom.

Drifts and cross-cuts 5 by 7 ft., in quartzite, are driven by contractors at the rate of $7 to $8 per linear foot. Out of this they have to pay the company 75 cents per day for the natives they employ, 30 cents per lb. for the dynamite, $3.25 per box of candles, 10 cents per coil of fuse, 75 cents per box of caps, and 3 cents per point for each drill sharpened. It takes 3 to 5 lb. dynamite per ton of ore blasted in driving and cross-cutting. Ten to 18 lb. per foot is used for shaft-sinking and 1.5 to 2 lb. for the total tons of ore mined, the larger portion of the rock being quartzite. Each ton of ore mined requires the consumption of 300 lb. coal.

There are three parallel veins in the Witwatersrand,

*A lecture delivered to the mining students of the University of California by Mr. J. B. Pitchford, late manager of the Randfontein Deep mine, Johannesburg.

but the distances between them and their respective thickness vary in different parts of the district. This gold-bearing conglomerate is termed 'banket,' and consists of pebbles cemented together, Sometimes the pebbles are clear and vitreous and sometimes milky or black, and they are frequently surrounded by pyrite in the matrix. The veins vary in thickness from one inch to 15 ft. The specific gravity of 'banket' varies from 2.65 to 3; 11½ to 12 cu. ft. make a ton of ore in place. The latter figure is usually adopted for estimating tonnages in the mine. The workable tonnage in these mines has been doubled in the past ten years in consequence of the reduction of $2 per ton in working costs. The value of the ore that can be profitably mined under existing conditions varies from $6 to $20 per ton, and the average value of the ore milled in 1906 was $850 per ton.

The following example in ore-sorting will be suggestive: A mine contains 7,200,000 tons of ore that will yield $10 per ton. The capacity of the mill is 1,000 tons per day; the hoisting capacity is greater.

The cost of mining and surface expenses is	$6 per ton
" " " milling and cyaniding	1 " "
The net profit remaining will be	3 " "
7,200,000 tons at $3 gives a profit for 20 years' work of	21,600,000
The rate of profit per year	1,080,000
Now $1 per year invested at 5% compound interest for 20 years is	$33.066
Hence $1,080,000 profit per year at 5% interest for 20 years is	35,711,280

This being the total profit of operation at end of 20 years without sorting.

If now 15% of the ore, or 1,080,000 tons, that goes $1 per ton, is sorted out, there will remain 6,120,000 tons to be milled.

7,200,000 at $10	$72,000,000
1,080,000 " $1	1,080,000
6,120,000 at $11.588	70,920,000

Thus there will remain to be crushed 6,120,000 tons at $11.588 per ton.

All the 7,200,000 that is hoisted costs $6 per ton	$13,200,000
Sorting 7,200,000 tons at five cents	360,000
6,120,000 tons to be milled at $1	6,120,000
Total costs	$19,680,000
Product, 6,120,000 tons at $11.588	70,920,000
Net profit	$21,240,000

Or net profit equals $1,249,411 per year for 17 years.

Now $1 per year at 5% compound interest for 17 years equals $25.81. Hence profit of the $1,249,411 per year at 5% compound interest for 17 years $32,284,780

Now $1 at 5% compound interest for 3 years equals $1.1576. Hence at end of three years, $32,284,780 would amount to $37,372,861, or total profit at end of 20 years for sorting system.

Now	$37,372,861	profit at end of 20 years for sorting system,
Less	$35,711,280	" " " " " " non-sorting "
Equals	$1,661,681	which represents increased profit at end of 20 years for the sorting over the non-sorting system.

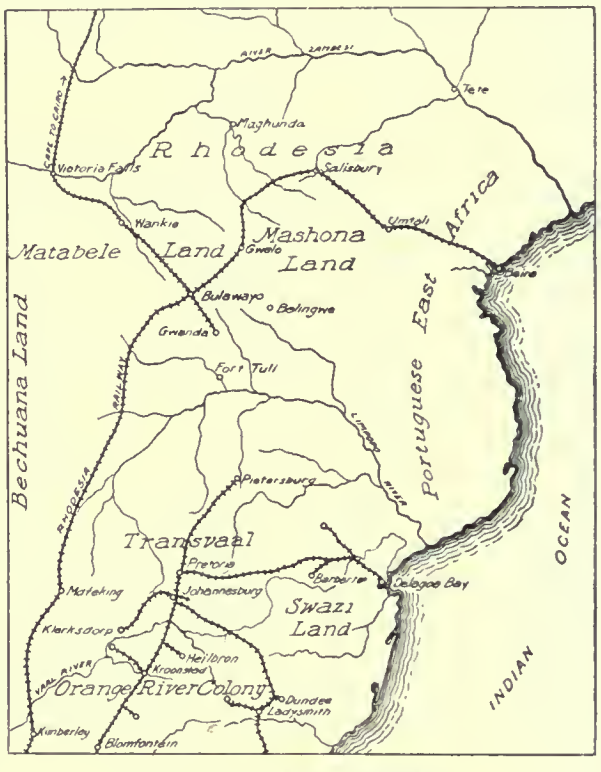
But as the mine would have been worked out in 17 years, the mine-plant could have been sold and realized on three years earlier or used for three years on other property.

These figures are based on sorting after the ore is brought to the surface. Ore sorted underground would save the cost of hoisting.

It is customary to sample the stopes from which the ore is being taken for the mill, in order to keep the grade even and the monthly output regular. The development drifts and winzes are sampled every five feet in short sections, across the stoping width of the lode. The results are recorded on the assay-plans in inches and pennyweights, equivalent to inch-dollars. By determining the assay-value and the width of the lode all around a block of ore, the tons and value per ton can be estimated for all the ore in reserve in the mine. Development work on three sides is sufficient to render an estimate safe, and some mines have as much as two years' development work done in advance of a 200-stamp mill crushing at the rate of six tons per stamp per day. Development work in drifts, winzes, and raises costs from 50 to 90 cents per ton for the ore blocked out. This is added to the mining and milling costs or is written off periodically.

The expenses of equipping one of these mines on a basis of a life of 15 or 20 years involve shaft-sinking at a cost of $100 to $150 per foot; winding engines; air-compressors and rock-drill plant; electrical power and lighting plant; pumping machinery, mills, cyanide works, furnace, and melting houses; buildings for natives and whites, stores and offices, water reservoirs and water-supply installations, and transportation facilities.

Some of the larger mine equipments have cost over $5,000,000. The enterprising people who have invested millions for the development of these mines deserve great credit for the sportsmanlike nerve they have shown in combating difficulties and in running risks for the purpose of building up a profitable industry, which furnishes a large lucrative market for manufacturers and gives employment to thousands of white people in numerous callings, besides promoting a wide distribution of wealth.



Map of the African Goldfields.

(TO BE CONTINUED.)

TEHAUNTEPEC RAILWAY.—The new railroad recently opened for traffic across the isthmus of Tehauntepec is expected to prove of great importance to the world's commerce. For the time being the new route will be directly available for the transportation of American domestic traffic only, the first steamship connections being those provided by the American-Hawaiian Steamship Company. Under a freight contract, which the steamship company signed in 1906, and particulars of of which were given by Special Agent Pepper a year ago, about 300,000 tons of sugar will be shipped annually from Honolulu via Tehauntepec to New York, Philadelphia, and New Orleans. The distance from New York to Honolulu via Tehauntepec is 5,699 nautical miles, while the distance via Panama is 6,688 miles.

THE forces that produce movements of the earth's surface are called 'diastrophic,' and are of two classes. The movements that involve broad, or continental, areas are termed 'epeirogenic,' while those which have to do with the uplift and crushing of belts of land, producing mountain ranges, are called 'orogenic.'

How the Miner's Dynamite is Made.—I.

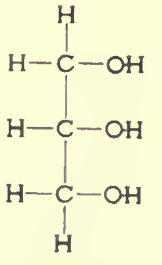
Written for the MINING AND SCIENTIFIC PRESS
By WHITMAN SYMMES.

Dynamite is a mixture of nitro-glycerine (which is a heavy oily liquid) and an absorbent, such as wood-pulp. The mixture is preferable to nitro-glycerine alone, because it can be handled as a solid instead of a liquid, and also because a much heavier shock is required to explode it, thus making it comparatively safe to move. The nitro-glycerine is commonly spoken of by men about the works as the 'oil,' and the absorbent material is called the 'dope.' The making of dynamite falls naturally into two parts: First, the manufacture of the nitro-glycerine; and secondly, the mixing of it with the dope and the packing of the dynamite meal thus made into sticks and cases. The making of the nitro-glycerine proceeds in three departments: First, the manufacture of nitric and sulphuric acids; second, the manufacture and separation of the nitro-glycerine; and third, the recovery of as much as possible of that portion of the acids that has not been consumed in making the nitro-glycerine, for use over again.

Explosives are made by obtaining oxygen in some concentrated form and mixing it with a combustible, so that the latter can be burned instantly, without the necessity of obtaining the oxygen for its combustion from a large quantity of air. The gases generated by the combustion and expanded by its heat, give the force to the explosion. Thus black powder is made by mixing charcoal and sulphur, which are combustibles, with nitre (potassium nitrate), which is 47.4% oxygen. In nitro-glycerine, the glycerine is the combustible and nitric acid (which is 71.2% oxygen) supplies the oxygen to burn the glycerine.

Glycerine is a combustible, just as wood and coal are. It is made from fat, which when treated with steam under pressure, separates into glycerine and stearic acid (from which candles are made). And it is also recovered by the Van Ruymbeke process from the waste liquors left after fat has been worked up into soap. The explosion of nitro-glycerine is much sharper than that of gunpowder, because the oxygen in it is mixed with the combustible in a much more intimate way. Gunpowder is merely a mechanical mixture in which the particles of combustible and the particles of the oxygen-carrier (nitre) are lying side by side. In nitro-glycerine, however, the oxygen-carrier does not exist as a separate particle, but has been injected into the molecule of the glycerine itself. In gunpowder the separate particles are, say, one thousandth of an inch in size, and therefore the elements must move on an average that far when they unite in combustion. But a molecule is supposed to be only a five billionth of an inch in size, and each molecule contains atoms of combustible material and atoms of oxygen. In fact, the atoms are so very close together that they are almost touching, and if we hit the nitro-glycerine a sharp blow we jar them so that the atoms of combustible and the atoms of oxygen are thrown far enough out of their places to come in contact with each other and an explosion takes place. If we jar all the molecules at the same time, then they all explode at the same time, and the explosion is terribly sharp. But if we mix the nitro-glycerine with some less active material and detonate it at one end, then it takes an appreciable amount of time for the jar to travel to the other end of the mixture and the explosion is not quite so sharp. Thus the explosion of dynamite containing 70% nitro-glycerine is much sharper than that containing 40%; and by using only 5% we make a variety known as 'low' powder, which has a lifting instead of a shattering effect, and it is largely used as a substitute for the common black powder. Many of the sporting and military powders contain high percentages of nitro-glycerine. Cordite, the English powder used for rifles and large guns, contains 58%, but the extreme heat of the explosion and the high velocity imparted, erode the bore of the gun to such an extent as to provoke criticism. The manufacture of dynamite is at present in a transient stage. Great advances have been made over the methods in use five years ago. The American hunger for improvements has been just as much in evidence in the powder business as in copper smelting or electric railroading. Experimenting has been incessant. In consequence, many changes and additions have been made at all the dynamite works.

It is impossible for anyone to understand the import of all that is being done in the business without knowing exactly what takes place in the nitrator when glycerine is converted into nitro-glycerine. A molecule of glycerine is composed of 3 atoms of carbon (C), 5 atoms of hydrogen (H) and 3 radicals of hydroxyl (OH). It is represented graphically in Fig. 1, in which each letter stands for an atom. A molecule of nitric acid (which is used to supply oxygen to the glycerine and thus make it



Glycerine

FIG. 5.

combustible) is composed of 1 atom of hydrogen (H), 1 atom of nitrogen (N) and 3 atoms of oxygen (O). It is represented graphically in Fig. 2. What happens to the glycerine when we inject the oxygen-carrier into it? First, the radical of a molecule of nitric acid pushes the hydroxyl of the glycerine molecule out of the combination, and we have glycerine mono-nitrate. At the same time the hydroxyl radical that is pushed out unites with the atom of hydrogen that was formerly combined with the nitric acid, forming HOH (or H_2O), which is just ordinary water. The mono-nitrate and the water are platted in Fig. 3, the radicals which have exchanged places being printed in blacker letters for the sake of accentuation.

Similarly by bringing another molecule of nitric acid to act upon this same molecule of glycerine (or glycerol) mono-nitrate, a second hydroxyl radical can be displaced, forming glycerine di-nitrate and a second molecule of water (Fig. 4). And by acting still more strongly with nitric acid upon the glycerine di-nitrate, we can displace the third radical of hydroxyl and we then obtain glycerine tri-nitrate (which is ordinary nitro-glycerine) and a third molecule of water (Fig. 5). In the dynamite works

the acids are not strong enough to convert all the glycerine into the tri-nitrate, and some of the glycerine never gets beyond the di-nitro stage. In a manner similar to the manufacture of nitro-glycerine we can inject our oxygen-carrier (nitric acid) into other combustible materials such as cotton, wood-pulp, starch, phenol (carbolic acid) and naphthalene; thereby forming gun-cotton (tri-nitro-cellulose), nitrated wood-pulp, tetra-nitro-starch, tri-nitro-phenol (picric acid), and di-nitro-naphthalene. These and many other nitro-compounds are explosives like nitro-glycerine, but they possess some quality which unfits them for miner's use, although employed in military and sporting powders.

Now look again at our map of a nitro-glycerine molecule (Fig. 5) and you will understand why nitro-glycerine can be exploded by a shock. On the left side are atoms of hydrogen and carbon, which are both inflammable. On the right side are nine atoms of oxygen, more than enough to burn up all the carbon and hydrogen atoms. Between the oxygen and the combustible atoms, preventing them from coming in contact, are three atoms of nitrogen (N). But if you jar the nitro-glycerine by a sharp blow, such as the stroke of a hammer or the explosion of a detonating cap, then the oxygen atoms get shaken out of that fine acrobatic balance they have been in, and coming in contact with the combustible atoms, the latter all burn up instantly. The hydrogen atoms combine with the oxygen atoms to form water (steam), H-O-H, the carbon is burned to carbon dioxide (carbonic acid gas) O-C-O, while the nitrogen is set free as hot nitrogen gas. The liberation of these three gases in the small space formerly occupied by them when they were nitro-glycerine, expanded still further as they are by the heat of the combustion (temperature 5,700° F.) gives the disrupting force of the explosion.

By adding up the weights of the atoms in the formula given above (Fig. 5) any chemist can figure the weights of the materials that take part in a perfect reaction. If there is a perfect nitration, 100 lb. glycerine will combine with 189 lb. (pure) nitric acid, and as a result of such a complete reaction there will be formed 246.9 lb. nitro-glycerine and 55 lb. water.

In practice, however, it has never been possible to obtain so much nitro-glycerine as that. The nitration of glycerine only takes place when we employ very strong nitric acid. You will note in Fig. 5 that every time we form a molecule of nitro-glycerine we form three molecules of water. This water dilutes the mixture so that the nitric acid is soon too weak to have any further action on what remains of the glycerine. If we use nitric acid alone (in any practical proportion) we get di-nitro-glycerine instead of the tri-nitrate. So, to take up the water that is being formed, and thus keep the nitric acid near to its original strength, a large amount of strong sulphuric acid is mixed with it. Sulphuric acid has a great affinity for water, while it is accommodating enough not to act on the glycerine or on the nitro-glycerine that is formed.

You are now in a position to understand the direction to which three-fourths of the efforts toward improvement in the nitro-glycerine business have been made. It has been an incessant struggle to obtain the strongest possible acids. The stronger the acids the larger the yield of nitro-glycerine, and therefore the cheaper the cost of production.

There are four companies manufacturing dynamite upon the Pacific Coast: The California Powder Works at Hercules, the Giant Powder Co. at Giant, the California Vigorit Powder Co. at Pt. Isabel, and the Judson Dynamite & Powder Co., also at Pt. Isabel. All are in Contra Costa county, California. The Giant Powder Co. also has works near Victoria, B. C., and the California Powder Co. has works for making black and smokeless powder near Santa Cruz, Cal. In 1903 the California, California Vigorit, and Judson companies were absorbed by the E. I. du Pont de Nemours Powder Co. (the powder trust), which took in every dynamite establishment in the United States except the Giant and Aetna. The Judson works used to be situated at Nobel, in Alameda county, but after the explosion there in the summer of 1905, the 'trust' consolidated the Judson with the Vigorit plant, which was only one mile away.

The manufacture of dynamite in California is a big business. During 1905, 31,090 tons of Chile saltpetre (sodium nitrate) were entered at the port of San Francisco, nearly all of which was used in the dynamite business. Thirty thousand tons would make nitric acid and dope for 22,900 tons of 40% dynamite or 1908 carloads of 24,000 lb. each. This means that the production of dynamite on the Pacific Coast during 1905 averaged not far from 3,800,000 lb. per month. Although, as a civil and mining engineer, I had seen dynamite used in pretty large quantities, yet as carload after carload used to go out from our own and the neighboring works, I never could cease wondering how the miners and contractors could really make use of it all. Between three and four million pounds of the yellow meal are made here every month, with grinding, and boiling, and choking fumes; all mixed, and sifted, and rammed into five or six million little packages by deft hands! Nearly three thousand 50-lb. cases start each day on their journey to strange places, and still the orders arrive as regularly as the daylight for more, more!

The Judson company buys its acids from the San Francisco Chemical Co. (now owned by the Mountain Copper Co.) which is near-by at Fleming's Point, West Berkeley. The Vigorit company obtains its sulphuric acid from the Stauffer Chemical Co.'s plant in the neigboring town of Stege, and makes its own nitric acid. Formerly it used to buy its nitric acid also, but the incessant struggle for stronger acid put too severe a strain upon the telephone wire and the Vigorit company erected its own nitric acid works, the chemical company gladly acquiescing. The California works make their own acids as did formerly the Giant; but the latter is now obtaining its acids from the Peyton Chemical Works, near Martinez.

Sulphuric acid is made by burning sulphur and blowing the sulphurous gases, together with air and steam, into one or more large leaden chambers, about 20 by 20 by 100 ft. in dimensions. A little nitric acid is also used and becomes decomposed into oxides of nitrogen. These take up oxygen from the air that is present and pass it on to the sulphurous acid gas, which thereby becomes oxidized to sulphuric acid. The oxides of nitrogen are unchanged in the process and are mostly recovered for use over again. The sulphur burned in the furnaces is in the form of iron pyrites, containing generally 46 to 50% sulphur, as it costs in that form only a fraction as much as imported Japanese sulphur, which was the material used ten years ago. Low-grade copper ore (1.5 to 3%) is generally used, and the copper is afterward extracted by leaching (as at the Stauffer Chemical Co.) or by smelting, as at the smelters of the Selby and Mountain Copper companies, and at the Peyton chemical works.

The sulphuric acid collects in the bottom of the lead chambers and is then of a strength known as 'chamber acid,' containing about 60% acid and 40% water (sp. gr. about 1.5 = 48° Beaumé). As sulphuric acid of a greater strength, when hot, will attack lead, the last two pans in which it is boiled are made of heavy cast iron. Diluted sulphuric acid will dissolve iron, but strong sulphuric attacks it only very slowly—the stronger the slower. The

acid thus made is shipped in iron tank-cars to the powder works. It has a strength of 93 to 94%. Five or six years ago some of the works used it directly for making their nitric acid and nitro-glycerine, but it gave too low a yield and there was "no money in the business."

All the dynamite works, whether they make their own sulphuric acid or not, have plants for concentrating the 'waste' sulphuric acid that has been used once in making nitro-glycerine. Such a plant is called a 'recovery' and is exactly similar to the one I have just described for boiling down the 'chamber acid.' When the Judson and Vigorit companies found that the chemical works would not supply them with acid strong enough for the dynamite business they resorted to the expedient of boiling the acid they received a second time in their 'recoveries.' At first they were able to increase the strength only about 2%, but in the last couple of years they have been able to do better than that. This second boiling of the acid (and the same thing applies, of course, to the recovery of the waste acid) is a mean business. Strong sulphuric acid decomposes at about its boiling point, so that in the finishing pans much of it is decomposed and driven off with the water. The last iron pan is covered over and the fumes are conveyed to large lead condensing pipes, cooled by water. The condensation of acid and water is run back in a stream into the lead pans, in order to save as much as possible. When the cover of an iron pan wears through, the building is filled with white acid fumes and the place looks like a London fog and breathes like a choice apartment in hades. Every few months one of the iron pans wears through and spills the acid into the red hot furnace, and there is so much acid in the air that the building and the furnaces do not last many years.

During the last three years a wonderful new method of making sulphuric acid has come into use and bids fair to solve some of the most difficult problems that the dynamite men have had to face. This is known as the 'contact' process, of which there are several patented varieties. It turns out the strongest sulphuric acid at one operation, without any boiling whatever. Sulphuric acid is a combination of water and a whitish gas, known as sulphur tri-oxide or sulphuric anhydride. By dissolving this gas in water in the right proportions, we can obtain an acid of 100% strength. Moreover, we can go farther and dissolve some more sulphur tri-oxide in the 100% acid and thus obtain what is known as fuming sulphuric acid. Sulphur tri-oxide and fuming sulphuric acid used to be made before the advent of the contact process by distilling ferrous sulphate, and they have been in use for over a century; but thus made they were never cheap enough for the powder manufacturers. Sulphur tri-oxide can also be made by passing the gas from burning sulphur mixed with air over platinum 'black' (precipitated platinum), and this reaction has been developed into the present 'contact' process.

The contact process was first worked on a commercial scale at the great Badische Anilin und Soda Fabrik at Ludwigshaven on the Rhine, where large quantities of fuming sulphuric acid were necessary in the manufacture of aniline colors. The first plant on the Pacific Coast for the manufacture of sulphuric acid by a contact process was erected by the Peytons, near Martinez, in 1900. The Peytons had formerly been connected with the management of the California Powder Co.'s plant at Santa Cruz. They had rights to the Grillo-Schroeder process, which was invented in Germany and controlled in the United States by the New Jersey Zinc Company.

After numerous delays they succeeded in manufacturing a splendid quality of strong sulphuric acid that brought joy to the hearts of the powder men. Unfortunately, however, it did not bring corresponding profit to the treasury of the Peyton Chemical Co. The trouble was that iron pyrite, as every miner knows, is very apt to contain small quantities of arsenical pyrite; and arsenic in the sulphurous gases, in any form whatsoever, will in the course of a few weeks make the platinum contact 'sick,' so that it will no longer act vigorously as a catalytic agent. The Badische works got around this difficulty only by a secret and very complicated process of purifying the gases, using much expensive machinery, and the technique of a wonderfully able staff of chemists. For some years the Peyton Chemical Co. was not able to fulfill the extensive contracts it had made and the Peytons spent hundreds of thousands of dollars more than they had anticipated before they succeeded in making their process practicable. For the last two years, however, they have been supplying all the mixed acids (nitric and sulphuric) used by the Giant Powder works.

In 1903, when I found that there was little hope of obtaining contact acid for the Vigorit works from the Peytons, I sent an agent to investigate the different contact processes in use in Europe and finally obtained the right to use the process of the Verein Chemischer Fabriken, at Mannheim. In the Mannheim process the air and gases from the pyrites furnaces, thoroughly dried, are first passed over iron oxide, ordinary pyrites cinders from the furnaces serving the purpose. By this step about 60% of the sulphur di-oxide is converted into sulphur tri-oxide, and, what is most important, the iron oxides combine with any arsenic in the gases. The gases thus purified are then passed over a platinum contact, where most of the remaining sulphur di-oxide (up to 95%) is converted into tri-oxide, and the latter then goes into the absorbing towers. As in the other contact processes, these are filled with sulphuric acid, which dissolves the sulphur tri-oxide better than water; and the acid is kept diluted with a stream of water sufficient in quantity to combine with the anhydride to form the grade of sulphuric acid that is desired. In August, 1903, the California Vigorit Powder Co. sold out to the 'trust' and I retired from the 'blow-up' business, so that the contact plant I had planned was never erected. But the Mannheim process has since been put into use by the Pacific Coast Oil Co., at Point Richmond, where immense quantities of strong acid are consumed in the refining of petroleum, and has been a great success. The California Powder Works is now completing a plant at Hercules to manufacture acid by the same process, and will doubtless supply both the California and Vigorit-Judson works. The Mannheim process has been used by the Nobel dynamite works in Great Britain since 1903, and several plants have recently been built in the eastern United States. The sulphuric acid yielded by the contact process has been the means of considerably increasing the yield of nitro-glycerine, of which I shall make further mention.

(TO BE CONTINUED.)

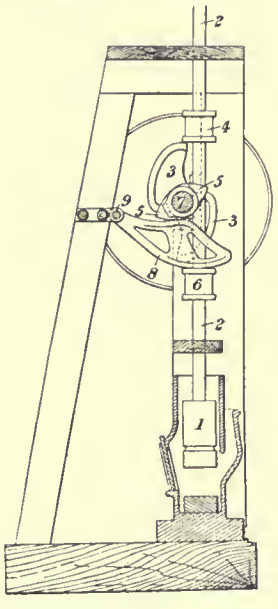
THE volcanic peak of Aconcagua, in Chile, is 23,000 ft. high, and Cotopaxi, in Peru, is 19,660 ft. high. These cones are situated on a high plateau, and therefore their height is not due to volcanic eruptions alone. But the elevations of Mauna Loa, in Hawaii, 14,000 ft., and Mt. Etna, 11,000 ft. high, are due entirely to this cause; while Mt. Shasta, in California, 14,100 ft., and Ranier, in Washington, 14,111 ft., are almost entirely due to volcanic action.

CONSIDERING the Mississippi as an average river in erosive power, the rate of continental erosion is about one foot in 5,000 years. At this rate, to remove an average thickness of 6,000 ft. would require 30,000,000 years.

MINING AND METALLURGICAL PATENTS.

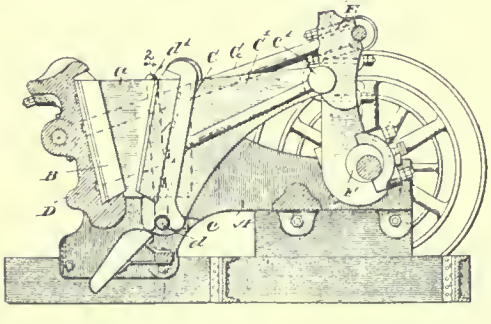
Specially reported for the MINING AND SCIENTIFIC PRESS.

DOUBLE-ACTING STAMP.—No. 844,847; George W. Beynon, Mortimer, and Gardiner H. Mackillop, Maidenhead, England; said Beynon assignor to Gustave Richard Bonnard, London, England.



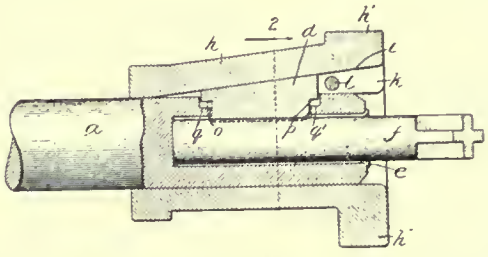
In double-acting stamp-machines and the like, a stamp-head, a stem carrying the same, and two tappets arranged on said stem, in combination with a pair of lifting-cams and a pair of downward-impulse-giving cams carried by one shaft, the lifting-cams being adapted to act on one tappet, and the downward-impulse-giving cams being adapted to give, through the other tappet, and adapted to act, in combination with an intervening lever, upon the other tappet, to give a downward impulse at each descent of the weight.

JAW-CRUSHER.—No. 845,028; Morton G. Bunnell, Chicago, Ill., assignor to Western Wheeled Scraper Co., Aurora, Illinois.



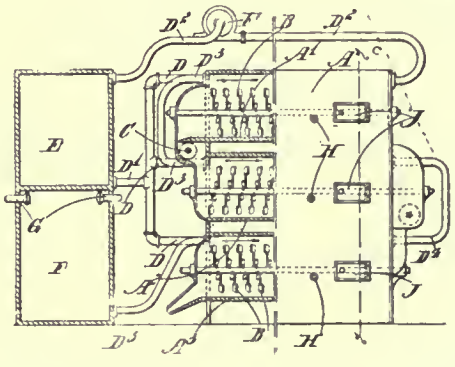
A crushing-machine comprising a suitable frame or body, a stirrup made or formed in one piece and hung inside the crusher frame or body, said stirrup being left free to be raised from the frame or body; a movable jaw provided on its under side with a transverse groove adapted to receive the lower transverse portion of said stirrup, the jaw in this way resting upon the stirrup and the latter supporting the jaw for forward-and-back or vibratory movement, and the jaw being left free to be raised from its swinging support, cheek-plates arranged at each side of the hopper of which said jaw forms a part, the vertical portions of said stirrup being arranged to swing or vibrate in recesses formed between said cheek-plates and said frame or body, the upper laterally projecting portions of said stirrup resting in grooves or concave seats formed on the upper surface of said frame or body, and a vertically reciprocating pitman adapted and arranged for actuating said jaw, the pivotal connection between the jaw and pitman being arranged at a point on a level, or substantially on a level, with the top of the jaw-face, and the power and motion thus communicated to said jaw causing the latter to move back and forth and permitting the resistance offered by the rock to hold the jaw down in place and thereby prevent it from rising from the stirrup upon which it rests.

DRILL-CHUCK.—No. 844,631; Robert Temple, Denver, Colorado.



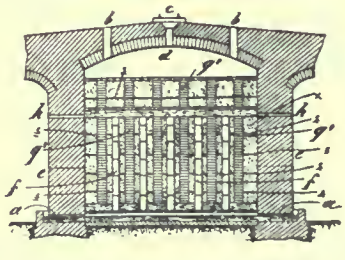
A drill-chuck comprising a socket member provided with a longitudinal bore for receiving the tool, a sliding collar mounted on the socket member, said collar being provided at one end with an outwardly extending circumferential flange, and means engaged by the collar and the tool to secure the tool in operative position, the flanged end of the collar extending beyond the tool-receiving end of the socket member.

PROCESS OF TREATING REFRACTORY ORES.—No. 841,657; Leslie V. Atkinson, Carshalton, England.



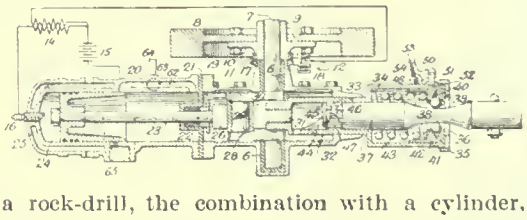
A process for the treatment of refractory sulphide ores consisting in roasting the ore, returning the gases given off by it into the furnace and alternating the admission of such gases into the furnace with air, and spraying weak acid upon the ore in the furnace.

ROASTING OF PYRITOUS MINERALS.—No. 840,253; Giovanni Rambaldini, Miniera di Boccheggiano, Italy.



The herein-described process for treating minerals which consists in effectually crushing the materials for treatment, limiting the maximum size between 10 and 15 millimetres, obtaining the greatest possible quantity of granular material, roasting the same and separating the granular portion.

HYDROCARBON ROCK-DRILL.—No. 842,246; John V. Rice, Jr., Bordentown, New Jersey.

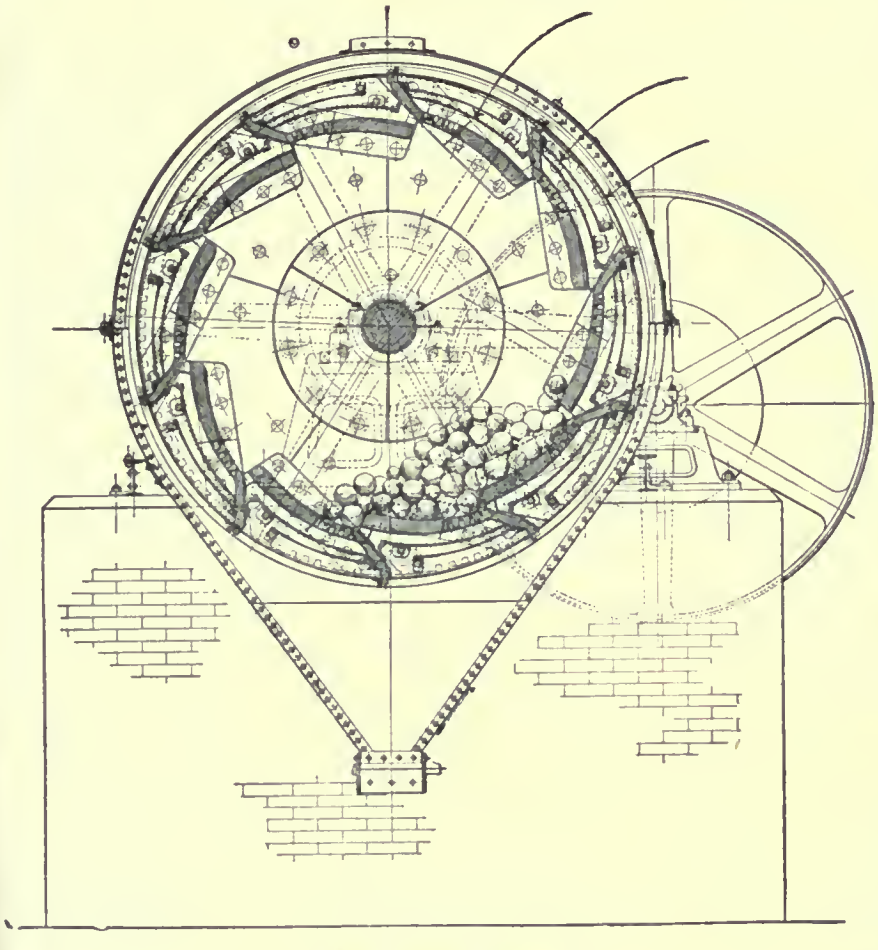


In a rock-drill, the combination with a cylinder, of a piston in said cylinder, a piston-rod, a fly-wheel, means actuated by said piston-rod for actuating said fly-wheel, a tube carried by said rod, a yoke at the forward end of the piston rod, a drill-carrier yieldably mounted in said tube, crank-arms with cross-pin playing in the yoke and a fly-wheel.

The Allis-Chalmers Ball-Mill.

In this machine, the driving-hub or spider at the feed end is made of steel casting, with three blade-shaped arms set diagonally so as to assist in throwing into the mill materials fed through the spider. This spider has three ample feed-openings and is securely keyed to the main driving-shaft, and bolted to the side plate by counter-sunk head-bolts passing through ring-plate and spider.

The driving-hub opposite to the feed end is made of cast iron, properly bored to fit the shaft and securely keyed thereto. The wear incidental to the grinding is to be taken on special steel plates made for the purpose of withstanding this particular use. The holes for the perforated section are cored so that the drilling of small holes is avoided, permitting the use of a harder plate. Wearing plates are three inches thick at the point of greatest wear. They are planed and drilled to template so as to make all repairs for these mills interchangeable. Each breast-plate is made in two portions, one constituting a perforated and the other a solid section, thus enabling the operator to replace one section when worn out instead of replacing the entire plate when only one section is worn out.



The Allis-Chalmers Ball-Mill.

Each Allis-Chalmers ball-mill is provided with a Gates automatic feeder, adjustable so that the quantity of material fed may be varied through a range of from zero to 50% above the rated capacity of the mill. The adjustment of the feeder is so arranged that it can be accomplished without stopping the mill.

An engineer of the Allis-Chalmers Co., who was for some years employed in Australia, gives the following interesting facts regarding the use of ball-mills (with forged steel balls) at one of the leading reduction works in the Kalgoorlie district, where the economies effected by this method of fine grinding have been particularly noteworthy.

The process there began, as a rule, with the breaking of the ore in a Gates gyratory crusher, but it was found that the ball-mills gave excellent results when fed directly with ore 3% of which, by weight, would not pass a 6-in. ring, and 75% of which would not pass a 2-in. ring. The mills with feed of even this character were capable of furnishing 33 tons of product, each, per 24 hr., such as would pass a 20-mesh screen. A mesh determination on the finished product of the ball-mills gave the following results:

	Per cent.
That retained on 40 mesh	24.1
That passing through 40 mesh and retained on 60	9.4
" " " 60 " " " " 80	6.2
" " " 80 " " " " 100	6.6
" " " 100 " " " " 150	3.2
" " " 150 " " " " 200	4.2
" " " 200 "	46.3

It will be observed that nearly half of the material was reduced to a state of division finer than 200 mesh.

One steel ball weighing 18 lb. added daily (24 hr.) to each mill preserves the balance of steel in the mills, while the grinding-plates and side-liners are replaced in complete sets every 7 or 8 months at a cost of less than $900. Each mill revolves at 25 r.p.m. and requires 24 i.h.p. The aggregate weight of the steel balls in each mill varies from one ton to 22 cwt. Of course, even better results are obtained when the ball-mills are working on the product of the Gates crusher, and that is the most economical method; but the above test is cited to show what mills equipped with forged steel balls are capable of doing alone.

The ore crushed at the plant mentioned is calcareous and silicious. A number of analyses of it have averaged as follows:

	Per cent.
Silica	40 to 50
Alumina	13 " 16
Ferric sulphide	6 " 10
Ferric oxide	7 " 10
Carbonate of lime	15 " 20
Magnesia	4 " 7

Traces of copper, lead, zinc, and arsenic are present. This ore carries no free gold, the precious metals present being in the form of tellurides.

That these mills have not found more ready acceptance by the operators of metallurgical plants is probably due to the fact that some difficulty has been encountered in obtaining balls that can be relied upon to wear evenly. The chilled-iron or cast-steel balls do not possess this quality and, as a result, the effectiveness of mills using them has been considerably reduced after the balls have begun to lose their shape. With the forged-steel ball, however, this defect has been overcome, and there can be no doubt but that their introduction has opened up many new fields of usefulness for ball-mills.

Commercial Paragraphs.

THE MIDVALE STEEL CO., of Philadelphia, Pa., announces that they have opened a branch office in the City of Mexico. Mr. John E. Strachan, who formerly was in charge of the Denver office, will be manager of the City of Mexico office. The head office for the Pacific Coast, for The Midvale Steel Co., is located in San Francisco, Mr. Jas. C. H. Ferguson being sales agent.

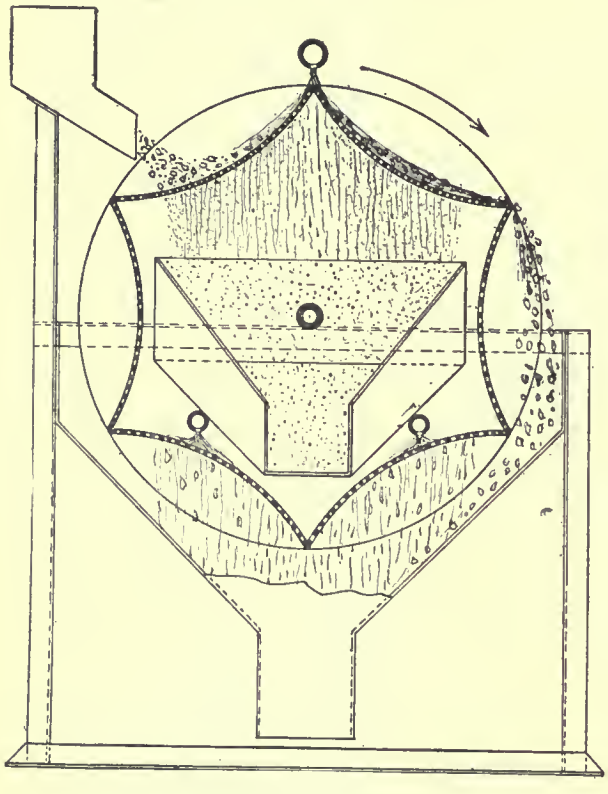
THE HENRY TROEMNER CO., of Philadelphia, recently shipped a 5,000-oz. bullion balance for the use of the Assistant Treasurer of the United States at San Francisco. This balance when loaded with its full capacity shows a sensibility of 0.01 of an ounce and is a counterpart of eight balances which were furnished a short time ago to the U. S. Mint at Denver by the same manufacturers. Among the recent shipments by the same firm was a 10,000-oz. balance to the mint at North Tientsin, China.

The King Revolving Screen.

Mr. H. G. King, the inventor of this machine, furnishes the following description of the screen and the mode of operation and is authority for all statements it contains:

The King screen is a revolving one with a hexagonal cross-section, the sides being curved inwardly toward the centre on a radius equal to that of a circumscribed circle, forming with its proper hoppers and outlet spouts a self-contained machine of the smallest dimensions, highest efficiency, and largest capacity that has heretofore been attained in any type of screen.

Referring to the accompanying diagram, it will be seen that, instead of being fed from the inside and screened outwardly, the King screen receives its feed from the outside, the fine finding its way to a stationary discharge hopper inside of the screen. Water is fed to the machine through a perforated pipe directly over the top of the machine. A parallel branch of the same pipe forms the stationary shaft on which the screen revolves, at the same time supplying an ample spray of water on the inside of the screen, effectually preventing all blinding of the meshes. The screened



The King Revolving Screen.

product is received in independent hoppers, which may be made to spout in any direction desired.

In first cost there is a saving when compared with other screens of equal capacity. This results from the extreme simplicity of construction and the adoption of easily replaceable wearing plates on all exposed surfaces. The wear of screen-cloth, one of the most irritating factors of increased milling cost, is reduced to a minimum.

The trifling wear of the screen-cloth was a genuine surprise both to the inventor and the manager of the mill in which the screen was first installed. It was found that the cloth seemed as good as new after 5,000 tons of ore were run over it during six months. This, however, is readily understood, when comparison is made with other types of screens. On the shaking screen the ore is carried forward by jerks, and hits every wire with oft-repeated blows, and in revolving screens the ore is carried up on the side until overcome by its own gravity it slides down to the bottom of the screen, only to immediately begin again the same constant grinding on all the wires exposed. When the ore falls upon the King screen its motion is practically stopped and the abrasive action very slight.

A constant trouble with all other screens has been the wear upon that part of the cloth that receives the feed. This small portion of the total surface is always exposed to the dropping of all ore handled, and the life of the screen is short. This trouble is entirely eliminated in the King screen, as every square inch of its surface shares alike in resisting this wear caused by the falling ore.

A greater efficiency and capacity is attained than with any other known screening device. The effective screening area of the King screen amounts to 33⅓% of the total area of the screen, whereas the effective screening area of the ordinary trommel seldom, if ever, exceeds 16 to 18% of the total area.

No slime is made on the King screen, while all revolving screens that are fed inside are veritable tube-mills, producing a large proportion of slime, and the shaking screens are the worst slime-makers of all. It is only necessary to add that with the gentle motion of the King screen there is none of the violent friction and abrasion that takes place between the particles of ore in other screens, and especially those of the shaking or vibrating type.

The King screen always keeps its meshes open, the inside spray accomplishing this more effectually than the old-style knockers of the trommel screens, which by the blows and the reactions wedge particles of ore still more tightly in blinded meshes just as often as they free them. The easy, gentle motion of the King screen, the absence of jars, and the action of the internal sprays prevent blinding and present a screening surface constantly open and ready for business.

This machine is almost self-operating on the principles of an overshot water-wheel, and after once starting, requires only the small fraction of a horse-power, which is more, in fact, for regulating the speed than for driving. A one-inch belt is used, no bevel gears, right-angle drives or extra counter-shafts being required.

As a concrete example, we may give the following comparison between the costs of screening in cents per ton, the first column showing the performance of an ordinary trommel screen and the last that of the King screen, both screens handling the same kind of ore through the same size meshes:

	Ordinary Trom. Screen. Cts. per ton.	King Screen. Cts. per ton.
First cost	0.20	0.12
Labor changing cloth	0.11	0.03
Screen cloth	0.14	0.05
Power	0.13	0.01
Lubrication	0.02	0.01
Attendance	0.40	0.25
Total	1.00	0.47

The King screen thus effects a saving of over 50%.

The Hendrie & Bolthoff Manufacturing & Supply Company are sole agents and are in a position to supply all orders at once. They will gladly show the King revolving ore screen to any mine or mill man who will call on them, or to any one who will send them his name and address they will send their new King screen catalogue.

Trade Treatises.

HENDRYX ELECTRO-CYANIDE CO., of Denver, issue Catalogue No. 3, describing the Hendryx process, and the machinery required for that purpose.

INGERSOLL-RAND CO., of New York, publish Form 46, being a descriptive catalogue of the Rand rock-drills. It contains a number of handsome illustrations.

THE BLAISDELL CO., of Los Angeles, publish Catalogue F, describing the automatic cyaniding machinery, in the manufacture of which this company has won a deserved reputation.

POWER & MINING MACHINERY CO., of Milwaukee, issue a handsome pamphlet on cement-making machinery, in the form of Catalogue No. 7. The enormous growth in the manufacture and use of cement makes this publication valuable to engineers.

JOHN A. ROEBLING'S SONS & CO. have re-printed an article from the *New York Herald* describing the model city of Kinkora, which has been built by them for their employees, ten miles below Trenton, N. J. It is an excellent example of enlightened business management.

Editorial.

AMONG our market quotations we now give the average daily prices of copper, lead, spelter, and silver at New York. Those who are buying or selling ore will find these quotations reliable, and we expect that in due course of time they will use them in making settlements.

A KENTUCKY COLONEL once remarked that water would rot a sponge; the watering of stock is a form of financial irrigation in which E. H. Harriman appears to be peculiarly proficient. It is said that the electrification of the Chicago & Alton is impossible because of the certainty of a short circuit; at all events, in trying to explain the overcapitalization of that railroad, he got into deep water.

GREENWATER may have no profitable mines, as yet, but it has a well-printed clever little paper named *The Death Valley Chuck-Walla.* It is owned by its editors and therefore is possessed of an independence of spirit that we admire, even though it has found cause for objecting to a few of our remarks on Greenwater, and expresses that objection vigorously in the issue just to hand. We hope our contemporary may strike it rich—not green stains of copper, but solid sulphide ore running 25 per cent, at least.

POLITICAL CONDITIONS in the Transvaal affect the future of the mining industry, because the importation of Chinese is a debated question. The grant of popular government has resulted in the election of a majority of Het Volk, this being the Boer party, which is opposed to Chinese labor. It is a striking proof of the generosity of Great Britain that the ministerial front bench in the new Parliament will be filled by the generals of the late Boer army. Thus, within six years after the war, the vanquished are again in the saddle, as leaders of a scheme of government granted by the victors. It remains to be seen whether in this case generosity is allied to good sense. The spectacle does honor to the race.

THE POSTHUMOUS notes on silver-lead smelting by T. S. Austin are of great interest. It is a melancholy fact that while he lived, he was not permitted to contribute to metallurgical literature, because the persons by whom he was employed held the opinion that secrecy as to the practice at their smelters was necessary. Such narrow notions still prevail at some smelting establishments and retard the progress of technical science. On the whole, the secretive people are the chief losers, for it is certain that there is no better way of getting information than of giving some yourself, to encourage the others. We are aware that among the larger corporations, in control of a number of reduction works, it is the custom to distribute the data obtained at their various plants among their managers, encouraging them to

compare results. But as the operations are under the direction of a small group of men of similar ideas, there is nothing like the ventilation of the subject or the interchange of ideas that would come from publication in periodicals that are read by independent men on the outside.

Black Sands Again.

We are in receipt of the report on the investigation into the 'black sands' of the Pacific Coast, as published by the Geological Survey and prepared by Dr. David T. Day. It has been demonstrated that such material in its natural state contains from nothing to a few cents per ton in gold, and that if concentrated it will assay many dollars, according to the degree of concentration. Some fragmentary experiments in steel-making were made. A few makers of machinery have been advertised, and several promoters have secured ammunition for pernicious schemes, based on alluvial deposits of questionable value. The general fact of the loss of gold, and possibly platinum, in placer mining has been known for thirty or forty years, but a method of turning that loss into profit in a practical fashion has not been vouchsafed by this report or any other like it. The occurrence of rare earths in the sea-beaches is as well known as it is that gold exists in the water of the ocean; the learned Doctor only worries practical people by his academic effort to emphasize the amount of it. For instance, we received a letter from the owner of a hydraulic mine, informing us that a cubic yard of gravel had been tested by Dr. Day and that it had been demonstrated that there was more than twice as much gold in it as the average yield of the mine. Any young graduate from a school of mines will tell this investigator that one sample will not give the general average of the ore of a whole mine. In the same way, a yard of gravel is taken, the heavy particles are concentrated, and the result is a rich product, which is quoted at so many dollars per ton of concentrate, when it ought to be stated in terms of cents per ton of the crude stuff. In many of the cases quoted in the report, it is noted: "Concentration not known." Then the sample is worthless, except to incite fraudulent enterprises and to excite exaggerated hopes. Any tyro knows that in the gravel of any gulch there can be found all sorts of beautitul things, from shot that was aimed at rabbits to gold rings that missed their destiny. To tell the working miner that his gravel contains gems, platiniridium, josephenite, and tantalite, is magnificent, but it is not ecouomic geology. Even quartz sand, we are informed, is valuable, and garnets have their use as abrasive material. So they have; charcoal is identical chemically with the diamond, and the pearl is but a blister. The whole affair is out of proportion. What the miner and the public generally want to know is how to improve the present methods of extraction so as to minimize the losses in gravel mining. In that direction nothing has been done by Dr. Day that is worth recording. "The Doctor threw up his hands and quit," so one old digger of our acquaintance declares, "right when he should have put on his boots, and McCluskey took the night shift."

Geological Survey for Colorado.

We have been favored with a copy of the bill for creating a State Geological Survey in Colorado, together with another bill dealing with the appropriation for such a department. The main provisions are that the State Geologist shall be the head professor of geology in the State University, his assistants are preferably to be teachers of geology in the State educational institutions, the offices of the Survey shall be at the University, the salary of the State Geologist is to be $500 per annum as executive, plus $8 per diem when doing field work, but the entire sum to be appropriated for the purpose of paying the Geologist, his assistants, their traveling expenses, and other expenditure incidental to the work, is to be $5,000. Finally, the advisory board is to consist of the Governor and the presidents respectively of the University, School of Mines, and Agricultural College of the State.

This is a truly pitiable outcome of the effort to establish a Geological Survey in Colorado. From our own acquaintance, extending over twenty years, of affairs in Colorado, we do not hesitate to say that the advisory board is ill chosen. A Governor rarely knows anything about geology or the application of it, but there are obvious reasons why he must be chairman of such a board; to that we cannot object. The president of the School of Mines is eminently fitted to advise, but what about the presidents of the other two State institutions? Presidents are fussy people at the best, and a board composed of three of them would be a dignified futility. However, even that feature is not so important. There is the provision that the State Geologist is to be the professor in the State University. Some professors are eminently fitted for directing geological investigations, some are not; in fact, a good teacher is rarely an effective executive.

The State University is at Boulder, and the office of the Geological Survey must be there also—a manifest inconvenience. Denver is the place for it. Next, although not conditioned, it is suggested that the assistants are to be teachers from the State institutions. Here we see trouble for the Geologist, who naturally may want men less academic to help him in his practical work. These provisious seem provincial, and a little humiliating to our notion of a useful geological department, which ought to be assisted by men that have knowledge of the exploitation of ore deposits and the actual search for them. Finally, we come to the appropriation, of which we do not hesitate to say that it is a disgrace to Colorado. Five thousand dollars per annum all told for a Geological Survey of Colorado! The thing is ridiculous. A State that produces fifty million dollars worth of metals and minerals every year is to devote $5,000 for a scientific iuvestigation and recording of its geological features. If that is the best that Colorado can do for its mining industry, it is time to acknowledge that the value of science is unknown in that great mineral region, and that its people are so dense to their own interests that they will not encourage the applicatiou of geology to their basic industry.

Mexican Mine Labor.

On another page we publish some sensible observations on mine labor in Mexico, by a writer who is familiar with practical work in the Southern Republic. It is an interesting subject and is particularly important at this time, when the labor supply in so many mining regions is acknowledged to be deficient. On the whole, we consider the employment of native workmen more economical than foreign labor in Mexico. And this holds good in other countries; it is usually best to make the most of the material at hand. The Negro in the mines of the South, the Korean at the Oriental Consolidated mines, the Kaffir in the Transvaal, are examples of the utilization of an indigenous labor supply. Of course, the Mexican is a poor hammersman, and rarely uses his pick as he ought to; but he can be taught; a little patience and a good foreman can do a great deal to improve his methods. It is well recognized that they are excellent blacksmiths, though better at shaping than at tempering the drills. They are small men, and as a rule have the physique of an American boy, rather than that of a well-grown man; but they are strong in unexpected ways, and are capable of being made most efficient miners. To this task the superintendents of foreign companies ought to set themselves, for the time is coming when a scarcity of white labor and a rise in the price of the native supply will create a problem, the solution of which lies close at hand, in the training of the native to greater efficiency. Nearly a hundred years ago Englishmen began to exploit mines in Mexico, and with their machinery and more advanced methods, they also introduced their own workmen. It was a costly blunder, on the whole. Both the European and the American tends "to go to pieces" in the tropics and among colored races; the cheapness of various intoxicants, the laxity of morals, the lessening of self-respect far from home, provoke dissipation of many kinds and injure the sturdy manhood that gives dominance to the white race. Finding himself among a servile population, the white workman begins to depend upon helpers, until a mechanic must have a *peon* to hand a monkey-wrench to him, and, in fact, he will do nothing that a native can do for him. The white man loses his temper and becomes a dull instrument of industry. This was the lesson of the English experience of three generations ago, and it is the experience of the American companies today. To balance it, the training of the native is the only remedy. And in the doing of this there should be no narrow spirit. A manager will say to himself: What is the use of teaching my Mexican employees, when they will leave me as soon as they have been taught and go to some other fellow's mine? Then, let the "other fellow" also improve the methods of his men until there is a plentiful supply of the right kind. There is now so much Anglo-American capital in Mexican mining enterprises, that it is worth while to attack this problem in a proper spirit, so that the condition of affairs that is crippling operations on the Rand may not be duplicated, for example, at El Oro, Pachuca, Guanajuato, Zacatecas, or Chihuahua.

The Canadian Mining Institute.

The annual convention of the Canadian Mining Institute was held at Toronto last week at the King Edward hotel, commencing on March 6. About 150 members were in attendance including many mining men and geologists of continental reputation. George R. Smith, the president of Thetford mines, Quebec, occupied the chair.

In his address the president enlarged upon the rapid development and growing importance of the mining industry, quoting statistics to illustrate its marvelous expansion, especially in Ontario, and expressed the hope that smelters would soon be established in Canada to obviate the necessity of shipping ore abroad for treatment. He also hoped that Quebec would before long have railroad facilities extending to its mineral belt in the north.

A report of the mining section of the Geological Survey of Canada, showing the mineral production of the Dominion for 1906 was presented, from which it appears that the total production (including $300,000 estimated value of products not returned) was $80,000,048, as compared with $69,525,170 for 1905. The metallic production of 1906 was $42,979,629, made up as follows: Copper, 57,029,231 lb., $10,994,095; gold, Yukon, $5,600,000, all other gold, $6,423,932; iron ore exports, 77,778 tons, $149,177; pig iron from Canadian ore, 101,660 tons, $1,724,400; lead, 54,200,000 lb., $3,066,094; nickel, 21,490,955 lb., $8,948,834; silver, 8,568,665 oz., $5,723,097; cobalt, zinc, and other metallic products, $350,000. Increases are shown in nearly every item, the only important exceptions being gold and petroleum. There were specially large increases in silver, nickel, copper, and portland cement. Ontario has assumed a first place in Canada in silver production, owing to the development of Cobalt. British Columbia, on the other hand, shows a slight decrease, owing to the falling off in the Slocan. The expansion in the value of the copper product amounted to nearly $3,500,000, or 47%. British Columbia and Ontario were the two main contributors, furnishing respectively about 79 and 18% of the total. Throughout the whole country the increase in prices has stimulated the search for new deposits and the re-opening of old mines. The production of nickel from Sudbury ores has made rapid growth during the past two years, the output for 1906 being over twice that of 1904. The following are the results of operations last year: Ore mined, 343,814 tons; ore smelted, 340,059 tons; matte produced, 20,364 tons; matte shipped, 20,310 tons; copper contents of matte shipped, 5,264 tons; nickel contents of matte shipped, 10,745 tons; spot value of matte shipped, $4,629,041. The total production of pig iron in 1906 from both Canadian and imported ore amounted to 548,141 tons, as compared with 525,306 tons in 1905. The total of iron ore produced in Canada last year was 269,511 tons. The coal output, which has increased steadily for 12 years, was 9,916,177 tons, value $19,945,032, an increase of 1,248,229 tons over 1905. Nova Scotia produced more than 60% of the total. The salient feature of this industry in 1906 was the great development in coal-mining in the West, more particularly Alberta. There are now six collieries in that Province, each having an annual production of over 100,000 tons. The total quantity of portland cement made in Canada was 2,152,562 bbl., as compared with 1,541,568 bbl. in 1905.

J. M. Clark, of Toronto, read a paper on 'Royalties on Minerals in Ontario,' prefacing it with the remark that although pertinent to the subject, it was written before the proposal to tax mines had been made by the present Government. The paper pointed out the disas-

trous results of such legislation in the past. Many years ago there was a considerable interest in the Hastings district in Eastern Ontario. This resulted in the imposition of royalty on gold, which gave a decided check to the growth of the industry. The royalty was abandoned and a statutory declaration introduced, declaring mining lands and ores free from every royalty tax or duty. Again, when interest became aroused in the mineral resources, royalties were re-imposed in 1891, but confined to land sold or granted after May 14, 1891. The result of this legislation was to make it practically impossible to interest foreign capital in exploration, and the royalties were in consequence repealed. The writer contended that in view of the statutory declaration still appearing on the statute book, proclaiming mining lands and minerals free from royalty, that to impose a tax on them would be a breach of faith toward investors. The fact that the characteristic ores of the Province were low-grade and requiring large amounts of capital for their development called for grave consideration of the problem and immense injury would result if the inflow of capital were seriously checked. The discussion which followed occupied the remainder of the session. The convention was practically unanimous in its opposition to the tax. A resolution was adopted to the effect that the bill was opposed not only to the mining interests, but to the manufacturing and agricultural interests of the Province, and asking the Government to take time to consider carefully what has been the effect of similar legislation in other countries. It was also resolved that the members of the Institute as a body wait on the Government and present the resolution. President Smith, J. E. Hardman, A. M. Hay, R. W. Leonard, and J. M. Clark, were selected as spokesmen of the delegation.

The members of the Institute then proceeded to the legislative buildings, where they were received by Mr. Frank Cochrane, Minister of Mines, and other members of the Government. After listening to the arguments advanced, Mr. Cochrane announced that it was the intention of the Government to proceed with the bill, which had been demanded by the press. He contended that the mining interests had had ample notice of the intention of the Government to impose a tax. The only modification that would probably be made would be the allowance of a rebate upon iron ore smelted in Canada.

In the evening J. C. Gwillim, of Kingston, Ontario, read a paper on 'The Status of the Mining Profession,' dealing with the evil of wild-catting. He suggested action by the Institute to prevent the publication of prospectuses containing statements not vouched for by some person of recognized standing, and restrictions on advertising. In the course of the discussion which followed, Eugene Coste said that the Government should not charter companies capitalized nominally for millions of dollars without having absolute assurance that they were bona fide.

Other papers read were by Eugene Coste, on 'The New Tilbury Oil Fields,' and by H. H. Stoek, of Scranton, Pa., on 'Anthracite Mining Methods in Pennsylvania.'

The next morning session was devoted to the Cobalt area, the first address being given by Willet G. Miller, Provincial Geologist of Ontario, entitled 'Notes on Some Additions to the Map of Cobalt.' He prefaced it with a retrospect of the early discoveries, and pointed out the position and characteristics of the various rock formations, indicating the possibilities of further discoveries. The ore already taken from an area of six square miles has made eight or ten millionaires and has given to 25 or 30 persons fortunes of between $25,000 and $300,000. So far about 100 veins have been discovered that are, or seem likely to become, productive; in Saxony, the similar formation had 300 producing veins.

C. R. Van Hise, president of the Madison University, Wisconsin, spoke on 'The Geology of the Cobalt District,' and at the outset expressed his high appreciation of the faithfulness, accuracy, and correctness of the work of the Canadian geologists. The Cobalt deposits illustrated the formation of ore deposits by more than one concentration. He was of the opinion, as regards most of the ore deposits in the United States, that there had been at least two periods of concentration—the first under deep-seated conditions resulting in the deposition of the arsenides, sulphides, etc., and a period of secondary concentration resulting from the circulation of surface waters. His observations at Cobalt confirmed this view. The cobalt minerals were the results of the earlier concentration; the silver minerals came in later and precipitated the silver. A noteworthy feature of the Cobalt deposits was the extraordinary variation in richness. This irregularity in distribution, illustrated by the finding of large silver nuggets, was the result of two concentrations. It was explained by veins having become shattered and the silver afterward deposited in solution. The finding of rich nuggets on or near the surface was attributable to the rocks of the upper strata having been worn down by erosion, scattering the silver. It was, however, a problem to what extent the lower horizon was the result of concentration under deep-seated conditions and whether secondary concentration had occurred there also. He believed that it had, but the question was not yet solved. The exceptional conditions at Cobalt were associated with the intrusive sheet of diabase, which was the source of the mineral. The diabase had intruded at a time when conditions were favorable for ore deposition, forming cracks and fissures in the older rocks, wherein the cobalt and silver minerals were precipitated. Under such conditions it was to be expected that the diabase would be found productive adjacent to the conglomerate and slate, which was just where the richest deposits were found. The precipitating agents were, he believed, in the conglomerates and Keewatin. If these conclusions were correct they had an important bearing on explorations, as deposits were most likely to be found within a reasonable distance of the diabase. But it was possible that ore deposits might occur in the conglomerate and Keewatin with no diabase, owing to the latter having been eroded. Kerr lake was the contact of the diabase and conglomerate. The horizon beneath the diabase was a legitimate field of exploration, but any ore deposits there would be the result of deep-seated concentration, unaffected by secondary effects. Prof. Miller said that as the veins passed from the conglomerate into the Keewatin, the silver died out, the veins continuing to yield cobalt and nickel. The solutions carrying the silver could work through the conglomerate, but not through the Keewatin.

In the afternoon the consideration of the question of mining taxation was resumed and a resolution was adopted declaring that while the mining industry had no objection to necessary taxation if equitably distributed and collected, provided vested rights were respected, it did object to a royalty tax, because it was confiscatory in its nature, impossible of collection except by an intolerable system of inquisition, and certain to prevent the investment of capital. It concluded by asking for the appointment of a commission to consider the bill.

In the evening there was a banquet at which Mortimer Clark, the Lieutenant-Governor of Ontario, presided. Among the speakers were Frank Cochrane, W. J. Hanna, A. M. Hay, James F. Kemp, and John E. Hardman.

Personal.

BEN. B. LAWRENCE is in Cuba.

WALTER P. JENNEY is visiting Salt Lake.

GILMOUR E. BROWN is at Iquique, in Chile.

R. W. RAYMOND is taking a holiday in Jamaica.

H. VINCENT WALLACE is at Guanajuato, Mexico.

JOHN C. MONTGOMERY has returned to New York.

R. M. BAGG, JR., is now residing at Colorado Springs.

THOMAS RICKARD has returned to London from Russia.

W. R. CROSBY, of Virginia City, is visiting San Francisco.

F. L. BOSQUI has gone to El Paso, Texas, on a short visit.

HENRY KRUMB has returned to New York from London.

GEORGE B. LEE is expected in San Francisco from New York.

LEO VON ROSENBERG has returned to New York from Arizona.

J. H. BELLASIS, lately in Rhodesia, is at Columbia, California.

ELLSWORTH DAGGETT has returned to Salt Lake from New York.

T. F. JAMES is visiting Kansas City from Cumpas, in Sonora, Mexico.

H. A. TITCOMB has returned to London from a visit to St. Petersburg.

MARK R. LAMB is on his way from Guanajuato, Mexico, to San Francisco.

S. W. MUDD is a director of the Mines Syndicate recently organized in New York.

FRANK H. PROBERT has finished his work at Butte and is expected at Los Angeles.

G. W. BORROWE is manager of the Gt. Boulder Perseverance mine at Kalgoorlie.

FRANK L. SLOCUM passed through San Francisco on his way from Chihuahua to Pittsburg.

R. HAY ANDERSON has returned to Mexico City from inspection work in Sonora and Sinaloa.

C. HOPE NICOLSON is now manager of the Lancefield mine, at Laverton, in Western Australia.

H. PENGELLY, formerly at the West End, is now foreman of the Montana-Tonopah mine, at Tonopah.

F. G. T. NICHOLAS has been appointed manager of the Melbourne office of Bewick, Moreing & Company.

DONALD F. CAMPBELL is visiting the goldfields of Nevada in the interest of the MINING AND SCIENTIFIC PRESS.

E. A. H. TAYS has returned from a journey to South Dakota and Montana. Next week he will be in Arizona.

JOHN MORGAN, formerly at the South Kalgurli, is now superintendent of the Oroya-Brownhill mine, at Kalgoorlie.

C. COLCOCK JONES has returned to Los Angeles from an extended professional trip through San Bernardino county, California.

J. C. RALSTON, who underwent a serious operation six months ago at Rochester, Minn., is convalescing at his home in Spokane.

F. KARL LAMB has accepted the position of cyanide superintendent with the Guanajuato Consolidated Co. at Guanajuato, Mexico.

WILLIAM W. PORTER, having severed his connection as a director and officer of the Guggenheim Exploration Co., and the Esperanza Mining Co., announces his association, as president, with the Mines Syndicate.

DAVID BLACK, for a number of years secretary to the Stearns-Roger Mfg. Co., Denver, has resigned, and is now purchasing agent for the Yuba Construction Co., Marysville, California.

ALFRED VON DER ROPP, the manager of the Selby smelter, and to whom the success of that establishment is mainly due, will take a leave of absence on April 1. It is likely that he will choose to make his absence indefinitely long.

Commercial Paragraphs.

JOHN F. MUNN, who has for several years been associated with the Davis-Calyx Drill Co., also with the Cincinnati Core Drilling Co., is now connected with the Cyclone Drill Co., of Orrville, Ohio. Mr. Munn has had a large experience with core-drills in various parts of the country.

THE CYCLONE DRILL CO., of Orrville, Ohio, recently shipped one of their combined core and hollow-rod drilling outfits to Wm. Gelder & Co., of New York, for prospecting their property at Tonopah, Nevada, and a duplicate outfit to O. W. Dunlap, Carlsbad, New Mexico, where a large mineral property is to be developed.

THE C. H. SHAW PNEUMATIC TOOL CO., of Denver, Colo., recently received an order from the Copper Queen Mining Co., at Bisbee, Arizona, for 50 Shaw Eclipse air-hammer rock-drills. This is the second order from the Copper Queen for drills within the past year. In June, 1906, they ordered 50 of these machines.

C. I. GLASSBROOK is local manager for the MINE & SMELTER SUPPLY CO., at 412 Market St., San Francisco. A stock of Wilfley tables is kept on hand for immediate shipment. This company now has branches at Salt Lake City, Utah; El Paso, Texas; City of Mexico; Denver, Colo.; with headquarters in New York at 42 Broadway.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

It is understood that the directors of the Denn and Shattuck-Arizona companies have decided that a smelter will be built for the treatment of the ore from the mines of the companies.——The car famine is decreasing in Bisbee, and last week 100 cars of ore left there in one day. El Paso & Southwestern recently received 500 empty cars for this division, and it is learned that fuel is coming in with greater regularity.——A strike has been made in the Dunn Springs portion of the Paradise district.——The King of Lead property is the steadiest producer in Wood cañon. A shaft is down 250 ft., and a tunnel is 500 ft. long.

There have been no recent developments in connection with the proposed organization of the Western Federation of Miners in Bisbee. At their last meeting, the miners decided that the time had not yet arrived for the election of officers of the local lodge, and they are making no progress in enrolling new members. At the last meeting, 80% of those present were foreigners, and the Federation is apparently losing ground, and is no longer a serious factor in Bisbee affairs. The mining companies are determined not to recognize the organization, and, if necessary, will close all the properties in Bisbee.

PINAL COUNTY.

(Special Correspondence).—Developments in this district are proving satisfactory. Eastern capital has been investing in Pinal county mines, and the resulting prosperity of the district is noticeable. At the Two Queens group, where rich ore was discovered but a few months ago, the main adit has been run 278 ft., and will cut the vein in 34 ft. more. Shipping ore is showing in the shaft.——The Dan O'Carroll property, acquired a short time since by the Drippings Springs Copper Mines Co., and situated near the Saddle Mtn. smelter at Christmas, is being rapidly developed, and is proving valuable. At the Two Queens group of mines a hoisting plant has been installed at the main shaft, and is in operation. Shaft No. 3 is down 38 ft., and has encountered a vein averaging over three feet in thickness. From present appearances it would seem that the ore is likely to continue.

Winkelman, March 11.

CALIFORNIA.

AMADOR COUNTY.

Engineers have been sampling the Argonaut mine, and the new manager is expected to arrive at the property before long. A new shaft will probably be sunk on the Hoffman ground.—— R. L. Chase is the new superintendent of the Lucas mine, he having succeeded F. H. Hammond.

NEVADA COUNTY.

(Special Correspondence).—The Champion and Home mining suit, which has attracted so much attention has been settled and work will be resumed at once. The Champion has purchased the Home holdings, and both properties will be worked through the Champion shaft. The reopening of these mines means a great deal to Nevada City, as a large force of men will be employed. The Champion people will operate upon a larger scale than ever. This property is down 2,400 ft. on the incline, and was a continual producer for years, until 1904, when litigation started. Other valuable property nearby may be consolidated in the near future. Both the Home and Champion mines are well equipped with machinery. They are situated about three miles from Nevada City, upon Deer creek.——The Lincoln mine, one mile east of Nevada City, with a shaft down 80 ft., is looking well. A 16-in. vein has been uncovered, which assays $160 per ton. This mine was worked in former years to water-level, and some good ore was mined.——The famous Pittsburg mine, between Nevada City and Grass Valley, which has been idle for years, is to be opened. The 10-stamp mill is being repaired and a large force of men will be put to work.——The Mayflower mine, at Washington, 18 miles from Nevada City, which has been one of the best producers of that section, has opened a new body of ore and an extra force of men has been put to work. The mine has been well developed, and the company contemplates extensive improvements.——The Midnight mine, which is within the city limits of Nevada City, recently uncovered some of the richest ore ever found in the district. The vein is strong and well defined.——In the southern portion of Nevada county work is progressing on the copper properties, and if the present showings continue, the owners say that a smelter will be erected on the line of the proposed railroad between Nevada City and Marysville.——The Niagara mine, situated a few miles south from Nevada City, is making a splendid showing. The inclined shaft is 160 ft. deep and levels will soon be run. The pay-shoot is about 300 ft. long, and runs from $7 to $18 per ton, with occasional rich bunches.——One-third interest has been purchased in the Round Mtn. mine and an adit will be run.

Nevada City, March 12.

The shaft of the Montana mine will be re-timbered, new buildings will be erected, and new pumps installed. The mine, which has been named the California-Montana, is down 400 ft.——The Primrose mine, near Sierra City, will be worked again, and the 10-stamp mill on the property started.

SISKIYOU COUNTY.

The Oregon Water Power & G. M. Co. will put in a higher ditch to its property below Happy Camp, in order to get more pressure for the giants. The company owns 1,200 acres of mineral land.——The Riccoro Mining Co., operating at Classic hill, is running two giants, day and night.

SHASTA COUNTY.

A new strike has been made in French Gulch by the Bully Hill Co. The property was bonded a year ago from J. L. Cannon and C. C. Fox, and 1,000 ft. of tunneling has been done.

(Special Correspondence).— John C. Montgomery has purchased the Sheridan group of claims from Thomas J. Barbour. One-third of the stock in the new company was then sold to the Balaklala company, and one-sixth of the stock was placed in the treasury, Montgomery and Barbour retaining control. The following officers were elected: T. C. Barbour, president; John C. Montgomery, secretary and treasurer; and C. C. Dorsey, a director.

Redding, March 11.

TUOLUMNE COUNTY.

(Special Correspondence).—A rich strike was made a few days ago on the 1,100-ft. level of the App mine, at Quartz. The two-foot vein on the hanging wall shows free gold, and is reported to run $1,000. It is said that from $25,000 to $30,000 is being taken out daily. From present indications it is believed that this strike will prove to be one of the most valuable ever made in Tuolumne county. H. M. Pease was recently appointed superintendent of the App.—— The unwatering of the Davidson shaft of the Soulsby mine has at last been accomplished, after a year's continuous work. An air-compressor is being installed for operating the machine-drills. Active underground work will be resumed at this part of the mine. The Davidson and Pennsylvania shafts will be connected by a tunnel 500 ft. below surface. Several bodies of high-grade ore have been uncovered during the past year, and the company apparently is satisfied with the outlook. It is reported that the first payment on the purchase price was made recently.—— A 10-stamp mill has been ordered for the Imperial mine, near Jacksonville, and the site on which it will be built is being graded. Within a few days the shaft will have been unwatered, when sinking will be resumed.—— Cutting a station in the Santa Ysabel shaft at the depth of 200 ft. was commenced this week, and driving on this level will shortly be begun. The shaft has been unwatered to the 600-ft. level.——Since the recent discovery of a copper-bearing lode two miles southeast of Jamestown, several prospect shafts have been sunk on the property, and assays show from 7 to 20% copper, and a trace of gold.—— The mill at the Mt. Lily mine, near Columbia, has been started.—— Paul F. Green, owner of El Oro mine, situated south of Tuolumne, expects to have the two-stamp mill that is now being

erected on the property, in operation by May 1. A tramway several hundred feet long that will connect the main tunnel with the mill is being built. The main tunnel is 173 ft. long, and will be continued into the mountain. When it reaches a point in line with the shaft, 100 ft. from the present face of the adit, a raise will be run to tap the shaft. Ventilation of the mine will thus be accomplished. The vein is from 6 to 18 in. wide, and assays from $10 to $60 free gold.

Tuolumne, March 10.

NEVADA.

WHITE PINE COUNTY.

(Special Correspondence).—Ely is a well-built town with good hotels, electric lights, an excellent water supply and good railroad facilities, and is situated in the heart of the Robinson copper district in eastern Nevada. It is one of the oldest mining camps in the State and for several years has been actively prospected by the Guggenheim Exploration Co. for copper. While the copper deposits of this district are not as high-grade or as extensively developed as some of the reports sent out would indicate, some good copper properties are found here, and the future of the town seems assured.——The town has about six thousand inhabitants, and each train brings scores from all sections of the country. Several smelters are being built, but it is probable that, with the exception of the Steptoe smelter, which is being constructed by the smelter trust, not one will be in active operation for some time to come.——The principal properties have been acquired by the Guggenheim interests, although several good prospects are controlled by others. The copper deposits are of great extent, but are low-grade and until the smelter is in operation, development will be necessarily retarded. The Steptoe plant, when working at full capacity, will be able to handle 5,000 tons of ore per day. The estimated cost of this smelter, when completed and ready for operation, is placed at $8,000,000. The plant is being constructed in such a manner as to permit the easy installation of additional furnaces if the production of the mines demands it. Several hundred men are busily engaged in the work of construction and the force will be increased in the course of a few weeks. The lack of building materials has been a serious impediment to rapid progress, but the first unit of the plant will be in operation early next fall.——The principal copper mines are situated at various distances from Ely, but few being close to the city. The most prominent in the Ely district are: The Nevada Consolidated, Ely Consolidated, Pittsburg-Ely, Cumberland-Ely, Giroux Consolidated, and Ely Witch companies. In the Cherry Creek district are the Gold Cañon, Exchequer, Cocomongo, Tea Cup and several other promising prospects. In the Blackhorse district, 30 miles east of Ely, the Amalgamated Nevada properties are promising.——The greatest progress has been made in the Nevada Consolidated, Ely Consolidated, and Cumberland-Ely properties. The formation in those properties is strikingly similar and the ore is usually a sulphide. The veins are of great size and will average 4% copper.——The greatest mine in the district is the Nevada Consolidated, which comprises several properties. This company is capitalized at $6,500,000 and in addition to its mine holdings, owns a half-interest in the Nevada Northern Railroad and the Steptoe smelter. Developments are being pushed on the Ruth and Copper Flat mines and approximately 20,000,000 tons of ore are blocked out. A tunnel is being driven from the Ruth mine to the Star Pointer shaft and is expected to to be completed in four months. A crushing plant will be installed at the Star Pointer shaft and the crushed ore will be loaded into electric cars and taken to the railroad, to be shipped to the Steptoe smelter.——Next to the Nevada Consolidated in value and extent is the Cumberland-Ely property. This company owns 650 acres adjoining the Nevada Consolidated and is capitalized at $6,500,000. This company recently struck the highest grade ore yet encountered in this district in their Veteran claim, at a depth of 430 ft. Drifts and cross-cuts are being driven and the mine is well opened up. The ore assays about 4.5% copper and carries a little gold. This company has a half-interest in the Steptoe smelter and in the railroad being built to the smelter.——Although a younger property than the two already mentioned, the Ely Consolidated gives indications of becoming one of the most important mines in the camp. The company owns 450 acres of mineralized land adjoining the Nevada Consolidated property. Two shafts, the American and Brilliant, have been sunk on the best claims and have reached the sulphide zone passing through some oxidized copper, which assays about 4%, with the usual gold values. While development has not been extensive enough to fully demonstrate the value and area of the ore deposits, such work as has been done indicates that the veins are large and of fair grade. Until the installation of smelters and the coming of cheaper transportation facilities, the low value of the ore will retard production. Ely seems destined to become one of the principal camps in the world.

Ely, Feb. 25.

NEW MEXICO.

RIO ARRIBA COUNTY.

The Tusas Peak Co., composed of Michigan and Wisconsin capitalists, is operating on the Tampa group, near Tusas Peak. The shaft is down 425 ft., and about 1,400 ft. of cross-cutting and driving has been done. A new hoist has been erected, and a Cameron pump is working on the 300-ft. level. A 100-ton leaching plant has just been completed, for treating carbonate ores of copper.

TAOS COUNTY.

It is reported that work will soon commence in the mines in the vicinity of Parsons.——The Silver City Copper Co. has secured control of about 300 acres in the Santa Rita district, where work is being done by the Amalgamated Copper Co. and the General Electric Co. The property is equipped with a concentrating mill, hoisting plant, and a complete working equipment, and one shaft is down 400 ft. The ore carries copper.——The main shaft of the Stephenson-Bennett mine at Organ is down 300 ft., and machinery has been ordered to increase the capacity of the mill from 50 to 500 tons.——It is reported that the Soledad mines in the Florida Mtn. have been sold to the Florida M. & M. Co. The ore carries silver and lead.

Map of New Mexico.

OREGON.

JACKSON COUNTY.

(Special Correspondence).—Tunneling and cross-cutting continues at the Shorty-Hope mine.—— Development work continues on the Golden Spike tunnel, which is in 1,243 ft. The ore at this point has changed in character, showing more free gold. The rich ore-shoots encountered in driving have opened some good ore. The face of the drift is now approaching the south shaft, which is down to the upper

level. A raise will be run at that point for better air circulation.

Ashland, March 10.

(Special Correspondence).—T. W. Hill has been developing a claim in Wagner Creek cañon, four miles west of Ashland, and reports having encountered the lode this week. The work has been done in extending a cross-cut tunnel to tap the vein on the hanging-wall side. The vein was found 140 ft. from the mouth of the tunnel. The same vein had been prospected by a shaft sunk on the dip, on the opposite side of the hill from the tunnel. The shaft is 780 ft. from the end of the tunnel, and a drift is being run on the vein, from the inner end of the tunnel, to reach the bottom of the shaft. This drift along the vein will reach a vertical depth of 800 ft. below the surface, and will give a depth of 1,200 ft. on the dip of the vein. The trend of the vein is north and south, and it will average 20 ft. in width between well-defined walls. A shoot of high-grade gold ore, similar to that found in the old Ashland mine, is known to exist between the shaft and the cross-cut tunnel. This property is a short distance southwest of the Ashland mine, and is on the same vein. The Ashland mine, which was in operation several years ago, was worked to a depth of 1,000 ft. on the incline, and yielded over $1,000,000 in gold, under a costly method of mining. A quantity of the ore contained gold as high as $6,000 per ton. The Ashland mine has been closed down for a number of years, but it would yet be a good paying mine if operated under proper management and with modern machinery.——The Ashland Peak group of gold-quartz claims, situated four miles south of Ashland, on the mountain shoulder of Ashland peak, is being developed by a tunnel run on the vein. The vein averages eight feet in width between well-defined walls. It is uncovered by surface prospect-holes and shafts for three miles along its apex. The quartz is partly decomposed, and contains free gold and sulphides. A 10-in. stratum of the vein on each of the walls contains $60 gold per ton. The balance of the vein will average $2.50 gold per ton, and continues to increase in value as depth is attained. The property can be readily worked by tunnel to the depth of 1,500 feet.

Ashland, March 2.

SOUTH DAKOTA.

The Maitland mine at Garden City is to be incorporated. Heretofore it has been owned and operated by A. Maitland, of Negaunee, Michigan, but he has incorporated it under the name of the North Homestake Mining Co., with a capitalization of $6,000,000. It is reported that the 40-stamp mill will be enlarged to 100 stamps, and it is hoped that there may be a change for the better in the management, which has always been open to criticism. During the past four years the mill has treated 133,162 tons of ore, stamping in cyanide solution. This ore has shown a total value of $1,020,659, or an average battery feed of about $7.66 per ton. The cost of mining and milling is given at $3.31 per ton, but the extraction is only about 70 to 72%. With a capable man with some technical training in charge, there is no reason why this should not be made one of the most profitable of the 'blanket' mines in the Black Hills, although just why it should be called the North Homestake is not apparent, as this mine is in a horizontal, silicious Potsdam sedimentary, which bears no relation whatever to the great mica schist zone at the Homestake, where the ore is practically free-milling.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—In the injunction cases of the Spokane & British Columbia and the Washington & Great Northern railway companies, effecting their rights of way through the Saus Poil valley, for the extension of their lines from Republic to Spokane, the Superior Court has decided the contests in favor of the former. The Washington & Great Northern may appeal to the Supreme Court.

Mining in and about Meteor camp is more active than at any time since the first rush, after the south half of the Colville Indian Reservation was thrown open for mineral entry. The Syndicate M. & M. Co., owning 11 claims, has an adit in 250 ft., and let a contract for 50 ft. more. This company will start exploratory work at once. J. W. Bartlett is the superintendent, and H. D. Presscott, general manager.——A shaft has been sunk on the Queen mine, on a vein of high-grade ore.——The banking firm of Ladd & Tilton, of Portland, has purchased the H. & E. group of four claims and started work on a 500-ft. adit, to cut the vein. M. D. Rankin is superintendent.——The Golden Treasure Co. has driven an adit 300 ft. and expects to tap the vein about 200 ft. farther in.——At the Keystone mine, an adit, in 250 ft., shows the vein to average five feet in width, of low-grade ore, with a width of three feet of high-grade ore in the face.——The Blackthorn Co. has an adit in 300 ft., expects to cut the vein 100 ft. farther in, and is preparing to resume work.——The Stray Dog Co. is hauling ore, assaying in gold and silver about $200 per ton, to the Spokane Falls & Northern railway, for shipment to the smelter.——The Meteor Co. has been taking out ore since the adit cut the vein and will begin shipping as soon as the snow is off. W. A. Halteman is superintendent.——On the east side of the Sherman Mtn. the Gwinn mine is looking well. It has been under bond to Seattle people since last summer and is opened by shaft, drifts, raises, and winzes to the extent of nearly 700 ft. The shaft is down 170 ft., and the drifts from it show the vein to average five feet wide, the greatest width being about 16 ft. The ore is estimated to assay about $45 per ton. An adit, in 125 ft., will be continued 275 ft. farther, and is expected to tap the vein about 300 ft. deep.——The Bridge Creek Mining Co. is developing a vein of silver-lead ore, but has closed down for the winter. It owns five claims on a contact-vein between quartzite and limestone. An adit was driven about 250 ft., 175 of which is on the vein. The ore is galena and lead carbonate and contains some iron sulphide.——A new strike is reported on the Byrne group, at Keller camp, said to be a vein of iron sulphide with chalcopyrite. It was found by cross-cutting from an adit, which it parallels. On one wall, the report says, is a 12-in. streak of galena.——The Dominion Copper Co. has begun shipping ore from the Lone Star and Washington claims, near Danville, just south of the international boundary, to Greenwood, B. C. These claims were purchased a few months ago from the Reservation M. & M. Company.

Republic, March 10.

KITTITAS COUNTY.

(Special Correspondence).—Sylvanite is said to have been found in the Hans Weinegar mine, in a large body of gold-silver ore. This property is situated in the Swank district, near Meaghersville. The company will install machinery during this year.

Republic, March 10.

STEVENS COUNTY.

(Special Correspondence).—Shipments to the coast smelters are now being made from the Old Bonanza mine in the Colville district, north of Spokane, where a well-defined vein has been developed. The new workings are 100 ft. deep and are said to be in a vein that was covered up by the management, ten years ago, the work then being continued by a shaft to a depth of over 200 ft., where a vein of considerable extent and thickness was exploited, with some speculation as to the volume and value of the ore, and was finally abandoned because of the expense of working without proper ventilation, and the low grade of the ore.——Reports from Marcus are that the Little Giant claim has developed six feet of copper ore, east of the old workings, and indications are that the original shaft will be encountered at 200 ft. The new strike runs $150 per ton in gold, silver, and copper, the baser metal predominating. The property is owned by the Domingo M. M. & S. Co.——J. E. Daniels, deputy customs collector at Northport, has received advices from the general board of appraisers at Washington, D. C., removing the duty on zinc in ore, formerly dutiable at the rate of 20% *ad valorem*. This is of importance to Spokane people who own zinc-producing mines in East and West Kootenay, B. C., where thousands of tons are ready for shipment to Iola, Kansas, which is the greatest market in this country.——Harry Shallenberger has secured an option for 90 days on the controlling stock of the Kemp-Komar Copper M. Co.,

which has two claims seven miles nortwest of Loon lake. Some work has been done, including a shaft of 200 ft. Several carloads of 30% copper ore have been sent to the smelters.——New York capital will develop the Mountain Boy group of claims on the south half of the Colville Indian reservation. The property is owned by the Colville M. & S. Co., incorporated for $2,500,000. The Mountain Boy claim attracted considerable attention on account of rich ore.——E. L. Terry, manager of the Reynolds M. & D. Co., which is operating placer mines on the south half of the Colville Indian reservation, has gone to Canada to award a contract on the Gwin mine to continue a cross-cut tunnel in 120 ft., a distance of 400 ft. It is expected to cut the vein at 300 ft. The ore is gold and copper, and it is expected to ship direct to the smelter.——Stockholders of the Advance Mining Co., operating eight claims on the south half of the Colville Indian reservation, at a meeting in Spokane; elected these officers: President, F. Laviginie; and A. M. Campbell, secretary and treasurer. An assessment of half a mill per share on 2,000,000 shares has been levied, to resume operations. Two tunnels aggregating 1,300 ft. have been driven and a winze is sunk 30 ft. below the upper tunnel, giving a depth of 135 ft. below the apex of the vein.

Spokane, Mar. 1.

(Special Correspondence).—The Lead King company in Stevens county, has ordered a tramway and concentrator. The concentrator will handle 75 tons of ore per day, and will be installed and in full operation by August 15, according to the contract. Several ore-shoots have been opened in the property, which is now in condition to supply the concentrator for a long time without further development.——J. R. Ridley of Detroit, Mich., and associates, have bought for $14,000 a group of five placer claims on the west side of Salmon river, opposite the mouth of Slate creek. Mr. Ridley will come west in June and put a force of men at work on the property. Water will be taken from Slate creek, and conducted across the Salmon river by means of a suspension pipe-line.——Directors of the Trade Dollar Mining Co., have arranged with the Revenue company, which is driving the long tunnel to develop both properties, that 25 cents per ton will be paid to the Trade Dollar company for all milling and smelting ore taken out through the tunnel. The contract further provides that the tunnel is to be driven without cost to the Trade Dollar company.

Spokane, Feb. 16.

(Special Correspondence).—A copper ore-shoot, 2½ ft. wide, has been cut in the lower tunnel on the Snowshoe-Snowbird property on Sophia Mtn., 15 miles from Northport, Wash. At a point 350 ft. from the portal of the tunnel a two-inch stringer of quartz was cut. This was driven on for 15 ft., when it widened into the ore-shoot which lies between well-defined walls four feet apart. The property was located 12 years ago by Basile Cortiana. After doing surface work and running a 450-ft. adit, he stopped work.

Harry H. Shallenberger has a 90-day option on the Kemp-Komar copper property, five miles northwest of Loon lake, and 45 miles north of Spokane. There are five feet of ore, which assays 40 to 60% copper, and averages 30% smelter returns in carload lots.

Spokane, March 11.

WHITMAN COUNTY.

(Special Correspondence).—The Bald Mountain M. & M. Co., in the Hoodoo district, is driving on a vein said to assay from 15 to 25% copper.——A shaft is down 300 ft. on the Gold Bug mine, on a vein of gold-copper ore, which assays from $50 to $60 per ton. Drifts have been driven on the vein on the 50, 100, and 200-ft. levels. A spur of the Washington, Idaho & Montana railway is being constructed, and ore shipments to the Tacoma smelter await its completion. A hoist and air-compressor plans will be installed on this property.

Republic, March 10.

BRITISH COLUMBIA.

The shortage of fuel is apparently coming to an end. Le Roi smelter at Northport has resumed operations after a shut-down of several weeks. At Trail, the smelter of the Consolidated company is using another furnace, making three copper furnaces and one lead stack in operation there. In the Boundary district the supply of coal is increasing and the output is growing.

The following is the record of ore shipped and crushed at the Rossland mines for the week ending March 2: Centre Star, 1,590 tons; Le Roi, 2,960; Le Roi No. 2, 595; White Bear (milled), 350 tons. Total, 5,395 tons, or 39,872 tons for the year to date.——The big compressor is being moved from the War Eagle to the Centre Star shaft, and the new hoist has been shipped from Milwaukee.——At Le Roi, there is talk of a rich strike west of the dike, which shows good copper ore.——A carload of concentrates was shipped from the White Bear mill, the result of the treatment of about 350 tons of second-class ore.——A hoisting plant has been purchased for the Inland Empire and will be erected as soon as the snow disappears.——The Trail smelter received 3,942 tons of ore during the week, besides that which came from Rossland. This smelter received from the St. Eugene, Moyie, 150 tons; La Plata, Kokanee creek, 140; Providence, Greenwood, 65; Queen Victoria, Nelson, 43; Iron Mask, Kamloops, 49; Lorna Doone, Silverton, 42; Queen, 23; Whitewater, 35; Lone Bachelor, 21; and Ottawa, Slocan, 20 tons of ore.

In the Boundary district the shipments to smelters were as follows: To Granby smelter, from Granby mines, 9,989; from Skylark mine, 22 tons. To B. C. Copper Co.'s smelter, from Mother Lode, 4,255, and from Snowshoe mine, 1,200 tons. To Dominion Copper Co.'s smelter, from Brooklyn, 1,990; from Rawhide, 1,280; from Sunset, 640, and from Mtn. Rose, 148 tons. To Trail smelter from Snowshoe, 790; from Providence, 30 tons. The total shipments for the week were 20,388 tons, and for the year to date, 123,392 tons.——The Canadian Pacific railway has given notice to some of the Boundary mines that it will not haul any more ore until further notice. This caused the immediate closing of the Snowshoe and the laying off of 40 men. The Rawhide, Mtn. Rose, and Sunset mines, also had to stop shipping.——The Tenderfoot mine, at Copper Creek, near Savona, on the north side of Kamloops lake, has been bonded to Henry Croft, and H. G. Ashby, who have interested English capital in the property.——H. G. Nicholls, the new manager of the Ymir mine, has arrived from London. He reports the satisfactory re-organization of the company, and says work will be started at once.——Plans are being prepared for the enlargement of the Granby smelter, to increase its capacity from 3,000 to 4,200 tons per day.

MEXICO.

GUANAJUATO.

Recent reports state that some of the custom-mills at Guanajuato are saving 92% of the silver and 93% of the gold in the ore.——The Encinallas mine, operating on El Monte system of veins, has been shipping some rich ore.——Some good ore has been struck in the Sirena mine, on the Mother Lode. It is thought that this mine may go into bonanza.——The work on the addition to the Bustos mill at the Cata mine of the Guanajuato Reduction & Mines Co. is about finished. The addition is of 80 stamps, and 80 more will be added soon, making 240 stamps in all. It is estimated that it will take 13 years for the company to mill the old dumps, and in addition to these, it has a great quantity of milling ore which was used as filling in the old stopes in the Valenciana, Cata, Mellado, and Yayas mines of this company.——The Penguico Mines Co. will put in a Butters filter, and a contract for another has been signed by the Mexican Mining & Transportation Co.——Designs are being prepared for a 60-stamp mill for the Tajo de Dolores, and the mill and cyanide plant will be erected as soon as possible.——The Cia. Min. Santa Gertrudis y Anexas at Pachuca, will build a cyanide annex to their hacienda, at once.——The Guanajuato Reduction & Mines Co. is constructing a return-solution line from the cyanide plant to the Bustos mill. The line will be nearly a mile in length, and when it is completed, the company will begin stamping in solution.

DURANGO.

English and French capitalists secured an option some time ago in Los Reyes group of mines in the Guanaceví district of western Durango. It is now reported that they intended to buy the property, for $300,000. The syndicate is a powerful one, and will operate on a large scale

Special Correspondence.

London.

The Chartered Co.'s Report.—Progress in Rhodesia.—New Railroads.—Increasing Gold Yield.—Broken Hill Proprietary.—Big Figures.—Mount Morgan and Its Copper Output.—Another Australian Copper Venture.—Output of Mexican Mines.—Cornish Mining.—Some Criticisms.

Judging from the report of the British South Africa (Chartered) Co. just issued, steady progress continues to result from the operations in Rhodesia. The balance sheet for the year ended March 31, 1906, shows the general expenditure to have been £803,812 and the revenue, £698,043. For the year ending March 31, 1907, the general expenditure is estimated at £802,395 and the revenue at £718,951.

In Northeastern Rhodesia the past year has been uneventful. The conduct of the natives has continued to be satisfactory. Large numbers have been employed in Southern Rhodesia and the neighboring parts of Northwestern Rhodesia, and it is considered that the circulation of the money thus earned cannot fail to have a favorable effect. A hut-tax is now levied over the greater part of Northwestern Rhodesia, and is being paid in a satisfactory manner. An edict has been proclaimed by Lewanika formally abolishing slavery in the Barotse valley. It is hoped that this edict will have the effect of improving materially the conditions of living among the natives, and that it will also strengthen the influence of the administration. Notwithstanding the continued depression in South Africa, the past year in Rhodesia has been marked by increased activity in mining, agriculture, and other industries. The supply of native labor drawn from local sources in Southern Rhodesia remains inadequate for the growing requirements of the country, and as long as there is a scarcity of labor in Rhodesia itself, the directors feel strongly that no recruiting in any part of Rhodesia by the Witwatersrand Native Labor Association for the mines in the Transvaal should be permitted. With regard to railway extension, the main line from Kalomo to the Rhodesia Broken Hill mine in Northwestern Rhodesia was completed in June last, and was opened for public traffic in September. Its construction has involved the erection of a magnificent bridge over the Kafue river, more than a quarter of a mile long. Completing that portion of the Cape to Cairo line has carried the railway into the heart of Northern Rhodesia, to a point situated about 374 miles northeast of the Victoria Falls and about 100 miles to the south of the Congo Free State border. A short extension of the Ayrshire railway for a distance of 12 miles to the Eldorado mine, in the Ayrshire district, has also been completed, and was opened for traffic on July 12. The Victoria Falls Power Co. is already engaged in taking over the various properties that it has acquired, in supplying its customers from its existing plant, and in arranging for the erection of its new works. The board believes that it will now be possible to satisfy the demands for power in Rhodesia at cheaper rates than would have been practicable had it been necessary to undertake this supply independently.

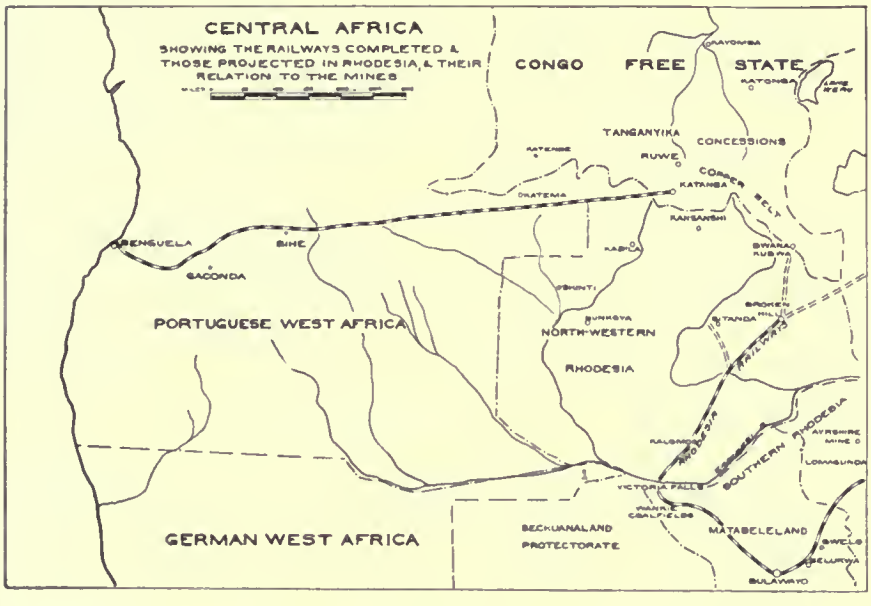
The progress of the mining industry of Rhodesia since the year ended March 31, 1906, has been remarkable. In the gold industry, in particular, a series of new records has been established, the highest production in any one month having now reached a total of 50,127 oz., as against 37,116 oz. in 1905 and 28,100 in 1904. The increase in the total production has been even more satisfactory. In 1906 the total was 551,895 oz., having a cash value of upward of £2,000,000, and showing an increase of 144,847 oz. over the total for 1905, and of 284,158 oz. over 1904. The output of minerals from Northern Rhodesia has also commenced and though, owing to a variety of circumstances, the total tonnage up to the present has been small, there is every reason to believe that the expectations of the Board in regard to the promise of this important mineral district will be fulfilled. Mr. Ackerman has recently visited the Rhodesia Broken Hill mine, the Bwana M'Kukwa mine of the Rhodesia Copper Co., and the Kansanshi mine of the Tanganyika Concessions, and in each case he has given a report which the directors regard as encouraging. The total production of diamonds up to the end of December last was 1,849 carats, the stones being of exceptionally fine quality and commanding high prices. Outside the areas controlled by the Willoughby group a number of prospectors have been at work; but no important finds have been made. Certain alterations have recently been made in the terms given to diggers in the districts that are now engaging attention, and special inducements have also been offered to discoverers of any new fields situated at least 100 miles from any previously known deposit.

According to a cable from the Broken Hill Proprietary, half-yearly statements have been issued showing a profit for the six months ended November 30, 1906, of £314,284, net assets £614,681, and profit and loss account shows a credit balance of £689,046; £22,387 has been expended in construction during the half-year, of which amount £8,991 has been on account of electric power plant, £2,944 electric light, and £2,910 spelter plant. The erection of one unit of spelter plant has been completed, but, as anticipated, further modifications are necessary. The position in regard to the fire is in every way satisfactory; the general manager's latest report is that no further damage is likely. Developments on the 1,200-ft. level are most satisfactory; the quality of ore is fully equal to that on the 1,000-ft. level; the lode has widened more than was expected, and this development has added largely to the ore reserves, which, upon a moderate estimate, are given as 3,000,000 tons, against the previous estimate, in May, 1905, of 3,200,000 tons, since when 828,000 tons have been extracted. The tonnage of ore raised shows an increase over the previous half-year of 64,024 tons, the total being 293,271 tons. The zinc-concentration plant has worked satisfactorily, producing 31,131 tons of concentrate for the half-year; some modifications have been made, the result of which has been favorable, both with regard to working costs and better recovery of the metals. Output for the half-year has been 2,413,066 oz. fine silver, 29,383 tons pig lead, the average prices obtained being, for lead £16 5s. 5d. per ton; for silver 2s. 9.73d. per oz. fine.

An interesting report from the Mount Morgan has also been received for the six months to November 30, 1906. The total revenue for the period amounted to £448,138. The total expenditure has been £271,682. After payment of the regular dividends, aggregating £75,000, and writing £24,699 off plant, machinery, and property, there remains a profit of £78,678. The ore treated at the Mundic works has maintained the value obtained last half-year; but the oxidized ore treated at the West works shows a falling off in value of 5s. 9d. per ton. The copper reduction works have produced 1,751 tons of copper, containing 20,838 oz. gold, which have been shipped to America under advance, in terms of the contract entered into with the Delamar Copper Refining Co. The Board has authorized the erection of an additional blast furnace, extensions to the converter-plant and power-house, and other expenditure referred to in the general manager's report, estimated to cost approximately £125,000. The manager is considering the advisability of erect-

ing an electrolytic copper refinery. With a view to ensuring an abundant supply of suitable ironstone flux, several leases have been acquired and are being opened up. Owing to the increased consumption of water, provision is being made for the additional storage of about 56,000,000 gal. by raising the wall of the No. 7 dam. When the work is finished, the total capacity of all dams will be 376,000,000 gallons.

No slackening of attention to copper mining in Australia is apparent in the London market. It is now reported that as the result of the communications that have passed between London shareholders of the Mt. Elliott mine and the directors in Australia, the latter have decided to recommend that the whole of the assets of the present company be transferred to a new company, to be registered in England, with a capital of £750,000, divided into 150,000 shares of £5 each. Shareholders will receive one fully paid-up share of £5 in the new company for each share of £1 held in the old company, the balance of 30,000 shares of £5 each being held in reserve. The recently formed Great Cobar North Ltd., with a working capital of £100,000, is said to possess a property that is likely to become a large producer.



Mainly as the result of the increase in price of the metal, the Arizona Copper Co. shows an improvement for the financial year to September 30 last, the free profits having been £503,000, an excess of £142,000 compared with the previous year. This has enabled the company to pay dividends this year of 105%. Last year it was 75%. The price of copper obtained for the year averaged about £66 per long ton; last year it averaged £80. The company is not getting up to £109 per long ton. The grade of the ore has fallen, however, to 2.14% from 2.40% in the previous six months, but the main cause of the slow production is the scarcity of labor. When the new mills were all finished and ready to put into operation, the necessary additional miners and laboring men could not be obtained.

The profits are announced for the month of January from Esperanza, Camp Bird, and El Oro, as $188,987, $208,874, and $82,490 respectively. Shipping ore on hand, 1,543 tons. The manager reports that the car situation is very serious; no cars are supplied by the outside roads, and ore is stacked and piled up in every available place. One *patio* remains yet to be filled, but this will hardly handle another week's production. Everything possible is being done, without success.

At the annual meeting of shareholders in the Basset Mines held at Redruth, Mr. Francis Oats presiding, the accounts showed a net profit of £10,427. The chairman said that the present price of tin would encourage mining for that metal in every part of the world. Their directors determined to develop the property as fiercely, he might say vehemently, as possible. He contended that the success of Cornish mining depended upon more extensive development, and its failure could be attributed to the idleness of some of the miners. Cornishmen had been attacked and reflected upon for their alleged conservatism in mining methods. As one who had given his life to mining, he would deny the allegation and claim that at Basset, at any rate, they were proceeding upon proper lines. They could not revolutionize Cornish mining by waving a magic wand and saying presto! These remarks of Mr. Oats were, no doubt, intended for the benefit of present-day speculators who are to be found going up and down in the country seeking to "make a bit!" These invaders wish to see their mines worked for all they are worth—for themselves; they have no sympathy with the traditional keeping of something in hand for the next generation. For them, hand-drilling is wasteful in loss of time, and motive power represented by a combination of windlass and bucket and a wheelbarrow with a man at one end creeping along a plank, is an abomination unto them. There is no question but that the lagging behind with development and output, which has been too apparent during the past year, even with tin at top price, is the danger spot in Cornish mining. In this respect Dolcoath, the leading mine, is as faulty as its neighbors. It may be that the management are holding their hands, until they have struck a bargain with the new 'Lords' anent the resumption of Williams shaft, otherwise it is inexplicable that a shortage in the tonnage should have been allowed during the last six months.

Butte, Montana.

The Affairs of the Raven.—To be Re-organized.—A Curious Story.—North Butte Finds Rich Stuff.—The East Butte Developments.—Butte & London.—Manager's Annual Report.—Encouraging Prospects.—Rapid Shaft-Sinking.

The Raven Mining Co., which had a skyrocket experience about a year ago, will probably be re-organized and its capital stock increased. As was repeatedly asserted in these letters when the Raven was prominent before the speculating public, the company has some excellent property in the Raven and Snoozer lode-claims. The Raven, which has been developed to a depth of only 700 ft., not deep enough to reach the copper deposits, has produced a lot of good silver ore.

The company devoted its work mainly to the Snoozer claim, of which it owns an interest to the extent of six-sevenths, the Butte Coalition Co. owning the other seventh. By an arrangement with the Anaconda Co. the Raven used the shaft of the Buffalo mine, situated south of the Snoozer, the shaft being 2,000 ft. deep, and by a further arrangement with the owners of the Old Glory claim, lying between the Buffalo shaft and the Snoozer claim, the Raven Co. drove a cross-cut from the Buffalo shaft into the Snoozer and opened two veins in the latter ground that were developed at the 800-ft. level, at the 1,200, and at the 1,500-ft. levels. On the lowest

level a lot of good commercial ore was found, but the orebodies were not continuous. A lot of ore was shipped and then, when everything looked bright for the company and its stock had advanced from 50c. to $7.50, the company went into the air. Without notice the Anaconda Co. took its shaft from the Raven Co. and the Butte & Boston Co., another Amalgamated concern, laid claim to the apex and ownership of the vein upon which the Raven Co. had done most of its work and on which it had been mining. W. D. Thornton, a close business associate of the Amalgamated officials in Butte, was at that time president of the Raven, and his close friendship with them inspired public confidence in the Raven. He was blamed for the trick played on the public. All operations by the Raven ceased and no effort was made by the officers to test or dispute the claim of the Butte & Boston. Raven stock went back to 50c. Before the shut-down the Old Glory Co. was organized and one of the owners of that property claimed the second vein opened in the Snoozer and threatened injunction proceedings. He also made overtures for a consolidation of interests, which were not considered by the Raven people.

Raven has been dormant for a year. Now interest has been revived by various rumors, one of which is that the Raven and Old Glory are about to be consolidated and that the Coalition and Amalgamated interest in these properties will be put in with the others to form a new company. As that is so contrary to the known policy of the Amalgamated Co., little credence has been given to the story in Butte, its place of origin being Boston. Propositions to that end have been made by Raven and Old Glory interests, but so far nothing has come of them. Another proposition, on which much effort has been expended, is to re-organize the Raven Co., wipe out its evil name, increase the capitalization, and raise money with which to develop the Raven claim, leaving the Snoozer and Old Glory out of the present reckoning. In the opinion of mining men there is little doubt that at a depth of 2,000 ft. in the Raven a copper vein would be opened. The company is capitalized for only $500,000, but it carries a bonded debt of $30,000.

The North Butte cut two veins in the cross-cut north from the 1,600-ft. level of the Jessie mine, but the first vein is only six feet wide and carries only low-grade ore. The second vein, cut in the Berlin ground, is reported to be about 28 ft. wide and a large portion of it carries copper glance.

The north cross-cuts run by the East Butte on the 400 and 600-ft. levels have opened several good veins, the lower cross-cut having also encountered streaks of copper glance. The south cross-cuts are in almost continuous ore. The company is mining and hoisting ore and making shipments to the Washoe smelter, of the Amalgamated, as rapidly as cars can be secured for the transportation.

A new smelting rate has been secured from the Washoe, the rate being as low as that granted any other mining company in Butte. It will make unnecessary the building of a smelter by the East Butte Co., a project under consideration for some time.

A. A. McMillan, general manager of the Butte & London Copper Development Co., has made his first annual report, in which he covers the first year's work. A three-compartment shaft has been sunk to a depth of nearly 900 ft. One station was cut at 400 ft. and a large one at 800. In sinking the shaft several veins were cut. One of these, says Mr. McMillan, is so promising that the company was asked for a lease on it by some practical miners. However, the lease was refused for the reason that work on the vein might open some new water chambers and let the water down the shaft, thereby making pumping more expensive. The policy of the company is to sink to the 1,500-ft. level before doing any cross-cutting or driving. The reason for going so deep is that on the North Butte Mining Co.'s property, which approaches to within about 700 ft. of the Butte & London ground, they have had to go to about the same depth before finding their great orebodies. The Butte & London Co. has one of the best and most up-to-date plants in the district. It includes a boiler room 36 by 54 ft. with concrete foundation, with four Allis-Chalmers tubular boilers of 125 h.p. each; an engine-room 43 by 50 ft. with an Ingersoll-Sergeant duplex steam-driven air-compressor capable of operating 12 drills; a first-motion hoisting engine on concrete foundation, capable of working to a depth of 2,000 ft.; well-equipped machine and blacksmith-shop, carpenter and timber-framing building equipped with machinery, this building being connected with the shaft by tramway; a modern change and dry-house for miners, fitted with baths of hot and cold water, individual lockers, etc.; a fine office-building, 18 by 36; a head-frame 38 by 60 by 75 ft. high, built of No. 1 Oregon timber, and the plant has been connected with the city water system, fire plugs and hose being installed for protection.

The company has paid out, for all the work, improvements, and salaries to date, $162,808, and has $264,717 in the treasury. Mr. McMillan says the development of the property so far has been exceedingly encouraging. The financial position of the company is said to be satisfactory and the first year's progress more than gratifying.

Goldfield, Nevada.

The Labor Situation.—High-graders Convicted.—Ore Shipments.—Shortage of Mining Timbers.—New Producers.—The Montana-Tonopah Mill.

The labor situation in the Goldfield district is causing some anxiety to the operators. It is not probable that the trouble threatening the camp will come to an immediate head, as the strongest feeling is now between the various labor organizations. The Industrial Workers of the World, which has absorbed the Western Federation of Miners, has become aggressive in an attempt to force the carpenters' union to join them. The men resent this, and a murder attributed to the I. W. W. has aroused the indignation, not only of the carpenters, but also of many miners, who wish to sever their affiliation with the Industrial Workers of the World. As a result of this, all miners and millmen have been called out, and a procession was formed to march through Goldfield to protest against the control of the miners' affairs by unions of other crafts. The miners say that their hours and wages are satisfactory to them. The greatest difficulty now is the opposition of the other crafts. The waiters' and cooks' unions say that they will refuse to serve the miners, if they are independent of the I. W. W., and the labor organizations are making an absurdity of their affairs. It is expected by the operators that the present trouble will soon blow over, and work be steadily resumed.

A jury has convicted two Goldfield men at Fallon, Nevada, of having received, without right, a certain quantity of rich ore from the Mohawk, valued at $5,000. The ore was taken out of Goldfield in a trunk. This ore was identified as coming from the Mohawk mine by the officers of the company. This conviction for 'high grading,' which is one of the first obtained in the State of Nevada, is satisfactory, as it is the receivers of the ore, who reap the greatest profits at the least risk, that have to pay the penalty. Shipments from Goldfield mines

aggregated 518 tons during last week. Of this, 406 tons were treated at the Nevada Goldfield reduction works. The output has been seriously reduced by the lack of mining timbers. At some leases, work has been suspended for this reason. It is expected that several properties will be added to the shipping list next week. These should include the Morton-Beesley lease, the Little Florence, Mohawk Con., Higginson lease on the Jumbo Extension, and the St. Ives lease.

During the past week the following properties contributed to the shipping list: Red Top, Loftus & Davis, McKenzie, Jumbo, Curtis Mohawk, Gold Bar, Combination, and Frances Mohawk.

The report of Mark B. Kerr, consulting engineer for the Montana-Tonopah Mining Co., shows that the mining cost on the ore shipped is $36.25 per ton. The gross returns from 2,315 tons averaged $53.53 per ton, except the last car, which is expected to average $80 per ton. The new 40-stamp mill, designed by F. L. Bosqui, is nearing completion and the treatment of the ore by mill-

Utah.

ing will prove much more economical than sorting and shipping the best of it to the smelters. An extraction of between 85 and 95% of the gold and silver is anticipated.

The process decided upon is as follows: Crushing to ½-in. ring in a series of Gates gyratory crushers, using one No. 5 and two No. 3 machines. The ore is elevated to the mill-bins on a belt-conveyor, whence it passes to eight batteries of five stamps each, provided with 12-mesh wire screens. It is expected that the service of these stamps will be between 150 and 200 tons in 24 hours. The product from these stamps is classified, the coarse material passing to eight Wilfley tables, while the slime and fine go to two Dorr classifiers, which precede the tube-mills. The tailing from the Wilfleys also goes to these classifiers, whence the coarse product goes to the tube-mills for re-grinding. It is proposed to grind to 150 mesh in these mills, of which there are two, each 5 by 22 ft. The re-ground product from the tube-mills joins the overflow from the Dorr machines, and the whole product then passes to two large cone-classifiers. The underflow from these cones goes to 16 Frue vanners, and the overflow joins the stream of tailing from the vanners and runs to the settling vats in the cyanide plant. From the settlers the pulp is taken as required to the agitators, of which there are six of the Hendryx type. After agitating in a cyanide solution, the pulp is drawn off to a large reservoir, where it is stored for filtering by means of the Butters vacuum filtering process. The gold and silver-bearing solutions recovered from the Butters filter will be precipitated on zinc-dust in the Merrill precipitation press, which has been so successfully used at the Homestake mine.

Salt Lake, Utah.

News from Bingham.—New Concentrating Mills.—Dividends.—Activity in Beaver County.—The New Foundland District.—Washouts on the Los Angeles Railroad.

It has been learned from Bingham that the new aerial tramway erected by the Utah Apex Mining Co. recently is giving satisfaction and that shipments of ore are being made to the Salt Lake smelters with regularity. To provide facilities for the opening of the mine at greater depth, the management is installing a new and more powerful hoist. The Parvenue adit has been extended into the mountain 2,360 ft. At present considerable energy is being displayed in exploiting the Leonard vein, lately intersected by the adit.——Rapid progress is being made with the construction of the concentrating mill of the Markham Gulch Milling Co., which is owned jointly by the Utah Apex and New Red Wing companies. The building is enclosed and the installation of equipment is in progress.——The City Rocks Mining Co., with mines at Alta, has succeeded in straightening out some titles to its property and the management has announced that it will soon begin a more vigorous campaign of development and ore extraction.

The Utah Consolidated Mining Co. has announced a dividend of $450,000 for payment to shareholders in April. It has been decided to make quarterly distributions hereafter.——The first two units of the Utah Copper Co.'s new mill at Garfield are completed; but some delay is being experienced on account of the power-plant, which will not be ready for operation for about two weeks. Good headway is being made with the mill of the Boston Consolidated Co., and the management gives assurance that it will be ready to treat ore by the middle of the year.

The Western Pacific has completed the laying of track 125 miles westward from Salt Lake City. The construction of this new transcontinental line and the prospect of another road being built between Salt Lake City and Ely, Nev., has given mining in the Deep Creek district a wonderful impetus and this year promises to witness much mining activity in that region, which covers a large area in western Utah and eastern Nevada.——The directors of the Bullion Beck & Champion Mining Co., have declared a dividend of 10 cents per share, or $10,000, for payment to shareholders during the present month.

There has been considerable inquiry for mining property in Beaver county of late. The great showing that has been made by the Newhouse Mines & Smelters corporation in the Cactus copper mine having stimulated interest in that portion of the State. The Newhouse company will net something over $250,000 during the present month's operations.——The Cedar Mining Co. is shipping regularly from its Beaver county mine, which has been opened to a depth of 275 ft. The company is marketing ore running about $85 per ton.

The Wasatch Copper Co., of which W. D. Pyper of Ogden is manager, is about to begin ore shipments. This company's mine is near Brigham City.——Much activity is reported from the New Foundland district on the west side of the Great Salt Lake. Among the principal properties under development there is the Copper

Mountain mine of the Salt Lake City Copper Co., which is controlled by the Lewisohns of New York.

The ore and bullion settlements reported by Salt Lake banks last week aggregated $602,000.

The washouts along the line of the San Pedro, Los Angeles & Salt Lake railroad in southern Nevada are serious and it is said that the management of the road is contemplating the abandonment of the line through the Meadow Valley wash south of Caliente where the water has played such havoc. The trouble has occurred in exactly the same place as it did a year ago.

Toronto, Canada.

New Silver Districts.—The Tax on Mines.—Shipments From Cobalt.—Developments in the Mines.—Several Rich Strikes.—Machinery for the Laurentian.—Annual Yield of Ontario.—The Output of Cobalt.—Larder Lake.

The area in the neighborhood of Elk lake, which is an expansion of the Montreal river about 50 miles northwest of Cobalt, is proving attractive to prospectors and many have gone there from Cobalt and located claims. A short distance westward lies Silver lake, where some good finds have been made of native silver, and a number of locations have been staked. The rock is described as similar to that of the Cobalt area, being diabase and conglomerate. A great rush to this part is expected in the spring. The first step toward opening up the Larder Lake gold area by railroad communication was taken this week by the Temiskaming & Northern Ontario Railway Commission, which as a preliminary to deciding on the route for a branch line has sent out a party to survey the country between the line and Larder lake. The distance will be less than 20 miles.

The all-absorbing question among mining men just now is the proposed tax on mines and mineral lands, the bill for which has received its second reading in the Legislature, although the amount of the tax has not yet been announced. Strong protests have been made at public meetings and by deputations, but so far no decisive result has been reached. Considering the matter purely from the standpoint of political probabilities, it looks as though the Government in the end would let themselves down gently by accepting the suggestion of the mining interests to appoint a Royal Commission to investigate the whole subject, and in the meantime leave matters as they are.

Shipments of ore from Cobalt for the week ending February 23, amounted to 215 tons from the following mines: Nipissing 50 tons; Coniagas 31; Silver Queen 20; Foster 33; Cobalt Central 17; Buffalo 30, and O'Brien 32 tons.

At the Hunter-Cobalt, directly north of the Green-Meehan, a shaft has been sunk on a vein of cobalt and calcite to a depth of 40 ft. Another shaft at a distance of 200 ft. from the first vein is down 35 ft.——Development work is just being begun on the property of the United States Cobalt Co., adjoining the Nancy Helen. Contracts for sinking a shaft and erecting camp buildings have been let. Stafford Higgins is in charge.——Operations with a diamond-drill on the property adjacent to the Silver Bird have resulted in the discovery of two veins rich in silver and cobalt, four and six inches wide respectively, at 100 ft. below the surface.——The Ontario-Quebec Cobalt Co. reports a strike on its property in Bucke township, about two miles from Haileybury, the ore assaying 4,576 oz. per ton.——Ore taken from the Nado property, owned by the Canadian Central Mines Co. on the Montreal river, adjoining the Edison claim, is reported as assaying 902 oz. per ton. It was taken from an 18-in. vein of smaltite, showing 5-in. niccolite.——At the Victoria mine, native silver has been struck in the main shaft. Energetic development has been carried on under the management of Charles Gifford, formerly of Spokane. As a result of extensive trenching nine veins have been found. A plant is being installed.——The Dufferin Silver Cobalt Co. has done over 1,200 ft. of stripping and has unearthed seven veins, varying in width from 4 to 12 in. Robert Shillington is superintendent.——At the Red Rock the new plant is being erected at the centre of the property so as to work all the shafts conveniently. When the plant is up four drills will be put to work and day and night shifts kept going.——The Cobalt Lake Co. has come to an agreement with the Nipissing, by which the former company will be allowed to sink shafts on the Nipissing property anywhere on the eastern side of the lake. The Nipissing Co. had erected its power-house, crusher, etc. on the Cobalt Lake property, and in consideration of the privilege of sinking shafts from which adits can be run beneath the lake, the Nipissing's buildings are allowed to remain.

Shipments of ore from Cobalt for the week ending March 2 were 291 tons, from the following mines: Buffalo, 30 tons; Green-Meehan, 34 tons; La Rose, 28 tons; Nipissing, 74 tons; O'Brien, 97 tons; and Silver Queen, 27 tons.

A. L. McEwan, the manager of the St. Anthony Reef gold mine, Sturgeon Lake district, has brought bullion of the value of $2,500 to Port Arthur, the results of the last clean-up. The mine is being taken over by a new company, the leading man of which is Mr. Wealock, of Saginaw, Michigan.

There is great activity in recording claims in the mining recorder's office at Haileybury, which is largely due to the rush to Larder lake. Long files of men stand waiting for hours for a chance to file claims or take out prospector's and miner's licenses. Business is active at all points in the Temiskaming country, owing to the mining boom, and everything points to a great influx into this region, especially Larder lake and along the Montreal river. The Larder Lake Proprietary Mines, Ltd., has ordered a plant, comprising a five-stamp mill, 20-h.p. engine, and 25-h.p. boiler. Free gold has been found on the Maple Leaf claim on Dublin Bay at the northwest end of the lake. Twenty men are employed on this property.

The Ontario Department of Mines has issued a report showing the mineral production of the Province for the year 1906, which amounts to a total of $22,221,808, as compared with $17,854,296 in 1905. The metallic production was $13,179,162, and the non-metallic $9,042,646. The money equivalents are based on the value of the product in the form in which it leaves the country, not on the basis of the price of the refined metals in the New York or other foreign markets. If the latter plan were adopted, as is done by the Canadian Geological Survey, the total value would be about $30,000,000. The following table gives the metallic production:

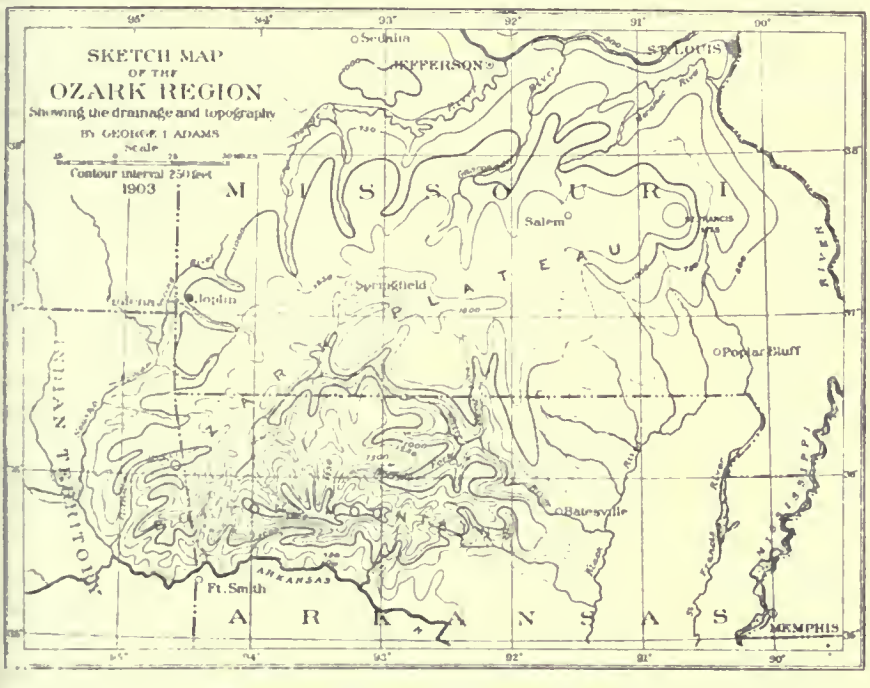
	Quantity.	Value.
Gold	3,519 oz.	$59,274
Silver	5,357,830 oz.	3,543,089
Cobalt	312 tons	30,819
Nickel	10,932 "	3,836,419
Copper	5,910 "	998,548
Lead	.....	93,500
Iron ore	128,099 "	301,032
Pig iron	275,558 "	4,554,247
Zinc ore	400 "	6,000
Total		$13,422,928
Less value Ontario iron ore smelted into pig iron (101,569 tons)		243,766
Net metallic production		$13,179,162

The most noteworthy feature of the non-metallic products is the growth of the portland cement industry, the

output of which was 1,598,815 bbl., valued at $2,381,014, an increase of $597,563 as compared to 1905.

The output of the mines of Cobalt during the year was: Silver, 5,357,830 oz., value $3,543,089; cobalt, 312 tons, value $30,819; nickel, 156 tons, and arsenic, 1,558 tons, values of the two latter not given. Up to the end of 1906 Cobalt had produced: Silver, 8,016,061, value $5,015,479; cobalt, 446 tons, value $150,779; nickel 245 tons, value $13,467, and arsenic, 1,919 tons, value $3,596, the last three items being no source of profit to the mine-owners.

A large quantity of machinery has been ordered by Anthony Blum, general manager for the Hugo von Hagen Exploration Co., for the Laurentian gold mine, on Manitou lake, including a 50-h.p. duplex steam-pump capable of raising 500 gal. water per minute. It will be installed at Crystal lake to supply the mine, the present pipe being sunk below the frost level.——H. D. Alston, managing director of the Manitou Mines Co., has gone East to purchase machinery for the development of the Victory gold mine.



Map Showing Position of the Joplin District.

Joplin, Missouri.

Ore Production.— Continued Increase.— New Strikes in Drill-Holes. More Leases Being Worked.— General Activity.— A New Mill.— Companies Organized.

The highest price reported paid for zinc ore for the week ending February 23 and March 2 was $53.50 for ore from the Missouri Lead & Zinc Co.'s land, and also from the Continental Zinc Co.'s land in Joplin. The highest price reported for lead ore for the week ending February 23 was $87.50 at Granby, and for the week ending March 2, $86 per ton for some choice bins at Webb City and Granby. The car situation seems to get worse, and as a result one-third of the shipment last week from Webb City was made in coal-cars.

Shipments.	Zinc ore. Lb.	Lead ore. Lb.	Combined Value.
Week ending February 23	11,880,600	1,635,170	$351,500
" " March 2	10,975,970	1,931,910	311,957
Up to date	104,313,670	14,670,350	3,049,411
Same period last year	87,582,030	12,325,750	2,437,135
Increase	16,731,640	2,344,600	612,276

Frank Reynolds, who for years was a member of one of the Joplin fire departments, resigning a few months ago, is interested in a mine southwest of Joplin that has become a promising producer. Much development work is reported from Peoria; there has been one turn-in from that new camp already this year, and it promises to make a splendid showing. Harley and Charley Wells, of Joplin, have made a rich strike by drill on a lease of the Henderson land and adjoining the famous Morning Hour property, among the richest in the entire district. The boys have put down two drill-holes, and a 25-ft. face of high-grade ore was encountered in each of them. They will drill a few more holes, and intend sinking a shaft on the most promising one.

James Campbell, of the Missouri Lead & Zinc Co., has purchased from the Muncie Mining Co. the 200 acres known as the Shepherd farm, lying west of the Rex Mining & Smelting Co.'s 1,000-acre tract, and northeast of the Missouri Lead & Zinc Co.'s large holdings. The Fox Mining Co., composed of Thos. Dolan, E. F. Cameron, P. E. Gardner, Hugh Dabbs, J. C. Crampton, and M. H. Fox own a lease of nine lots on the land of the Granby Mining & Smelting Co., situated between Lone Elm and Possum Hollow. This lease has never been prospected, and they have already encountered a body of free ore between the 70 and 90-ft. levels. They have installed a steam-hoist and three hand-jigs, and will enter the list of producers at once.

A company composed of Charles Bartlett, H. Wells, P. Harney, and others, of Joplin, has just put down a second shaft on the Musselman land east of Duenweg. The company has a lease on 20 acres, and has put down nine drill-holes, seven of which showed 20 to 30 ft. of ore-bearing ground. In the first shaft sunk an 18-ft. face of lead was encountered, and in the last, or second shaft, a 22-ft. face of zinc was gone through. It is the intention of the company to erect a modern mill within the next sixty days.——The Goodrich mill, just completed at the George H. mine, owned by the Federated Mines & Milling Co., at Prosperity, was intended to be put in operation Tuesday morning, but Monday morning a gentle March breeze came along and blew down the smoke-stack, delaying operations a few days. The George H. mill has been making some wonderful turn-ins from this property, and so much ore is in sight that it was thought advisable to build another modern mill on the lease. They are working the sheet ground, which means several years' work for both mills.

A. C. Roper, and associates, of Carthage, have leased 100 acres of land belonging to Frank Thompson and Mrs. McFall, situated four miles northeast of Carthage, and will thoroughly test the land by drilling. About 12 years ago it is said five drill-holes were sunk; four of these showed large bodies of zinc ore and a sprinkling of lead. At that time, however, the price of both ores, and especially zinc, was very low, and a disagreement in the company prevented anything being done, but now, with $50 zinc and the mining fever at white heat around Carthage, the value of the land for mineral purposes will be tested thoroughly.—— Parties operating the Eureka mine on the Boston-Aurora ground, at Aurora, who are exploring old workings at 270 ft., have opened up a large face of good zinc ore, and should it continue to show up as good in the next few feet, it will prove to be one of the best properties in that district.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE zinc-tannin process is used to preserve railroad ties.

MORE than nine-tenths of the rocks of the earth's surface are fragmental in origin.

STERLINE is an imitation-silver, containing 69% copper, 13% zinc, and 18% steel.

THE term 'terrane,' or 'terrain,' has essentially the same significance as formation.

ELECTROLYTIC ZINC, running as high as 99.94%, is beginning to find its way into the market.

THE best method of utilizing peat is that of converting it into coke with the recovery of the by-products.

THE principal alloys in which lead is found are those used for solders, bearing metals, and type-metals.

JAW-CRUSHERS are intermittent machines, while spindle or gyratory breakers are continuous machines.

AN assay-slag from the crucible-assay consists in most instances of silicates and borates of the metallic bases.

OZONE is a form of oxygen in which the molecule contains three oxygen atoms, while in ordinary oxygen it contains two.

ALLUVIAL cones are deposited by rapid tributary-streams at the base of the ridges they descend, where they meet the broad plain of the valley.

FERRO-PHOSPHORUS is useful in the basic steel process for enriching the slag. Thin sheet-steel gets a better finish when rolled, if it contains phosphorus.

CORROSION of iron takes place with water and oxygen, but not with water and carbon dioxide. While carbon dioxide is not essential, it may accelerate the reaction.

IN American practice, ore for assay is reduced to a size varying from 80 to 200 mesh. The unit is the assay-ton, which is to one milligram as the short ton is to one ounce Troy.

THE radiant efficiency of the carbon-filament incandescent lamp is only 0.3%. The Nernst lamp has a radiant efficiency of 0.85%, due to increased temperature, and a selective radiation.

THE current quotation for molybdenite is $400 per ton of 95% molybdenite concentrate. The price varies and is a matter for negotiation. In San Francisco, De Golia & Atkins are dealers in rare earths.

UVAROVITE is a green garnet, which contains chrome, replacing part of the iron, and occurs in the Ural Mountains, Russia. This beautiful mineral has been found recently in Shasta county, California.

THE rotation of the stamp, which is accomplished by the friction of the tappet on the cam, is employed to even up the wear on the shoe and die by causing the shoe to drop in a different position each time.

THE difference in crushing by the Blake and Dodge breakers is apparent when listening to the two machines. The Dodge breaker snaps the lumps apart with a report like a pistol-shot, while the Blake works more quietly.

CLASSIFIERS AND SETTLING-VATS are instances of the principle of free settling, which is where individual particles fall freely, either in still water or against an opposing upward current, without being hindered by other particles.

JOINTS in rocks are often due to slow-acting pressure on the outskirts of a region of disturbance. The joints may be parallel, showing that the pressure has acted with no warping of the beds; or, in other cases, warping or torsion may be strongly marked.

IN estimating the first cost of a stamp-mill, the cost of the battery may be placed at $300 per stamp, not including cost of transportation. The foundations will cost $65 per stamp. Roughly, $1,000 per stamp will pay for a fully equipped mill, ready to start.

THE largest use that is made of graphite is in the manufacture of crucibles, muffles, and other articles designed to be exposed to high temperatures. For this purpose the Ceylon graphite possesses special advantages in its low percentage of ash and in its peculiar physical character.

CRUSHING ROLLS are held in position by their journals, act radially upon the lumps of ore, gradually drawing them toward the narrowest space between the rolls, and finally break them by virtue of a compressed force, superior to the breaking strength of the lumps. The ore is therefore broken by compression.

THE advantage in using conical drums when hoisting in deep shafts lies in the fact that as the weight of the suspended rope in the shaft increases, the radius of the drum (through which it acts) decreases, thus equalizing the work on the engine and motor. These drums are used principally for hoisting in balance.

THE dip of a vein, or stratum of rock, is measured by the angle it makes with the horizontal. In the case of a fault, the same idea is sometimes expressed by the term 'hade,' which, however, is measured by the angle the fault makes with the vertical. When both terms are used with reference to the same occurrence, they are mathematically the complements of each other.

THE life of a railroad tie in the United States may be given for:

Chestnut	5 to 12 years	average	7 years
Cedar	6 to 15 "	"	9 "
Hemlock	3 to 8 "	"	5 "
White oak	5 to 12 "	"	7 "
Spruce pine	4 to 7 "	"	5 "

It will often, especially in the case of the softer and more perishable woods, be true economy to preserve them by the injection of creosote, or by other methods. Creosote also preserves the spikes.

REPLYING to the question: Would it be possible and practical to build and wind an electric motor so that it could be run with a continuous electric current of high amperage and an electro-motive force of only two volts, and give good and efficient power results? The answer is that an efficient motor can be constructed along the lines indicated, but it would be a special machine, which none of the larger electric companies would build. A motor of such construction would require excessive size of copper wire to carry the current at low voltage. The tendency to high voltage is for the purpose of reducing the size of the conductors, and the resulting cost of construction.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Cyanidation at Copala, Mexico.

The Editor:

Sir—Enclosed please find blue print which is self explanatory. It was prepared for the purpose of comparing quickly costs at the various stages and also to graphically describe the present system and compare it with others which have preceded it. You will notice that the acid treatment is entirely dispensed with, all zinc shorts being returned to the head sections of the boxes, not only affording us a marked saving in zinc consumed, but also greatly simplifying the process and saving us the cost of acid, extra filter-press, acid-pump, etc.

The precipitation boxes are of eight compartments with bottom-discharge valves. The slime is run into a screening tank through a No. 30 screen. The tank is made in two compartments, separated by a vertical division having its top six inches below the upper rim of the tank, so that when the first division is full the product overflows into the second (leaving, of course, nearly all the precipitates in the first section) and is then pumped through the filter-press. Both divisions have bottom connections to the filter. This arrangement allows the cleaning of all the boxes without interruption, for, as we very frequently get more than a cake of precipitate in three of the four boxes and as we have to clean all of them daily, without this device we would be compelled to empty the filter before we could complete the boxes. Of course, we open up the suction to the first section when we are ready to make cake.

The precipitate, which contains from 18 to 20% moisture, then goes to the dryer and the moisture is reduced to 5%. This dryer consists of an iron cylinder 30 ft. long by 30 in. diam.. having an external fire-box, which allows a uniform heating. A car 24 ft. in length and holding six portable steel trays, containing the precipitate, is run in on a track that also extends a like distance outside the shell to allow easy handling of the product. There is a vent at the far upper extremity of the shell to carry off steam, etc., and the entrance is closed with a steel-hinged door. This device has given every satisfaction, being effective and economical.

The precipitate then goes to the mixing-box, where the flux and binder are thoroughly incorporated and pressed into briquettes, which are then ready for the crucible. Only the No. 300 crucible is used, and a unit charge consists of 220 lb. precipitate with its flux. As the briquettes melt down, more are added, until the crucible has its full charge. *There is no dusting.* Four thousand three hundred ounces are refined as a charge and four charges are run in the same crucible within seven and one-half hours. Dip samples are taken.

The briquetting machine is manufactured by the F. W. Braun Co. and is really intended for the manufacture of cupels. But with a square mold and die, 2.5 by 2 by 1.5 in., it makes a clean hard cake and will handle about 100 lb. per hour.

The precipitation-boxes, screening-tank, filter-press, and briquetting-machine are so placed as to allow a solid concrete floor draining to a small pump near the filter. The entire floor is thoroughly washed with a hose every evening and by a simple bye-pass on the suction this water is pumped through the press. The building is of brick, with white plaster walls extending to within four inches of the floor, where there is a cement collar. This makes it easy to detect any carelessness in handling the product.

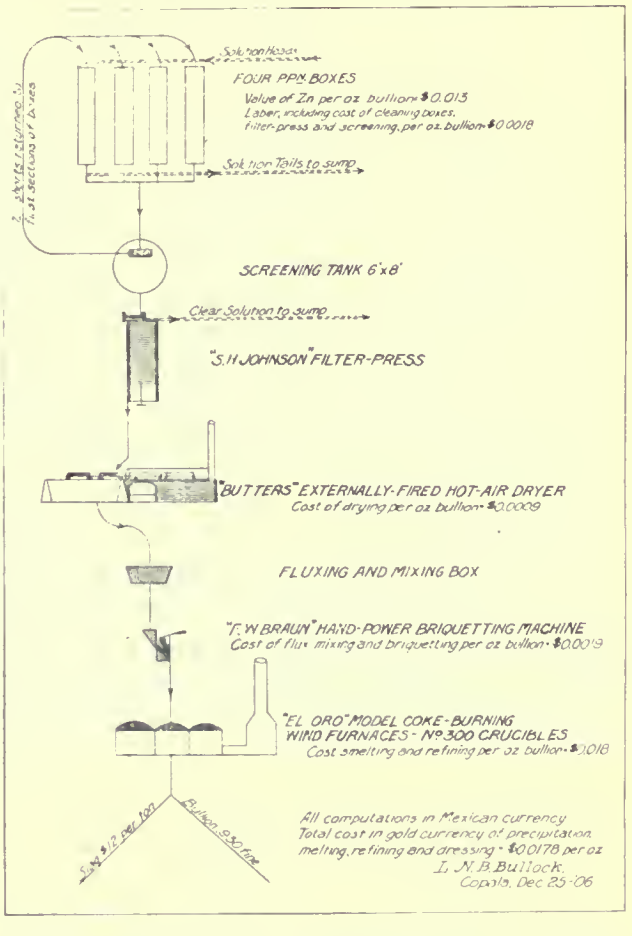
The staff consists of one white foreman and five native boys. On account of the high charges for freighting between Mazatlan and the mines, coke costs us 69 *pesos* per ton; fluxes, zinc, crucibles, etc., are proportionately high, so that taking everything into consideration the cost per ounce is extremely low. We handle on an average about three tons of precipitate per month.

Although this method is far from new, I think there are two or three features of it that are certainly not in general use, namely:

1. Returning all zinc shorts to boxes and thus entirely dispensing with acid treatment.

2. Briquetting product with flux incorporated and smelting same without re-drying (they average 5% moisture).

3. The refining of the bullion in large crucibles, making unit charges of four and five 1,000-oz. bars.



Solution Heads
FOUR PPN. BOXES
Value of Zn per oz. bullion-$0.013
Labor, including cost of cleaning boxes, filter-press and screening, per oz. bullion-$0.0018
Solution Tails to sump
SCREENING TANK 6'x8'
Clear Solution to sump
"S.H JOHNSON" FILTER-PRESS
"BUTTERS" EXTERNALLY-FIRED HOT-AIR DRYER
Cost of drying per oz. bullion-$0.0009
FLUXING AND MIXING BOX
"F. W. BRAUN" HAND-POWER BRIQUETTING MACHINE
Cost of flux mixing and briquetting per oz. bullion-$0.0019
"EL ORO" MODEL COKE-BURNING WIND FURNACES-No 300 CRUCIBLES
Cost smelting and refining per oz. bullion-$.0018
All computations in Mexican currency
Total cost in gold currency of precipitation, melting, refining and dressing-$0.0178 per oz
L. N. B. Bullock.
Copala, Dec 25-'06

The first has been in successful operation for ten months. By first laying, say, two inches of long zinc on the trays of the first section of the precipitation-boxes, then lightly laying the short zinc on top to a depth of 1.5 in. and alternating this until the section is half filled, and finally filling entirely with carefully placed long zinc, we have attained the desired result. All the zinc is consumed and precipitation is perfect.

The briquetting partly does away with the expense of calcining, as the product is dried to only 5% moisture. This product is in every way safer and cleaner to handle and there is no spitting or dusting of the product in the crucibles. The capacity of the latter is likewise greatly increased, unless the comparatively unsafe practice of adding the dry calcined powder to same is followed, which, even when the paper bags are used, allows more or less loss by dusting, etc. In the case of briquettes we add to the crucible without any danger until it is as full as desired.

Mr. Edwin Burt, superintendent of cyaniding for El Oro Mining & Railway Co., Ltd., will bear me out in all of the above, as it was he who first put it into practice

in Mexico, inventiug his own briquetting-machine, a very ingenious device; the above-mentioned company also now briquettes all of its product.

As for No. 3, this means less work and a very large saving in fuel.

I shall finish by saying that the practice here is very satisfactory, the equipment is complete, and the results are certainly economical. It is hoped that you will make use of whatever you see in this short sketch that may prove of value to others, and I shall be glad to read any discussion on the subject.

LAWRENCE N. B. BULLOCK.

Copala, Sinaloa, Mexico, January 12.

[Such contributions from men in practice are of the greatest value; we hope others will 'chip in.'—Editor.]

Sampling and Assaying.

The Editor:

Sir—I would like to ask if any of your readers have had an experience similar to what I am about to describe, and I make the enquiry as much in the interests of those who are examining mines, as in the interests of those who are having their mines examined.

There is a mine not a hundred miles from the Tuolumne river that has been examined by ten experts, among whom are three succeeding managers of a well-known foreign syndicate, two graduates from Pacific Coast universities, one State Senator, and one head assayer for a large Californian mining corporation. Of these ten, five were wise and five foolish; that is to say, five condemned the mine and five recommended it.

Now, as you doubtless know, the usual way for an owner in a case like this is to get up and impeach the motives and ability of those who condemned his property. In this case the representative of the owner, who had been present at every examination, was satisfied that the majority of the experts were entirely honest in their findings and set himself to find a different explanation.

First of all *A* sampled the mine and his results gave between $5 to $6 as an average value for the ore. All *A*'s samples were assayed in duplicate and the mine was re-sampled with the same result.

Next *B* made an examination and his results coincided with *A*'s.

Then *C* came along and only got an average of $3.50 where *A* and *B* had $5 and $6 per ton.

This naturally put *A* on his metal and he went back and sampled over again, with results practically identical to his original findings. He also took one sample and assayed it by five different processes with the result that three gave $5 per ton and two gave only $2. As the half of *C*'s samples had not been taken as a check, however, the trouble was laid to the sampling. At this time several mill-tests were made; these corroborated the assay-results of *A* and *B*.

Next *D* spent six months on the mine, assaying all the time, and his results were the same as those of *A* and *B*.

Then came *E* and *F*; both obtained low results, running about the same as *C*'s. *E*'s samples were assayed by a supposedly good firm of assayers in San Francisco, but they were challenged and a few of them were run by another firm, giving results in every case of 20 to 50% more. *F*'s samples were run by a local assayer, but in this case one-half of all the samples were kept and carefully assayed over again, with the result that where *F* had only been able to get $2.60, the duplicate assay found $5.30 in the ore.

Thus it was demonstrated: (1) That the trouble all along had been in the assaying and not in the sampling. (2) That it was possible for assayers of established reputations, to assay an ore and fail to get all the gold in it. (3) That honest experts sometimes turn down a property through the fault of careless assaying or through the failure to find the assaying process suitable to the particular ore.

The mine referred to is not one of those pockety gold mines that cannot be sampled or assayed. The ore is a silicious slate and carries 7 to 10% iron pyrite whose value when concentrated is from $20 to $45 per ton, and all the values are evenly distributed through the mass. The difference in the results, namely, $3 in a $5 ore, represents the difference between the success and failure in a low-grade proposition.

I shall be glad if you can find space for this and the answers of any of your readers whose experience along the line of sampling and assaying has been similar.

ENQUIRER.

San Francisco, February 23.

[This case is interesting. Our readers are invited to discuss it. Undoubtedly there are some so-called assayers that are impostors, in that they prepare certificates without actually testing the ore, but such scoundrels are rare except in the boom camps. No firm in good standing would play such tricks. It is obviously foolish to send samples to assayers of untried reputation when thoroughly reliable people are available, at the same cost. Whenever it can be proved that an assayer has given returns without assaying the sample, or gives results that demonstrate careless work, the facts should be made known, in order to protect other mining men. In this instance, even with the explicit statement of 'Enquirer,' we fail to understand how so great a difference in the results was possible. It is not possible for a good assayer to "fail to get all the gold" in a sample. That is a fallacy of which abundant use is made by promoters of fake processes—like the Beam, of unlamented memory. Assaying for gold is the easiest kind of assaying to anyone who knows anything about it. We would be sorry to believe that "honest experts turn down a property through a fault of careless assaying, or through the failure to find the assaying process suitable to the particular ore." Honest experts are not so common that we care to think of them being fooled in this way, and, on the whole, we feel assured that such men, being careful in other matters, are careful to choose an assayer known to be trustworthy. In case of doubt, it is easy to send one or two duplicates to another man. As to assaying processes, we repeat that there is no trouble about making a gold assay; when it comes to tin, nickel, cobalt, and other metals less common in the West, the average assayer of a gold camp may be at sea, but in such cases it is obvious that it is best to send the samples to a firm in a big city doing a general business and with varied experience.

The sampling of a low-grade orebody, carrying quartz assaying only between $2 and $5 per ton, is a difficult matter, and, if the ore be patchy, the difficulty is increased. Unless large samples are taken with the utmost care to break a true cross-section of the lode at each place sampled, the results are not trustworthy. In order to ascertain whether the ore is spotty, it is well to divide each original sample into two and reduce each half separately, making two assay samples out of each mine sample. In order to check the assaying, it is essential that the pulp shall be similar and this can only be done by taking the final pulp, pulverized to 100 mesh, and sub-dividing, sending half to one assayer and half to the other. Many discrepancies in assaying are due not to the assayers, but to the actual difference in the content of the samples sent to them, and this is more likely with a free-gold ore than with any other.—Editor.]

Mining in South Africa.—II.

Contributed to the MINING AND SCIENTIFIC PRESS
By J. B. PITCHFORD.

Most of the shafts sunk on the Rand have five compartments. Some are sunk on the dip of the lode which varies from 70 to 35° in different mines, the tendency being for the steeper dips to flatten to about 35° as the mines get deeper. But most of the shafts are vertical. Some new vert cal shafts that have been started for working the deep levels have seven compartments. On the mines of the Consolidated Gold Fields the average rate of sinking eight shafts, each 7 by 28 ft., to depths varying from 1,300 to 3,700 ft., was 100 ft. per month and the average cost $134 per foot. Two of these shafts over 3,000 ft. deep were each sunk at the rate of 152 ft. per month for six consecutive months. The time on the work was subdivided as follows:

Hand-drilling with Kaffirs	3:07 hr.
Hoisting rock	3:26 "
Hoisting men and tools	1:17 "
Blasting	0:50 "
Total	8:00 hr.

Hand-drilled holes per shift	20 to 21
Dynamite per foot, lb.	16 to 18
Coal per shift, lb.	2,400 to 2,800
Buckets of rock (one ton) hoisted	34 to 36

The deepest shaft is the Catlin, about 4,200 ft. The shafts are usually timbered with 8 by 8 in. timbers of pitch pine or Oregon (imported from the States) and lagged with two or three-inch plank. In the hoisting compartments the guides are Oregon pine 4 by 6 in. to 5 by 8 in. Some steel guides are U-shaped; others are T-shaped with extra thick members for the shoes to run on. There are bearer-sets resting on hitches cut in the rock every 100 ft. or less. In some cases steel girders, forming the dividers, are used for bearers.

Each ladder starts from a platform in the pump and electric cable compartments and the mining regulations stipulate that they must all be slanting. They are made of 2 by 4 in. or 3 by 3 in. Oregon pine with round iron or gas-pipe steps about 11 in. apart.

The term head-frame or head-gear is used in preference to gallows frame. For permanent work these range from 75 to over 100 ft. high, measured to the centre of the sheaves. These head-frames are usually provided with bins to separate coarse ore, fine, and waste rock; adjoining them are the crushers and sorting rooms. The crushers are preferably set on an independent framework, so that the vibration will not be imparted to the head-frame. Three methods of sorting are used: The old method of sorting on a floor, revolving steel tables of about 30 ft. diam., and Robins conveying belts. The belt method appears to be the most approved. On a mine having 200 stamps there will be 50 or more negroes (principally young boys) employed at sorting under the direction of one or two white men. Revolving steel trommels are used for washing the ore before it goes on the sorting table or belt. They are about four feet in diameter and 10 to 18 ft. long. The proportion of waste sorted from the ore varies from 10 to 30%. A steel head-frame 100 ft. high with bins, etc., costs $26,000 erected. Automatic self-dumping skips and Templer's shaft equipments are installed on some of the important mines.

On the Rand. Simmer & Jack, No. 2 Shaft.

The ore is conveyed to the mills in various ways. One mine has a railroad and hopper-bottom trucks of 25 tons capacity, and the cost of transport is about three cents per ton. Other railroads pull from two to four ton self-dumping cars at a cost of five to eight cents per ton. The most common method is rope-haulage, which costs from 6 to 12c. per ton. Where the distance is not too great, belt-conveyors are used to advantage.

There are about 7,000 stamps running on the Rand. The largest number in one building is 400 at the joint mill of the Summer East and Knights Deep, and the next largest, at the Simmer & Jack mine, 320 stamps in one building. The mill on the Robinson mine has 220 stamps and three Allis-Chalmers tube-mills. The output from this mine averages $400,000 per month. It has been under the management of W. W. Mein for several years. The crushing capacity of these mills is from five to eight tons per stamp in 24 hours, and it takes seven to

nine tons of water per ton of ore. The weight of the stamps varies from 1,150 to 1,600 lb. The wire screens used vary from 20 to 35 mesh. The coarse screens are used where there are tube-mills. It is customary to install two tube-mills for a 100-stamp mill or three for a 200-stamp mill. The tube-mills are 5 ft. 6 in. diam. by about 20 ft. long inside the silex liners. From 50 to 60% of the gold is recovered by amalgamation; the rest is obtained in the cyanide plant from the concentrate, sand, and slime treatment, except a small quantity that is sent to chlorination works.

Some of the mines use Frue vanners and others use Wilfley tables below the battery amalgamating plates. The product is either sent to the chlorination works or subjected to long-time treatment by cyanide. Shaking amalgamating tables covered with copper plates are used below the tube-mills.

Tailing wheels are used for elevating the sand to the cyanide plant, because the ground is flat. The sand is delivered to spitzkasten where the concentrate is taken out. The material is distributed in the vats by the Butters & Mein's distributor or by direct filling. The concentrate goes to one set of vats and the sand to another set. The concentrate takes about 21 days of treatment and sand about seven days. There are settling-vats and treatment-vats of steel. Classifiers are used for the sand, and the slime-settling vats are provided with an annular launder or trough for leading the water to the return-water reservoir. A solution of cyanide is run through the products and this goes to the precipitation-boxes, where the gold is precipitated on zinc shaving.

The gold and zinc precipitate is then dried, calcined, and melted. The gold-solution is tested on entering and leaving the precipitation-boxes. Filter-presses are becoming more extensively used for slime-treatment. Automatic samplers are employed for sampling the sand. Some of the best methods in the cyanide practice were initiated by Charles Butters, who also supervised the erection of the first large plants.

The most expeditious hoisting done in South Africa is at the Kimberley shaft, of the De Beers mines. Skips holding five tons of blue ground are hoisted 1,840 ft. in 45 seconds, including loading and dumping. The greatest number of winding engines in use in the Transvaal are of the double-cylinder high-pressure type with double drums arranged to run counterbalanced. The steam cylinders range in size from 16 by 36 in. to 28 by 72 in. Some cross-compound hoisting engines are 28 and 50 in. by 72 in. Twin tandem-compound hoisting engines are used on some of the mines and they do excellent work. The Whiting system is used in some instances. A small hoisting engine geared three to one, having two cylinders 13 by 24 in., sunk a shaft to a depth of 3,000 ft., where a record of 203 ft. of sinking was made in one month—the time per trip being 3½ minutes, with a one-ton bucket. The mean effective pressure on the piston of a high-pressure hoisting engine can be estimated to reach 75% of the boiler-pressure. One pound of coal will hoist 30 to 50 ft.-tons of rock with a high-pressure hoisting engine.

Round ropes are almost universally used in the Transvaal. They are usually made with six strands and seven wires to the strand, but sometimes 19 wires to the strand are used where the sheaves are small and great flexibility is desired; and occasionally 13, 14, and 16 wires to the strand. The steel wire is usually from 110 to 140 tons breaking strain. The factor of safety required by the Government mining regulations is six—for all ropes. The comparative breaking strain between crucible steel ropes and plough steel ropes is as 37 is to 48.

The boilers are generally in units of 100 to 250 h.p. and 1,000 to 1,600 h.p. is installed for a mine having a 100-stamp mill. The greatest number are of the water-tube type such as the Sterling, Babcock & Wilcox, and Heine, but there are some Lancashire and horizontal tubular boilers; 800 to 1,600 h.p. of boilers are connected to one chimney by a flue passing around or through economizers. The Weir or Hall compound feed-pumps are generally used. Steam traps are employed extensively. One ton of coal is burned for eight tons of ore mined.

Some of the mines employ the Cornish pumping system. Scarcely any of these pumps exceed 12 in. diam. and 8 ft. stroke. Other mines are equipped with electrically driven pumps, which are more readily adapted to the varying quantities of water in various parts of the mine. Some of these pumps are of the single-acting triple-plunger type driven from motors having reduction gear. Some of the pumps are of the high-pressure centrifugal and turbine type directly connected with the motors. Where strong acid water is encountered lead-lined steel pump-columns are used. Lifts of from 500 to 1,000 ft. are employed with electric pumps and it is rarely safe to exceed 300-ft. lift with the Cornish system; 200,000 to 250,000 gal. per day from a shaft may be near the average on the Rand, but there are one or two shafts that have as much as 2,500,000 gal. per day to contend with. Some of the underground pump stations are 12 by 15 by 25 ft. Armored cables with well insulated and protected wires are used to take the current down the shafts.

The air-compressors are of the compound type ranging from 20 to 75 drills capacity. The principal makers are the Ingersoll Rand, Allis-Chalmers, Reidler, Fraser & Chalmers, and Walker. The rating is based on 100 cu. ft. free air per 3¼-in. Ingersoll rock-drill. The piston speed of the large compressors is from 500 to 550 ft. per minute, and the air-pressure maintained is from 70 to 80 lb. The cubic feet of free air capacity is based on the volumetric intake of the low-pressure cylinder at the rated piston speed.

The rate of drilling is about four to five feet per hour. A 3¼-in. drill takes 12¾ h.p. It takes about 300 lb. coal per ft. for a 5 by 7 drift, exclusive of winding and pumping, estimating the coal to evaporate six pounds water to one pound coal.

Pneumatic hammer-drills are being introduced by Mr. Hellman for stoping. They are very light and can be handled by one man and will do more than six men can do by hand-drilling. There are over 3,000 machine-drills in use in the Johannesburg mines.

Most of the mines generate their own electric power and have two or more generators. Motors are used for the following purposes:

	Kilowatts.
Rockbreakers, sorting tables, etc	70 to 150
Pumping and other work in the cyanide and precipitation house	100 " 180
Returning water from slime dam	20 " 40
Carpenters', smiths', and machine shops	20 " 40
Mine pumping	80 " 150
Lighting underground	10 " 30
Total	290 to 570

At night time, when lights are required on the surface, there will be less motors running than in the daytime; so that for a mine running 200 stamps a fair estimate of the electric power required will be from 500 to 600 kw. unless there is over 250,000 gal. mine water to be pumped per day.

The Consolidated Gold Fields Co. has a central electric plant of about 3,000 kw. that supplies several of their mines. The old Dutch regulation only allowed 3,000 volts to be carried across roads on 24-ft. steel poles weighing 325 to 350 lb. This regulation has been modified

so as to permit of 50,000 volts being transmitted; even this voltage will have to be greatly increased when electric power is brought from the Victoria Falls, a distance of over 600 miles, to Johannesburg, at a cost of several million pounds. The Victoria Falls Power Co. estimates that it can sell the power at a profit for less than it can be generated on a coal mine near Johannesburg, where coal that will evaporate 6 lb. of water per pound of coal can be put in the bunkers for about $2 per ton. As a precaution against accident and to get to business quickly the Victoria Falls Co. proposes to install a good-sized steam-plant near Johannesburg and cheap coal. There are no industries of any magnitude nearer Victoria Falls than Johannesburg, where 50,000 h.p. could be used easily by some of the large mining groups.

Loading a Big Stick of Oregon Pine for Johannesburg; 18 by 18 Inches, 100 Feet Long.

The accompanying illustration shows timbers of Oregon pine, 18 by 18 in. by 100 ft. long, being loaded on railroad cars at Delagoa Bay by the Lingham Timber Co. to be forwarded to the Consolidated Goldfield's mines at Johannesburg. Assuming this lumber to have cost:

In Puget Sound f.o.b. ship	$22.00
The ocean freight to Delagoa Bay was	22.00
The railroad freight to Johannesburg	35.00
Total cost per 1,000 ft. delivered on the mine	$79.00
The value of each timber on the mine would be	$213.30

On account of the high cost of timber, structural steel is now used on the mines at Johannesburg, especially for head-frames and ore-bins.

The compound for the natives is composed of a series of rooms about 14 by 20 ft. arranged in the form of a quadrangle with an open space in the centre. They are built of galvanized iron on wood framing, or brick walls, with galvanized iron roof. The Government regulations require that each native shall have not less than 250 cu. ft. of air. The bunks are made two high and the framework is of angle-iron. The bottom boards are loose, so that they can be taken out for cleaning and disinfecting. The floors are either concrete or asphalt and special natives are detailed to keep these rooms clean. Some compounds are steam-heated and stoves are provided in each room and a coal allowance is dealt out. A separate building is provided for a native hospital. Adequate sanitary arrangements are provided to suit all parts of the mine and surface. The cook-house has a row of cast-iron cooking pots in it. They are about 30 in. diam. and are steam-jacketed. Steam and water-pipes are connected to each pot.

There is a corn-grinding mill where the mealie is ground ready to be cooked into a thick porridge or mush. This is stirred by the cooks and dished out to the natives as they file past. Vegetables are also boiled and each Kaffir is allowed about two pounds of meat per week and some bread. The Chinese are fed chiefly on rice and stewed meat, with vegetables and bread, and are allowed all the tea they want to drink. They are quartered in a separate compound.

Hundreds of diamond-drill holes have been sunk on the Rand and in the adjoining districts for the purpose of prospecting for gold and coal. Some of the deepest holes have exceeded 5,000 ft. The formation is not badly broken, being sandstone, shale, quartzite, and porphyry. It is possible to obtain over 90% of the core for examination.

Some of the very deep holes in Africa have deflected to a considerable extent, especially those sunk on inclines of 45° or over. In nearly every case the deviation was to the right or the direction in which the drill revolves. The deviations were usually surveyed by the photographic method, by the hydrofluoric acid method, or by H. F. Marriott's instrument. These methods have been tried on the same hole and they have checked each

other closely. The diamond-drilling machines used are the Sullivan and Bullock, the former for the deepest holes.

One of the most difficult diamond-drill holes was started at the bottom of a shaft full of water, the shaft being 2,520 ft. deep at the time. A hole was successfully drilled over 500 ft. below the bottom of the shaft and a lode, assaying $10 over a good stoping width, was cut. The Vogelstruis West shaft was afterward pumped out and sunk. The correctness of the diamond-drill work was then proved.

The railroads to Johannesburg are:

From Cape Town	1,000 miles
" Port Elizabeth	700 "
" East London	660 "
" Durban	480 "
" Delagoa Bay	400 "

The best natural harbor is at Delagoa Bay, but this is in Portuguese territory, which supplies half the negroes working in the mines. The gauge of the Central South African railroads is 3 ft. 6 in. and considerable 80-lb. rail is used. Narrow-gauge railroads are a mistake for long-distance hauls when it is considered that the proportion of weight of rolling stock to load is greater than on broad gauges. The running time on a narrow-gauge road cannot be as fast as a broad gauge with the same degree of safety. The road-bed is fairly well constructed and the most important bridges are good steel structures. The running time is slow compared with English railroads.

The rolling stock is generally good. The sleeping cars have a corridor down the side and the dining cars are on the American plan, but all are somewhat smaller on account of the narrow gauge. Some of the hopper-bottom steel coal-cars carry 35 tons. The rates of transport for merchandise and coal per ton mile is about five times as much as in the United States. Coal that costs $1.50 per ton at the pit's mouth costs from $2.25 to $5 delivered at the gold mines, the distance varying from 30 to 120 miles. Transvaal coal will evaporate 5½ to 7½ lb. water per pound of coal. Most of the heavy machinery imported comes by way of Durban and Delagoa Bay, and Oregon pine sticks 18 by 18 in. by 100 ft. have been hauled by rail from the latter place. All Oregon pine comes from Puget Sound and pitch pine from Georgia. Most of the foodstuffs are imported to Johannesburg from other countries and this, together with the machinery and building materials, makes a big business for the railroads.

The railroads are controlled by the Government and the rapid development of this vast country is consequently retarded because the scope for individual enterprise is eliminated from more numerous schemes than any set of Government officials could find time to attend to, even if they had means at their disposal. The Government has no right to risk the people's money in a railroad gamble, but individuals have the right to gamble in railroad building if they see fit, as long as it is not taxpayer's money. All these conditions tend to the slow development of a country whose resources are scattered over a large area. The business done by the railroads to the mines has been immense. The item of machinery alone amounts to over $55,000,000, including cost and transport.

There are a number of coal mines within a distance of from 20 to 130 miles from the gold mines and their annual output is about fourteen million tons.

There are a number of diamond deposits in South Africa. The two large producing mines are the De Beers at Kimberley, whose output in 1906 was 2,211,000 carats, realizing $26,300,000. There are 22,000 natives and 3,700 white people employed by this company. Diamonds have more than doubled in value in eight years. The other large diamond mine is the Premier. It is in the Transvaal near Pretoria. The Cullinan diamond (the largest in the world, 3,000 carats, value over $2,000,000) was found here. The output for 1906 was 1,049,800 carats; 60% of the net output goes to the Government. Dividends were paid amounting to $1,500,000 per annum.

The natives are the happiest and most independent people in the world. When they are discharged, they do not worry at all. They can earn enough in a month or two to keep them a year and they easily acquire extravagant and some other bad habits by contact with white people. A negro who has been all his life with his own people is much more useful for work and far less tricky than one who has had the white man's religion held up to him. It is impudent presumption for white people to pretend to teach African natives morality, for, taken as a whole, they are more moral than large communities of the white civilized races. Some of the tribes used to punish immoral acts by death.

As a rule, the natives are generous and kind to each other and there is little bloodshed among those of the same tribe, but some tribes hate each other by tradition, and if they get to fighting they are vicious. In the compounds on the mines the negroes of different tribes have separate rooms and there is seldom any quarreling unless they get too much drink. The natives employed on a mine only lose about six per cent of their time through drink, sickness, and all other causes, which will bear comparison with white laboring people.

There is enough low-grade ore in the Transvaal to produce $10,000,000 per month that will not pay high enough wages for white labor. Must it stay in the ground? There are millions of colored people in the world that have been raising rice, tea, coffee, sugar, tobacco, and doing other kinds of menial work for thousands of years. The more highly civilized races have received and still continue to receive the benefit of this work. The natives of Africa and others who desire employment that will not pay white people should have the opportunity to take out this enormous wealth, nine-tenths of which would be paid out for machinery, supplies, and labor; and the supervision would give employment to a number of white people.

South Africa is not a good agricultural country and will never be a rich country except for the gold and other minerals and precious stones taken from the mines. The rivers are inadequate for irrigation except for a small portion of the vast land area. There are practically no ranges of snow-capped mountains making rivulets to flow to the valleys. The rain-fall is about 20 to 30 in. and the evaporation from lakes and reservoirs exceeds five feet in a period of nine months. A large amount of the land is either rocky or sandy. Retaining reservoirs for irrigating purposes require to be of an immense size in proportion to the land irrigated, and large catchment areas are necessary. One acre of grazing land in the United States is equal to five acres in South Africa. Wells for irrigation are being bored by Americans in the Orange River Colony, but the farmers only cultivate a portion of their land and are glad to obtain sufficient water for their cattle and sheep.

DROP-HAMMERS, operated on the principle of the pile-driver, are used in the Lake Superior region for breaking large lumps of ore, and cleaning mass-copper preparatory to smelting.

THE erosive power of water, or its power of overcoming cohesion, varies as the square of the velocity of the current.

Silver-Lead Smelting Practice.—II.

By T. S. Austin.

Edited for the Mining and Scientific Press
By L. S. Austin.

Operation of the Furnace.—[In a letter of August, 26, 1888, he says:] Most of my furnace running is done by eye, and one should acquire this faculty. I maintain that it is quite as necessary as the analysis. Analysis is all right when you have good reduction and a slag near the type in the three elements, otherwise you have to trust to appearance in the pot, action in the furnace, crystalization, etc. I would not lower the silica unless the slag showed very acid.

The mechanical and physical part of silver-lead smelting is fully as important as the slag composition. You may have often noticed that slags, very far from correct, have given excellent results in every way, while correct composition is no surety of excellent work. Thus a 'hasher' [one who smelts by guess] may at times get excellent results, unfortunately, for him, without knowing why.

Quantity of Fuel.—Here lies the secret [in connection with the blast] of successful smelting.

Not enough attention is paid by metallurgists to this important factor. I know that formerly I never used to. A certain amount of fuel was always used, often so many scoops-full. The slag, when it came down, often was different from the calculation, then there came the doctoring of the slag with iron or lime to get it right, and that perhaps would be futile. I have seen S—— run a week on an unreduced slag, trying to flux it right, often adding silica to get it acid because it looked fluid, when a good dose of coke would have brought it round inside of 24 hours. Over-reduction is as bad, for it will bring on sows, and make speiss of all the arsenic in your ore. It will give copper sows and crucible trouble without rest. I always weigh my fuel for each furnace. When putting on a new charge, I add a little more coke than might be necessary, so as to be sure to have the slag reduced, for, until it is reduced, you can form no definite opinion of what it truly is. After the charge is down I have my analyses, assays, and physical appearances to guide me, also the working of the furnace. If the slags are under 0.7% I take it that reduction is enough, if 0.3 to 0.4% I know I am verging on over-reduction, for, with too much coke the speed will lessen, and there will be coke at the tap-hole, and tendency to over-fire above the top of the charge. I consider 1% lead in the slag too much, as it tends to greater lead-loss, especially if you run much refuse or foul slag, but it certainly makes pretty running for speed on any slag of fair composition. In reducing fuel, a cut of 1% in the weight of the charge is enough where you are running fair. In going the other way, say where the slag is as high as 2% Pb, I would add much more, say 4% and, when reduction *does* come, it is possble to cut the excess by degrees. Nine times out of ten you will find that when the reduction takes place the slag composition is off. Silica will be high and FeO too low. After the slag is corrected, then you can commence reducing the amount of fuel to suit.

The fuel should be regulated so as to keep the lead assays from 0.5 to 1.0%, but anything that tends to over-reduction is as objectionable as under-reduction. With over-reduction both iron and copper sows will result, and the surplus of fuel, which has to be consumed, slows down the furnace, as well as making crucible-trouble. Your lead assays of slag and matte are guides here. The slag with 0.5% lead I do not consider too low for the proper amount of reduction, while the matte should carry 12 to 15% lead. You will notice when you have poor reduction, with slag from 1.5 to 3% lead, that you will have to very largely increase the fuel-charge to get the furnaces back into a normal working condition. Of course, this is to be done only on those furnaces that are working badly at the time of non-reduction. I notice that furnaces that have been in blast for some time, are more prone to these irregularities.

Amount of Blast.—This important factor goes hand-in-hand with the fuel. It will vary with the state of the furnace, size, or coarseness of the ore, etc. Still it is best to keep the blast constant, and regulate other conditions to it. If reduction is imperfect, a slight slackening of the pressure will often help it. This is because the diminution of blast-pressure retards the furnace-speed, the coke burned per minute is lessened, and more time is given to ore reduction. On the other hand, with slight over-reduction, increase of blast is a good thing, as it gives speed, and the ore is exposed for a shorter time to reducing influences. It is hard to fix the blast-pressure one should adopt, but I believe 18 oz. is a maximum (with a 12 to 14 ft. smelting column) for the ordinary lead furnace. Generally 15 oz. will give all that can be desired on average coarse ore. Speed can be got at that pressure by cutting down rather than by raising blast. I would say drive all you can up to the point of hot-top, but avoid that objectionable feature always. Of course, the more you get smelted in a day the cheaper you are smelting, and never lose sight of that fact. Aim to get your charge coarse by getting lumpy ores, then regulate your fuel so that you use just enough for smelting purposes, burning no unnecessary excess. Under these conditions use blast enough to speed the furnaces up to the capacity of your men, and just short of having a hot-top. You will find, though, with a good state of affairs at the tuyeres, the heat will confine itself to this zone where it is needed, and you will reach the limit of endurance of your men before you get over-fire. I have found that over-fire occurs mostly with slow driving with fine ore.

Mechanical Condition of the Charge.—Fine ore we know is a bad thing. It causes slow running, liability to raw ore at the tuyeres, irregularities, higher silver losses. If you can fuse or even frit it, it is, in most cases, commercially advantageous, as you convert your slow-running material into fast-running material, and decrease the cost of smelting by increasing tonnage. Your fused product takes less fuel to smelt, and gives a cleaner slag. On the other hand fusing loses more lead and silver, so that you might find it better to frit only, especially where you are not crowded with ore.

Condition of Furnace-Shaft.—With a shaft much incrusted, the furnace is subject to sudden variations, and is liable to get off in reduction. Still, by slower running, more fuel, lighter blast, one can do very good work with a badly crusted furnace. It is better economy to bar it off than to continue to run it under such conditions. I always do my barring by blowing out completely. Then, when the furnace is cool, I have it cut down by gads, and have a good job made of it. This is also a good time for general slight repairs.

Collecting Agents.—Lead, iron matte, and copper matte are all good collecting agents. I consider the latter particularly so, consequently if you have a good deal of it, you can run with less fear of silver loss, although you

*These observations of T. S. Austin, recently deceased, general superintendent of the Southern Department of the American Smelting & Refining Co., are compiled from letters written by him to his brother, from 1883 to 1906, covering most of the period of his wide experience in silver-lead smelting, and to some extent that in base-bullion refining. They lack some of his recent experiences, but show that much of his knowledge had been brought into finished form some time before his death. The notes refer largely to his work at Socorro, New Mexico, Monterey and Chihuahua, Mexico, and to El Paso, Texas, together with other technical observations made during that time. Professor L. S. Austin's remarks are in brackets. The first of this series appeared in our issue of February 23.

will be liable to crucibl-etrouble from copper sponge. A good percentage of lead on the charge is a valuable thing, and finally I think the association of lead and silver together in the ore has much to do with clean silver slags.

FURNACE OPERATIONS AT MONTERREY, 1893.—I notice that you have the conditions favoring good blast-furnace work in silver-lead smelting, namely, a good percentage of lead on the charge (over 10%), the presence of copper, roasted material in the charge, and silver and lead associated in the same ore. Here (at Monterrey) I have as a rule no copper, lead 10% of the charge, and with the lead ores nearly silver-free, and the silver ores quartzy and containing but little lead. The result is that it is hard to get and keep a slag properly clean in silver, and unless I run slowly, without forcing the blast, the slag will go right up in that metal. I run a slag of the three-quarter type, but with the CaO largely replaced by ZnO and Al_2O_3, so that I get one of 33% SiO_2, 33% FeO, and 17% CaO; but, unless I am very careful, I get high silver on any approximation to this type. I simply have to avoid high blast and driving, and allow the lead enough time to act fully on the silver compounds. I could never run the blast as you do to 28 oz. and be successful with my slag. My conditions here are indeed peculiar, and, try as I will to overcome the defects, I don't feel successful in doing so. The furnaces are good-running, I have long campaigns, good crucibles, cool tops; everything in fact, save low silvers in the slags, and that is something that defies me. I shall work things round in time, so as to get better ores, or rather, suitable ones, and with the advent of roasting and of copper will come cleaner work.

My opinion is that fast running tends to increase the silver in the slag under certain circumstances, and these circumstances are when the silver and the lead are not allied in the minerals that compose the smelting mixture, that is, if the silver is in a silicious ore on the one side, and the lead in a low-grade carbonate on the other, fast running will induce high-silver slags, because the lead and silver will not have time to come into intimate contact and mixture. If, however, the silver is in a mineral together with lead, as an argentiferous galena, or with lead and copper as gray copper ore (tetrahedrite), or even as a sulphide with other base sulphides, it will be taken up by the lead much more rapidly, and faster running will be permissible. One can readily conceive of a condition of affairs when almost any speed, within reason, would not seriously affect silver-loss in the slag. Thus the lead ores might be largely good-grade argentiferous galena and carbonate mixtures, the silver ores medium or even high-grade quartz ores carrying the silver associated with lead, copper, and iron sulphides. Considerable quantities of roast-product, fused or sintered, might also be attainable, and roasted matte, containing copper, be largely used. In such a case everything, so far as silver is concerned, would be right for fast running, and it should be "a consummation devoutly to be wished." Still 120 tons per day is good big tonnage for a furnace (42 by 120 in.) anywhere, though I think, if the men could stand it, you might do even better. This is my view on the silver question.

As regards lead I hold that one may take an altogether different attitude. The slag assay does not tell the losses. Of course, reduction may be very bad, and the slag-loss will be heavy, and it will be shown at once in the output of base-bullion. This outrageous loss is seen at a glance and almost without the need of an assay. I think you must carry the lead as high as one per cent in the slag to get continued fast running, and aim to avoid over-reduction. Indeed it is here that the metallurgist's judgment and skill come in "the running on the ragged edge." However, if he runs in this way, and the furnace speeds right along, the fume-loss will be minimized and the monthly statement will show less lead-loss than was the case with slow running and low assays of lead in the slag. It is a case of daily care and management. The three conditions are as follows:

1. *Ideal Working.* The slag assay gives medium results for lead, say 1 to 1.2%, the slag is fluid and hot, the speed of the furnace high, the smoke or fume escaping at the throat, light in volume, color gray or dark, base-bullion output good.

2. *Under-Reduction.* The slag is higher in lead, say 1.2 up to 2 or even 3% or more, the slag fluid but cold and red, looking heavy, the speed very high, the smoke thick and much in volume, with a grayish-white color, the base-bullion output bad. To correct this condition there is needed extra fuel, scrap iron, or some other reducing agent, and even a moderate lowering of blast.

3. *Over-Reduction.* The slag is low in lead, say only a few tenths per cent, the speed much reduced and the furnace tightening, the slag slow-running but hot, the furnace-top hot with white smoke when the fire mounts to near the surface, and very little at all when it is quenched back. The base-bullion output is good, but the crucible is liable to get sticky. This condition is to be corrected by cutting down the fuel.

These conditions you have doubtless met and you are aware that they are the main rules for handling a furnace. With high speed there should also be but little trouble in keeping the fore-hearth or settler open and in good condition, especially if you have much matte.

In investigating the furnace operation one should in particular obtain the following data: Blast pressure in inches of mercury, the name or make of blower, its size or number, displacement per revolution and the number of revolutions per minute, and, if possible, the horse-power needed to drive it. This last may be obtained by indicating the engine, both with or without the blower, or, if run by motor, even more easily by readings of the ammeter and volt-meter. The level of the charge should also be given, whether kept to the level of the charge-plate, or with the charge dropped down a bit, the smelting column (distance from tuyeres to charge-plate), the section of the furnace at the tuyeres and above, the nature (degree of fineness) of the charge, the amount of foul slag returned to the furnace, and the kind of slag (as given by analysis) made. The percentage of fuel is to be specified, based upon the weight of the charge, and it must be understood what this charge is, that is, whether or not the foul slag is included, and whether the weights are the dry or the wet weights, and what amount of roasted material is used. The tonnage of the furnace should be given, and it is well to know how the jackets hold out and whether other construction is satisfactory.

EDITORS stand for what is thought and sought. Publishers stand for what is blazoned and bought. Editors represent the abstract. Publishers represent the concrete. Editors interpret the public will. Publishers guard the office till. Editors speak for and to the race. Publishers are concerned with pace and space. The lines of editors go throughout all the earth and their words to the ends of the world. The lines of publishers are agate, nonpareil, or minion, with special terms for displays or cuts. Sometimes publishers disguise advertisements as reading matter. Their wickedness, however, is discovered and, though they may not be condemned, editors are never found guilty.—St. Clair McKelway.

Pockets in the Upper Portion of Gold Veins.

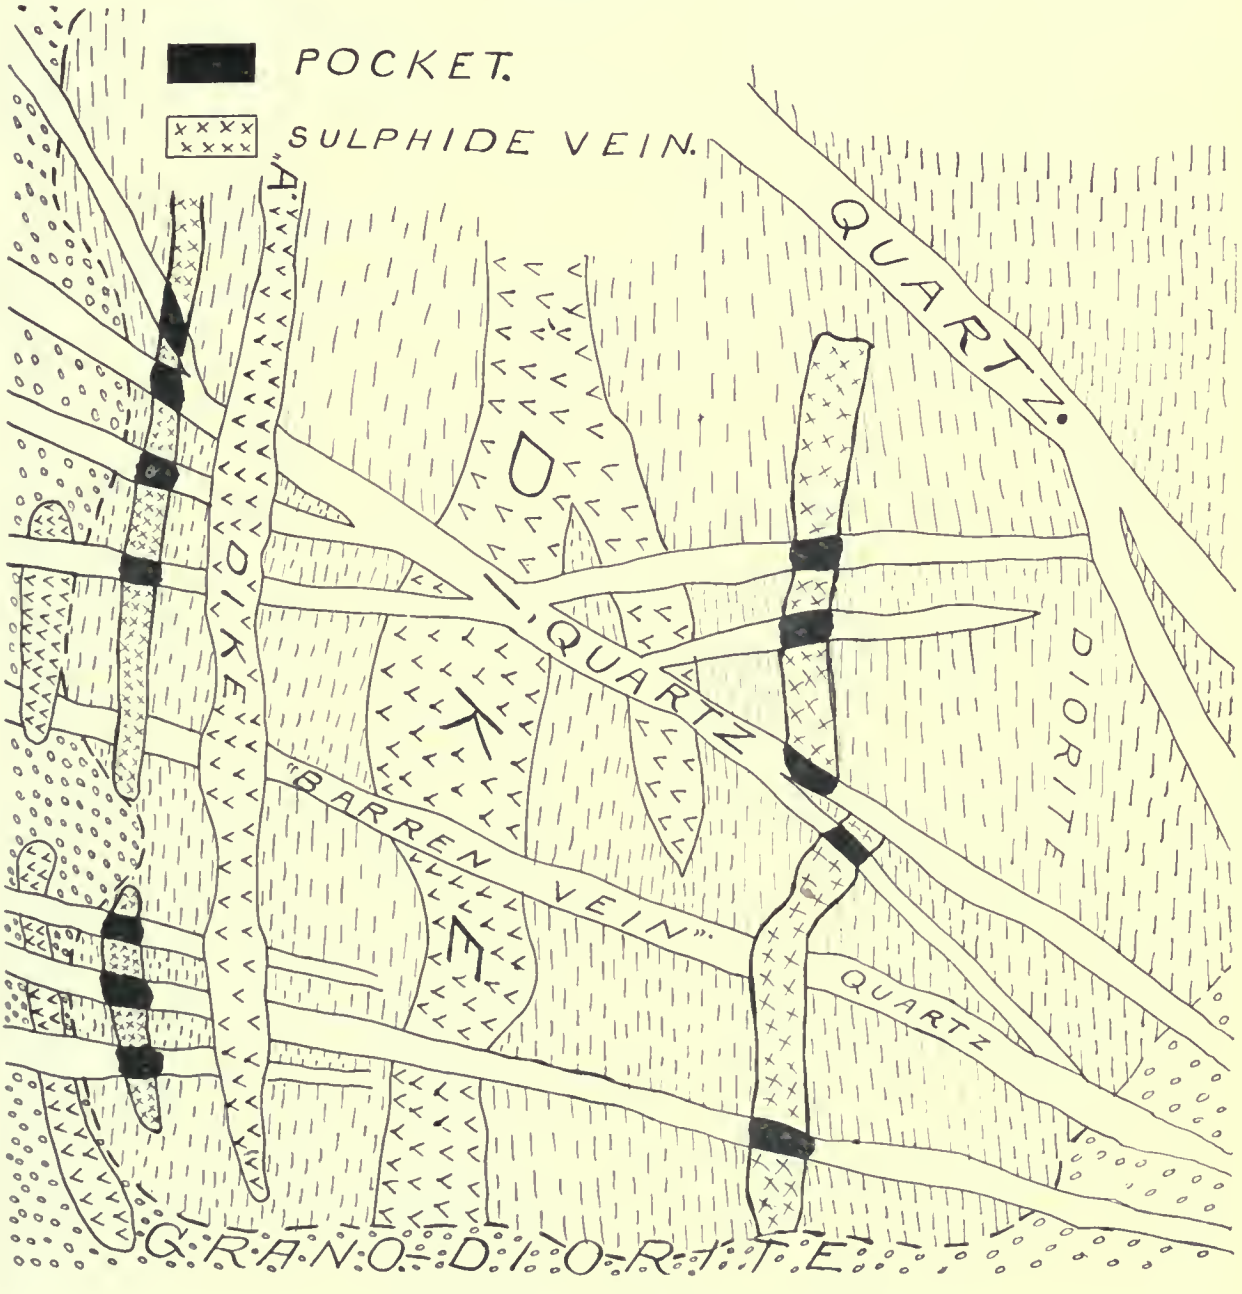
Written for the MINING AND SCIENTIFIC PRESS
By GEORGE W. KIMBLE.

The theory of secondary enrichment has been generally accepted as the process by which the pockets or bonanzas in gold veins have been formed. To support this theory, many persons have written descriptions of occurrences of ore that have been extracted under their management or examined by them. The writer, having been prevailed upon to contribute a description of some of the pockets taken out by him, offers the following in the interests of science, with the hope that others may give their experience in this kind of ore deposits.

The accompanying sketch is a geological plan of about forty acres, covering a strip at the eastern base and a portion of the slope of Mt. Thompson, in Eldorado county, California. The quartz veins and their enclosing rocks are clearly indicated.

The surface soil was of a dark red color and a clayey nature, varying in depth from one to six feet, consisting mainly of angular gravel and small boulders of the underlying bedrock. A large portion of the surface of the hillside and the beds of two ravines within this area had been washed away by the early placer miners, who obtained large quantities of rough or 'seraggy' gold. This gold was intermixed with particles of quartz, accompanied by the rare mineral, roscoelite, all being usually coated with a black or dark-brown oxide of iron.

On the east and north of the tract described there is a large area of grano-diorite, while the greater part included in the sketch is but a small portion of a large area of normal and very much altered diorite, diabase, and porphyrites, traversed by many quartz veins, which vary in size from a fraction of an inch to several feet.



Geological Plan of 40 Acres on Mt. Thompson, California.

At two points on the western edge of the grano-diorite, there is an outcrop of a dike averaging six feet wide, composed of a greenish colored rock, that contains many microscopical crystals of feldspar and hornblende. This dike is much fractured by shrinkage and compression. The porphyrites appear as dikes in the diorite, and have many off-shoots or spurs at various angles with the main dikes.

The diorite in contact with these dikes is altered to a dark-colored bluish micaceous rock, the gradual transition from the normal to the altered rock being discernible at many places. The diorite and the porphyrites are extensively fractured by horizontal, vertical, and dip

joints. The dip of the formation is from 50 to 70° east.

The quartz veins are shown in the sketch. Those that continue as far as the grano-diorite extend into it for a distance proportionate to their size. The strike of the smaller veins is at such an angle with that of the larger ones that they intersect the latter within the diorite and porphyrite area. The larger veins have a uniform dip, about 70° southwest, while the smaller ones dip in the same direction with a dip varying from 40 to 60 degrees.

In the sketch, *A* is a granular feldspathic dike about eight feet wide that must be younger than the quartz veins, as it slightly faults them in their strike where it crosses. There are two sulphide veins within the area that have a strike nearly at right angles to the quartz veins. These sulphide veins are nearly vertical. The small one varies from a fraction of an inch to about four inches; the larger is as much as four feet wide in places. Both veins are thoroughly oxidized from the surface to various depths, the oxidized portions having a black, a dark-brown, or a yellowish color. All the quartz veins except one cross the sulphide veins at their intersection, the latter being faulted from a few inches to 27 ft. at the surface. In the exception noted, the sulphide vein crossed the quartz at their intersection and faulted the latter about one foot at the surface.

The pockets occurred only at the intersection of the sulphide and quartz veins, and only where the latter crossed or cut through the former. In the cases where the sulphide vein crossed the quartz, or where the sulphide did not come into actual contact with the quartz; that is to say, if there was a mere film of any other rock between the quartz and the sulphide, there was no pocket. The pockets varied in value, some containing only a few dollars' worth of gold, others producing thousands of dollars. The quartz was very rich, a candle-box full of specimens yielding a thousand dollars or more. Some of the larger pockets contained chunks of solid gold weighing several pounds. The pockets consisted of gold, roscoelite, tellurides, and iron pyrite in quartz and calcite. The quartz was sometimes transparent and nearly colorless, sometimes amethystine. The larger portion of the gold would be found in the quartz at its intersection with the sulphide vein, the quantity gradually decreasing in all directions. At a distance of a few inches from the centre of the pockets, the quartz became absolutely barren. The smaller quartz veins contained but one pocket in depth, while the larger veins contained several, which were, on an average, about six feet apart on the dip of the vein. In these large veins the portion between the pockets would always yield a good showing of free gold by panning the decomposed material between the walls, notwithstanding the fact that the solid quartz would not yield a trace.

The sulphide veins were largest at the pockets and contained no country rock, nor did they contain any gold except immediately at their contact with a pocket. All the quartz veins gradually pinch out or else split into numerous thread-like stringers as soon as there is no more evidence of oxidation.

Within the area included in the sketch, it was demonstrated that wherever, in the language of the pocket miner, "an iron seam," be it ever so small, "intersected a seam of quartz, there would be a pocket." But it was also demonstrated that it is absolutely necessary, in order to make the pocket, that the quartz "*cut across* the iron seam." In this formation it was evident that there were three sets of fissures, which were of as many different ages. The first was the single fissure now filled with barren quartz. The second were what are now the sulphide veins, which are excellent examples of the replacement type. These second fissures cut across the first one—the single vein mentioned. The third fissures were what are now the quartz veins containing the pockets, which crossed and faulted those of the second period. It is noticeable that the faulting was considerable at what is now the surface and died out below the line of any decomposition.

It is very evident that the larger quartz veins continue much deeper at some distance each way on their strikes from the point where the pockets occurred. It was demonstrated that there were no pockets at the intersection of quartz with quartz. It was my opinion at the time that I worked these pockets, or bonanza deposits, that they were formed by descending, instead of ascending, waters, and that the sulphide veins influenced the deposition of the great masses of gold at their intersection with the quartz veins.

A Remarkable Lease.

The Hayes-Monnette lease on the Mohawk mine at Goldfield expired in January, and Mr. M. J. Monnette told the story of his enterprise to the *Goldfield News*, as follows:

Four million, four hundred thousand dollars is the production. This includes the settlements already made, the fifty carloads now in transit, and the five or six carloads that remain on the dump, and which will be shipped within the next few days. Messrs. Hayes & Monnette are removing the hoist from the property to the Goldfield Columbia, which they will operate on an extensive scale. The lease goes on record as the most profitable of its kind in the history of the world, not only in the amount of wealth it realized for its owners, but for what it did to bring a great mining camp into the prominence it deserved.

This lease does not have the number thirteen figuring in it to any great extent, but it is remarkable that work on it was begun, ore was struck, and work was concluded on a Friday. The four owners, G. H. Hayes, M. J. Monnette, J. W. Smith, and Harry Benedic, are each about $900,000 richer as the result of their venture. Another month, even a week, would have enabled them to pass the five million dollar mark in production, for when the lease expired and the ground reverted to the Mohawk people there was at least one million dollars' worth of ore blocked out and awaiting the breaking and hoisting that could have been so easily accomplished with the splendid equipment of the property under the direction of Superintendent Runnels. The lease was originally 373 by 700 ft.; two-thirds of this area was sold to other lessees, none of which was highly productive.

Mr. Monnette says that the greatest production of the lease in any one day was $60,000, and the highest assay was better than $100,000 per ton. This was exclusive of a selected piece that ran better than a quarter of a million dollars. The greatest production for any one month was $1,300,000 in October. The ore averaged $400 in the car. Nearly all the production was through No. 1 shaft. No fatalities occurred during the life of the lease, the worst accident being the loss of a portion of a finger. For several months an average of 130 miners were employed.

THE recession of the Niagara falls is a matter of recent geological history. It did not begin until after the third great glacial retreat, as the drainage of the Great Lakes had not been through the St. Lawrence previous to that, and the time required for the river to eat out the gorge from Lake Ontario to the present position of the falls, was only about 70,000 years.

Notes on Mexican Mine Labor.

Written for the MINING AND SCIENTIFIC PRESS
By CARL A. ALLEN.

Although there have been few articles on the Mexican laborer recently, they were at one time not infrequent, and those articles and various conversations that I have had with mining men lead me to believe that there has been and yet is a prevailing impression that, while the wages of the Mexican miner are low, still, owing to his alleged lack of industry and mining ability, his work is expensive. Some phrasemaker once said: "Cheap labor means dear work," and this principle, while doubtless true, is too often unthinkingly applied. Cheap labor is expensive, but the question of cheapness is merely a local one. Because an American miner gets $3.50 per day gold and a Mexican gets $2 per day silver, it by no means follows that the Mexican is getting low wages. It is forgotten that one dollar spent in the United States does not mean that it is equal to the expenditure of 4s. 2d. in England, or two *pesos* in Mexico. Two silver dollars in Mexico will buy more of the necessaries of life than one dollar in gold in the United States, although the legal difference is only about two *centavos*. Hence to give a Mexican miner the absolute equivalent of the wages of an American miner would be to overpay him. The fact is that 'cheap,' in the phrase quoted, simply means cheap at the place of production, and in this sense cheap and poor are synonymous.

Depreciation of Mexican labor by American laborers often comes from a misplaced pride of race on the part of the latter, but the Mexican at $1 is a man *far* more to be preferred than the Slav, Pole, or Finn at $3; and, on the whole, as good, if not a better man for the money than the so-called American miner, as he is found today.

On looking into the systems now in vogue of employing the Mexican, we find him usually working on a contract, where he is paid by foot of advance, or by '*cuete*,' as it is called, or else he is being paid by foot of hole drilled; that is speaking of the *barreteros*, or drillers; the *peones* or shovelers, and other unskilled laborers being paid by the day. The object is that of all contracts, namely, to pay only for results obtained, and so far has this contract system been carried out by Americans operating in Mexico that I have even known them to pay so much per set for putting in timbers. This usually works so favorably to the men that, when a new company would commence operations, a man would not ask just for work, but for a contract for anything from bringing in a stray mule to driving a tunnel.

Some of the disadvantages of the *cuele* system are as follows: If the vein is hard, it will be avoided and although apparently not important, the famous old Las Yedras silver mine stands as an example of where the ore (in a wide vein) was entirely lost in some of the lower levels, due to the necessity of paying by *cuete*. The miner will demand the right to point his holes as he wishes, with the result that they will not be placed in a manner to break well, and leave a good floor. Again, by contract, after a short time the work is pretty liable to go slow, it being my experience that generally speaking, more than two Mexicans cannot long work peaceably together, but will quarrel and not hesitate to shirk responsibility for poor work, each on the other. Another disadvantage of letting contracts is one well known to superintendents of leasing mines in the United States, that is, the liability of the contractor to bring in a class of men detrimental to the order of the camp, men that may have been blacklisted by the company itself. Lastly, I would mention a very important fact noted from experience, and that is that a man working by contract and receiving his pay in larger amounts is a poor customer at the company store, but will go off to some near-by town to show the people how prosperous he is, even though prices are higher.

The second method mentioned, or paying by foot of hole drilled, is, to me, far to be preferred; but the following disadvantages are worth considering: The holes will be placed so that they may be hit to the best advantage and where the ground is softest, which may mean that they will break the least ground and the advance of the work will be small for the number of feet or holes drilled. In order for the holes to be properly placed and pointed, the foreman will have to be on hand to see every hole started, or else have a *pobladot*, or blasting boss—a gentleman, usually a Mexican, who by showing partiality and not being around to measure holes when finished, etc., becomes a veritable nuisance.

The second point is, that there is sure to be a segregation of the best men, from the medium and poor *barreteros*, that is, a good man will not work with an ordinary man, but wants the best partner, thus leaving a class of men who, by themselves, cannot do much skillful work, but being good hammersmen, with a good man, would make efficient *barreteros*.

The objection always raised to day's pay is that it is impossible to get the work out of the men. I readily admit that the Mexican will not make as much effort by day's pay as by contract, but I do claim that he will not be contented if his contract rate is not such that by working at the same speed as he would by day's pay, he could earn the amount paid to day's pay men. To illustrate how these conditions work, let me cite the following example: In a certain mine, the men drilling by foot were making three *pesos* per day each, at 25 *centavos* per foot, that is, making an average of 24 ft. per day. In another mine, where the men were working by day's pay, they were drilling 16 ft. of holes for two pesos per day each (all double-hand work), which is the same rate. The day's pay men were putting their holes in *right* and were making very nearly the same footage with a labor bill of eight *pesos*, as their neighbors were on a labor bill of 12 *pesos* daily, both working two shifts; moreover the day's pay men could be changed at any time to any part of the mine at any kind of work, in itself a fact not unimportant.

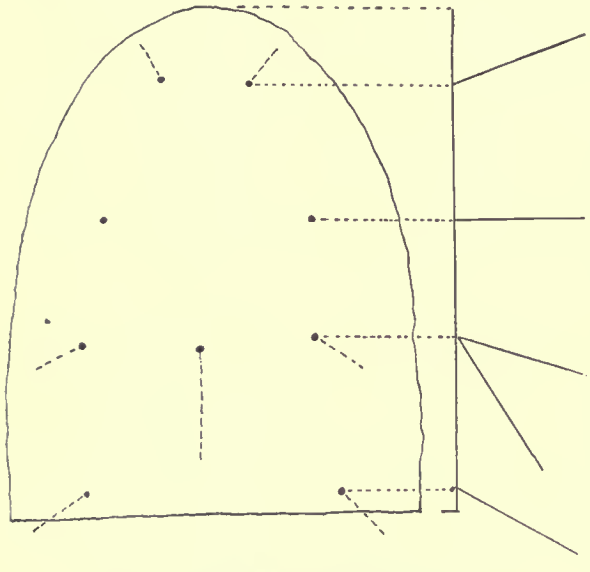
As to how to get the most out of the Mexican when working by the day, I suppose that every man has his own way. Although it requires a great deal of patience, it has been my experience, and also some of the best engineers with whom I have talked in this part of Mexico, that the people as a whole are far more responsive to kind firmness, than to harshness or abuse. In fact, I have never seen any people so amenable to a kind rebuke as the Mexican, as he is found well south from the border.

Having tried to show that, with a little care, the Mexican *barretero* can be worked in most cases to a better advantage as a day's pay man, let us notice an important commercial reason for this method. A good many operators look at the question from the viewpoint that as you don't have to pay much to each Mexican, place all the men in the mine that you possibly can, and get the work done by numbers and not by efficiency. This is not economical, and worse yet, does not serve to educate the men in the business, which is vitally important for the following reason: In the region with which I am most familiar, that is from Fuerte on the west, to Parral on the east, and from Batopilas on the north to San Jose de Gracia on the south, and I also think of many other parts of Mexico, the labor demand will soon become greater than the supply, therefore it is vitally important to train the Mexican so that each man can do more work, and in no way can this be done as well as by day's pay,

and it can be done well that way. The miner can quickly be taught to point his holes right and not be all day charging them, as is often the case now. I have seen the breasts being broken just as square in Mexico as in the States, and with only a few months of experience on the part of the miners.

Now, in closing, let us just look at a few things, comparing the Mexican miner with the American miner. First, there is at the present time less disturbance in the Mexican camps than in those of the United States. The recent trouble at Cananea, I understand from a letter from a man on the ground, was caused by agitators from the States, and although improperly handled Mexicans are very liable to disturbance, properly handled men are inclined to remain orderly. The same thing may be said of the regularity with which the men work, for I have noted that they work nearly as regularly as the miners that I have worked with in Colorado.

The American will be paid $2.50 to $3.50 per day, gold, the Mexican two *pesos*, or 98 cents gold, say $1. Exclud-



Sketch Showing Method of Placing Holes.

ing timbering, a good American miner will not perform more work than two Mexicans, nor as much. He may do it in ground where every advantage may be taken of slips, but, on the other hand, he will certainly not do much more than equal him in rock not especially difficult to break and where the Mexican can be given a general system of placing his holes. For instance, I was driving three drifts 6½ ft. high by 4½ ft. wide at the bottom, in ground hard to drill but very easy to break. After trying several methods of having the holes placed, I finally adopted the method illustrated in the accompanying sketch, which worked advantageously. The men liked it and quickly learned to change the number of holes to suit ordinary changes in the rock, keeping the floor smooth and of proper grade and the breast square. The holes all hit well and in one of the drifts where I kept notes the men were breaking 2¼ to 2½ ft. every round of holes, and when requiring the *barreteros* to clean back from the face they averaged 3½ ft. per day and went some times over four feet in a day where the total labor cost, including the *peon*, was 9.50 *pesos*, or $1.75.

Another advantage is that the Mexican is not paid in cash if, at a little trouble, a store is provided at the mine, and this is necessary, as otherwise the men will be leaving work every few days to go and purchase from other stores, often a day's journey on the trail. Ordinarily the men will take from 75 to 95 per cent of their wages out in goods on which, selling at the usual prices, 50 per cent profit is made. If then he earns $1, he will be paid 25 cents in cash and 75 cents in the shape of 50 cents' worth of goods, that is, he has cost 75 cents for the day, just about one-fourth of what would be paid to an American miner.

For these reasons, I believe the labor condition affords a great advantage to cheap mining in Mexico.

Depth of Death Valley.

The United States Geological Survey has just completed a line of spirit levels through Death Valley, California, and much to the surprise of everyone familiar with the region has ascertained that the depth of that area is not so great as was supposed. The final computations of the results have not yet been made, but the preliminary figures give for the lowest point a depth of 276 ft. below sea-level. Bennett's Well, which is near this point, is 266 ft. below sea-level. These figures may be altered by two or three feet when the final computations are made, but they are probably not more than three feet in error. The Geological Survey now has elevation marks on the highest and lowest points of dry land in the United States.

It is a strange coincidence that these two extremes are both in southern California and only 75 miles apart. Mount Whitney is a foot or two over 14,500 ft. above sea-level, while Death Valley, as above stated, is 276 ft. below. Before the Salton Sink, also in southern California, was flooded by the Colorado river, it contained the lowest point of dry land in the United States, a spot 287 ft. below sea-level.

Previous estimates of the depth of Death Valley based on barometer readings gave for the lowest point figures varying from 250 to 450 ft. below sea-level. The level line of the Geological Survey is believed to be the first accurate determination of elevations in that locality that has ever been made.

LUBRICATION.—The proper lubrication of mine-car wheels and machine parts at a colliery is a most important consideration, and it is probable that few other individual factors so directly affect the cost of production per ton. It is not logical to economize in the various small items of operation and neglect so important an action as the proper lubrication of cars and machinery. One authority claims that about one-half the power expended in mill or mine is lost in overcoming the friction of lubricated surfaces. He also adds that by changing from a poor to good lubricant the loss is cut to one-fourth the power expended. It is impossible to give any fixed rules regulating the selection of a proper oil for mine lubrication; however, it is generally believed that a dark-colored oil is of greater value than one that has been filtered to a red or yellowish color, for the process of filtration is not only expensive, but removes a considerable percentage of the lubricating value. Oil of a free-running nature is best for engine bearings, as it reaches the parts more quickly than oil of a sluggish nature. Where the bearings are open and the oil is applied direct, oil of a eiscid nature is more suitable. The waste incurred in the lubrication of mine cars is hard to avoid when old-fashioned car axles are employed, and this fact makes the buyer hesitate before adopting an expensive oil. Such action is not economy after all, and although some expense is incurred when mine cars are equipped with a self-oiling arrangement, where the oil is supplied from a reservoir in the axle or better still in the web of the wheel, still the eventual saving in power and decrease in wear and waste will more than balance any expenditure.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

The rule as to the sufficieney of a discovery of a placer claim was stated by a Federal Court thus: There must be some gold found within the limits of the land located as a placer gold claim, but it cannot be said in advance as a matter of law how much must be found in order to warrant the court or jury in finding that there was in fact a discovery such as the law requires. The question must be decided, not only with reference to the gold actually found within the limits of the claim located, but also in view of its situation with reference to other lands known to contain valuable deposits of placer gold, and whether its rock and soil formation are such as is usually found where these deposits exist in paying quantities; and, further, in considering the evidence bearing upon the general question, it must not be forgotten that the object of the law in requiring the discovery to precede the location is to insure good faith upon the part of the mineral locator, and to prevent frauds upon the Government by persons attempting to aequire patents to lands not mineral in its character.

Lange *v.* Robinson, 148 Feb. 799.

The statute requires that records of mining claims shall contain such a description of the claim by reference to a natural object or permanent monument as will identify it, and that a location certificate shall contain such a description as shall identify it with reasonable certainty. Under these requirements a description as beginning at a certain stated corner, declaring a parallelogram by courses and distances, and concluded thus: "Corner No. 1 of Wichita Lode joining corner No. 4 of Wichita Eagle Lode." This was held to be a sufficient reference to a permanent monument as would render the certificate *prima facie* competent as evidence of the location. It was also held that a reference to a natural object or permanent monument in such certificate was not conclusive that the law had been complied with, requiring such a reference to natural objects or permanent monuments as will identify the claim; that evidence was admissible that a person could not take the description therein, and, by referring to the natural object or permanent monument therein mentioned find the premises claimed.

Londonderry Min. Co. *v.* United States Gold Mines Co., (Colo.) 88 Pac. 445.

To constitute a discovery which will support the location of a gold-placer claim as against another mineral claimant, it is not necessary that gold should have been found thereon in paying quantities; but there must have been such a discovery of gold as gives reasonable evidence that the ground is valuable for placer mining, considering its character, location, and surroundings. The object of the law in requiring a discovery to precede the location of a mining claim is to insure good faith on the part of the locator and prevent frauds upon the Government.

Lange *v.* Robinson, 148 Fed. 799.

As assignee of an option contract for the purchase of mining claims cannot defeat a recovery of the price for the assignment on the ground of want of consideration, because the contract did not contain a sufficient description of the property, and had expired by its own limitation at the time of the assignment, where such matters appeared on the face of the contract, in the absence of fraud, and where the assignee could observe such defects at the time of the assignment.

Hunner *v.* Mulcahy, (Wash.) 88 Pac. 521.

If the attempted location of a mining claim is invalid on account of the absence of a discovery cut, another person, with knowledge of all the facts, may make a valid location within the limits of the claim attempted to be marked out by the first locator.

Walsh *v.* Henry, (Colo.) 88 Pac. 449.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

A specimen of olivine Basalt was sent by J. W. A., of Los Angeles.

F. W. C., of Jackson, Ore., sends a piece of dark Hornblende-gneiss.

The mineral from W. J. R., Dale, Cal., is micaceous specular Hematite.

The deep blue rock from J. E. R., of Los Angeles, is a dumortierite Schist.

The small specimen of rock from Chico, Cal., sent by C. P. B., is Hornblende-gneiss.

The two samples from Silver City, N. M., marked F. G. C., are: No. 1, Gabbro; No. 2, Diabase.

The supposed radium ore, sent by W. H. W., of Amalie, Cal., is Grossularite, a variety of Garnet.

Specimens from Battle Mountain, Nev., marked B. F. W., are: No. 1, black silicious rock, mainly Jasper; No. 2, altered Feldspar-porphyry; No. 3, altered Granite.

The mineral specimens from Grants Pass, Ore., marked W. G. M., is Quartz, containing the blue phosphate Lazulite and the black oxide of iron and titanium, Ilmenite.

The rocks sent by G. A. D., of Nelson, Nev., are: No. 1, Andesite, or Basalt; No. 2, Andesite; No. 3, Syenite; No. 4, compact silicious rock, mainly Quartz; No. 5, Quartz, with crystals of oxidized Pyrite.

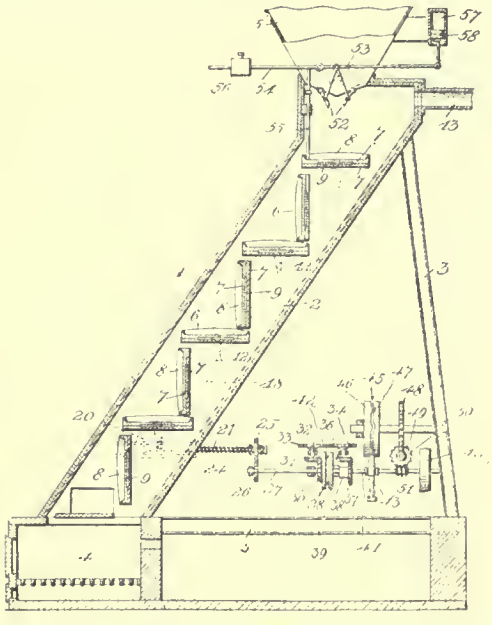
C. A. B., of Eagle, Alaska, sends: No. 1, earthy Limonite and Quartz fragments; No. 2-8, Quartz rock stained with Iron and Copper, due to the alteration of included sulphide. It ought to be assayed for gold.

COPPER EXPORTS AND IMPORTS.—A curious feature of our foreign commerce is found in the fact that, although the United States produces one-half of the world's copper and exports far more than any other country, it is also one of the largest importers of that commodity. The value of copper imported into the United States in 1906 was over $37,000,000, including in this total $6,750,000 worth of copper ore, while we were at the same time exporting over $90,000,000 worth of copper ore, of copper ingots nearly $85,000,000 worth, and of other copper manufactures between four and five million dollars. This anomaly of the greatest copper producing country of the world importing such large quantities of copper grows, apparently, out of the fact that the United States has superior smelting and refining facilities, and that the copper from its immediate neighbors at the north and south—Canada and Mexico—flows to its smelting establishments and refineries. A considerable part of the pig copper imported is brought in for the purpose of extracting the precious metals which it contains, and a part of this comes from European countries. How much of this $37,000,000 worth of copper imported is re-exported under the title of American copper cannot be determined, as any imported article which has undergone a further process of manufacturing after entering the United States is, when exported, reported to the Bureau of Statistics as a domestic manufacture.

MINING AND METALLURGICAL PATENTS.

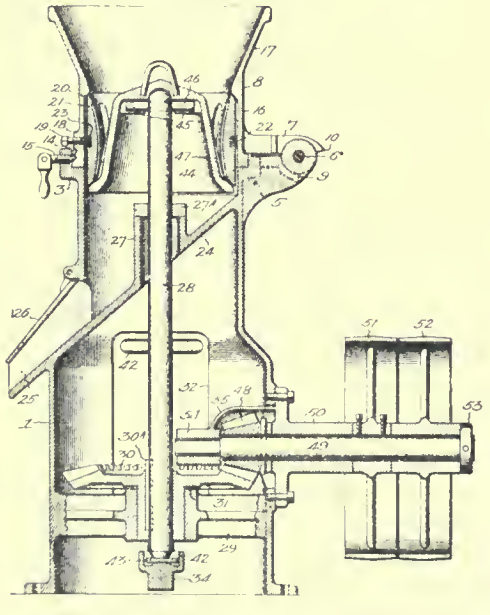
Specially Reported for the MINING AND SCIENTIFIC PRESS.

FURNACE FOR REDUCING CINNABAR ORE.—No. 845,690; Charles F. Burgess, Yreka, California.



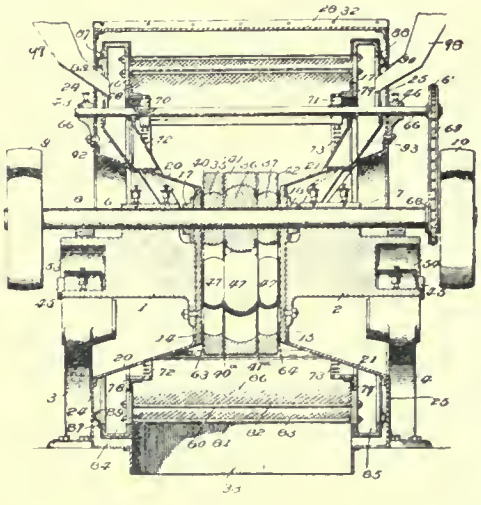
In an apparatus of the character described, the combination with a supporting-frame, of an inclined chute arranged in said frame, said chute being lined with non-heat-conducting material, an intermittently discharging hopper arranged at the upper end of said chute, a series of pivoted ore-receiving leaves arranged one above the other in said chute, means to tilt said leaves with an intermittent movement, and a heating-furnace arranged at the lower end of said chute.

ORE-CRUSHING AND GRINDING-MILL. — No. 845,067; Augustus L. Engelbach, Denver, Colorado.



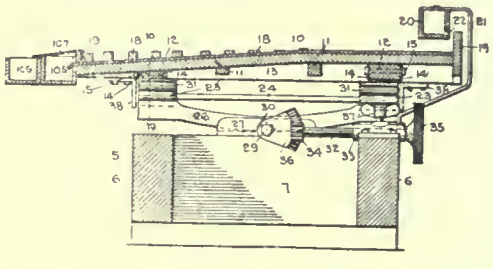
In an ore-crushing mill, the combination with the supporting-frame, of a hopper pivotally hinged to said frame, means for clamping said hopper to said frame, said hopper having a cylindrical aperture extending into its bottom a predetermined distance, said hopper being provided with an outward-flaring hopper aperture in its top intersecting said cylindrical aperture, an inwardly curved lip connecting the lower edge of said flaring hopper's bore and said cylindrical bore, a cylindrical die-ring of chilled or other suitable ore-crushing metal fitting said cylindrical bore, and provided with an upper curved edge fitting the curved lip of said die-ring, a band of soft metal encircling said die-ring, provided with a plurality of tapering V-shaped holes spaced at equal distances apart, and pointed set-screws threaded through the shell of said hopper, and positioned to bear against the upper side of said V-shaped apertures in said soft band, and hold said die-ring up against the curved lip of said hopper, with an upward clamping pressure.

GRINDING OR PULVERIZING-MILL.—No. 845,661; William S. Osborne, Marietta, Pennsylvania.



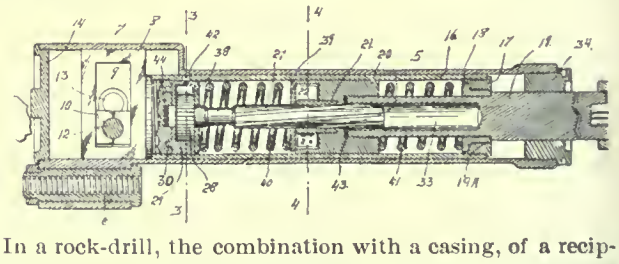
In a pulverizing-mill, a series of independent revolving rings, in combination with a series of rolls located within and imparting rotary movement to said rings, and a series of spring-mounted grinding-rolls also coacting with said rings, the rolls being of different sizes whereby a gradual reduction is attained.

ORE-CONCENTRATOR.—No. 845,449, Michael Christmann, Leadville, Colorado.



In combination a stationary frame, a concentration-deck mounted thereon, said deck having a level portion extending from end to end thereof, and a portion inclining laterally from said level portion, riffles arranged diagonally on said inclined portion, a space being left between the rear ends of the riffles and the end of the deck, a trough located along the side edge of said inclined portion, means for spraying water on the outer edge of the level portion, means for feeding the material at the upper end of said level portion, means for reciprocating said deck and means for inclining said deck transversely.

ROCK-DRILL.— No. 844,582; Henry Deitz, Denver, Colorado.



In a rock-drill, the combination with a casing, of a reciprocable yoke located therein, a hollow member connected to move with the yoke, a piston located in the hollow member, a drill-holder connected with the piston, a loose collar surrounding the drill-holder, the latter having a stop to limit the forward movement of the collar thereon, the hollow member also having a stop for the loose collar forward of the latter, a rifle-bar and ratchet carried by the hollow member and connected with the drill-holder for rotating the latter, and a yielding connection between the drill-holder piston and the hollow member.

Yerington, Nevada.

(STAFF CORRESPONDENCE.)

The mining camp of Yerington is in Mason valley, on the Walker river, 14 miles southerly from Wabuska station on the Southern Pacific railroad. At this point the valley is 4 to 5 miles wide, very fertile and much of it under irrigation. Flanking the valley on the east is the Walker range, which separates the Walker Lake basin from Mason valley; on the west is a low range of mountains, trending north-south, between Mason and Smith valleys. In the latter range, to the west of Yerington, are various copper properties, among which are the Western Nevada, owned by Samuel Newhouse and associates; the Mason Valley mine, owned by Geo. E. Gunn and associates; the Bluestone, belonging to J. R. De Lamar and associates; the Yerington Malachite, controlled by the National Exploration Co., of which Willard Snyder is manager; the Nevada-Douglas, controlled by J. D. Wood, W. V. Rice, Arthur L. Pearse, W. C. Orem and others; the Ludwig, recently sold to Frank J. Hagenbarth and others who are likewise interested in the Nevada-Douglas; the Nevada-Bonanza, controlled by Salt Lake parties and in charge of Jos. A. Harris; the Yerington Ironsides, backed by A. Hanauer, W. H. Tibbals, F. A. Flindt, C. D. Rooklidge and others of Salt Lake. The properties above are named in their order from south to north, making a chain seven or eight miles long. The Western Nevada (formerly the Dyer), Mason Valley, Bluestone, and Ludwig were operated over thirty years ago. Some of their high-grade copper ores were hauled to Virginia City, where they were used in the amalgamating plants as bluestone.

The main body of the range, comprising this district, is granite and porphyry, with bodies of limestone and lime-shale occurring at various points, and ranging from 100 ft. to one mile in extent. The mineralization occurs within the lime and along the contacts of lime, porphyry, and granite. Within the mineralized area is a garnetized lime, impregnated with copper, along a series of fissures; there is also ore in white limestone, the ore occurring in chambers. The outcrop in places is in the form of a gossan and in others a decomposed limestone impregnated with limonite. In other places the lime-shales are garnetized. The main hill comprising part of the Nevada-Douglas holdings is cut by fissures, traceable for over 3,000 ft. A series of cross-fissures occurs, broadening the mineralized area to a width of 600 or 700 ft. The great bodies of ore in this hill, as demonstrated by development, consist mostly of copper carbonates in a garnetized lime. The average of these ores is said to be 3½% copper. The first development was in the shape of adits, pits, and open-cuts. More recently an adit was started at a point near the base of the hill, on the Smith valley side, which, when driven 2,500 ft., will have 600 ft. of depth. This adit has progressed 300 ft. Electric wires are being strung from Como to the portal of this adit to supply power for the compressor and pumps. A vertical shaft is being sunk at this point to reach water-level and to get into the sulphide ore. The main camp, and possibly reduction works, will be situated on the Smith valley side. W. C. Orem is manager; J. W. Smith, superintendent, and S. S. Arentz, local manager.

The Ludwig adjoins the Nevada-Douglas on the north and has the deepest working in the district, an incline shaft having reached a depth of 600 ft., giving a vertical depth of 500 ft. Besides the development extending from this incline, there is a large amount of surface work. Practically all the ore taken out and exposed by these workings is carbonates and oxides, excepting at the bottom of the shaft where sulphides have been reached at water-level. The recent sale of this property was negotiated by Max. Junghandel, of Yerington. It is understood that in the future the management of the Ludwig and that of the Nevada-Douglas will be closely allied.——The Bluestone, managed by C. A. Week, is on the east slope of the range, facing Yerington. This property is perhaps the most thoroughly developed of any in the district. The main working level is 300 ft. below the apex of the orebody and reaches a depth of 650 ft. on the incline. The ores here are likewise in the limestone and about 100 ft. away from its contact with the granite. There is a low percentage of carbonates and oxides in this property, the bulk of the ores being sulphides, comprising chalcopyrite, with a little bornite, of medium and low grade. Plans are being considered for a reduction plant of 1,000 tons daily capacity. An experimental plant has been operated, which roasts to magnetize the pyrite and then passes them through a magnetic separator to eliminate a large part of the gangue, thus making a high-grade smelting concentrate. It is quite possible that a large plant will be erected to operate along these lines.——The Spragg mine, now owned by the Mason Valley Mines Co., lies just south of the Bluestone and comprises 156 acres. The work here is in charge of J. W. Logan. The orebodies are in the limestone, and at the contact of limestone with porphyry and rhyolite. The ore occurs in a garnetiferous limestone and consists of carbonate in the upper working and sulphides at greater depth. In the lower workings is chalcopyrite, running from 4 to 27% copper. The deepest adit cut the sulphide ore 454 ft. from the portal; at 604 ft. in a cross-cut the work is still in ore. This adit is 275 ft. deep and a depth of 400 ft. below the apex will be reached. Work will be directed to blocking out ore. Since Mr. Gunn began, 900 ft. of work has been done. This property shipped, a few years ago, 1,600 tons of carbonate ore that averaged 32% copper. The altitude of this property and the Bluestone is about 5,000 ft.——The Nevada Consolidated, in the same locality, has been opened to some extent. It is in the hands of the same parties as control the Nevada-Douglas.——The Western Nevada group occupies a portion of the southern end of the same limestone area on which the Bluestone and Mason Valley groups are situated. This is the old Dyer mine which was developed a number of years ago. Adits and pits expose carbonate ore at many points on the hill occupied by this group. A camp is being established here and a new adit is being driven for greater depth. H. C. Bowdich represents Samuel Newhouse here.——The McConnell mine adjoins this property on the north. It was developed years ago and some shipments were made. A small tonnage of ore remains on the dumps as the result of former operations. Chas. W. Lane, of California, controlled the McConnell in the early days.——The Yerington-Ironsides group is on limestone at the north end of the series. It is seven miles northwest from Yerington. This group is being developed under the direction of Fred Flindt.——The Yerington Central group, situated north of the Ludwig, is managed by J. J. Beatty, of Michigan, with H. D. Trenam in charge. A 600-ft. shaft will be sunk as rapidly as possible.——The Empire Nevada M. & S. Co., controlled by Wm. Gelder & Co., of New York, has acquired an area extending from near Walker river westerly toward the foothills, including low hills and a flat. The holdings include an old smelter near the river. A large number of open-cuts, pits, and adits on this ground show a fair grade of copper carbonate, silicate and some pyrite in a porphyritic gangue. Tests are being made to ascertain the adaptability of the ore to leaching.——The Yerington Copper Co. is developing a group of claims four miles east of town in the Walker range. A porphyry dike runs east and west through this granite range. A vein four to six feet wide strikes longitudinally through the porphyry dike and to a large extent the ore extends into the dike material. The gangue is a quartz-porphyry and the ore comprises copper carbonates, oxides, and chalcopyrite. Adits are being run on the vein at various levels and a shaft has been started at the portal of the lowest adit and the intention is to sink 1,000 ft. Gasoline power has been installed for hoisting and air-compressor work. C. D. Rooklidge, of Utah, is manager for the company.——The Blue Jay is situated on a mineralized zone that runs parallel to the Yerington. It is considerably developed and has a good showing of copper ore. Hamlin & Silvers, of Reno, have a showing parallel to the Yerington, which they are developing.

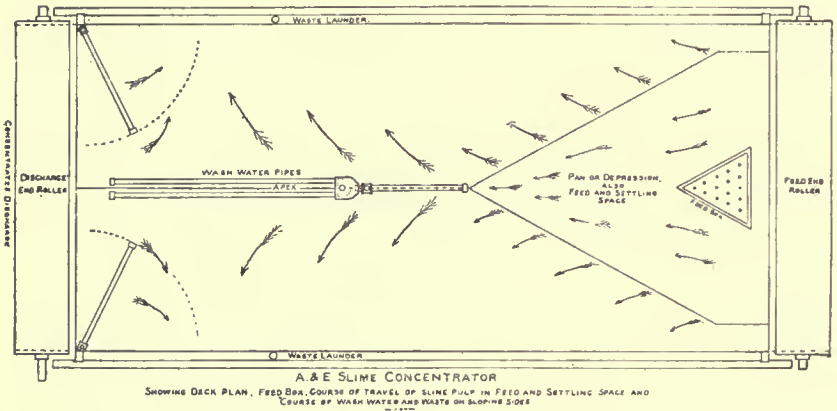
THE BUCYRUS CO., of South Milwaukee, Wis., is building 63 steam-shovels, three railway-cranes, and one railroad pile-driver for work at Panama. These comprise all of the steam-shovels, railway-cranes, and railroad pile-drivers purchased by the Isthmian Canal Commission to this date.

The A. & E. Slime Concentrator.

The great need of a concentrator that will save the maximum amount of slime in a concentrating plant, and at the same time be simple in construction and easy of operation, has always been recognized by mill operators. The accompanying illustration shows such a machine. It is claimed that in its design and construction are embodied features differing widely from anything heretofore introduced in concentrators of this class. It is the joint invention of Randall P. Akins and James P. Evans, both of whom have been for a long time connected with the Colorado Iron Works Co., and are well known as experienced mill builders.

This concentrator was developed and perfected by the inventors in an ore-testing plant; hence, it has been carefully tried as to its efficiency in operation and the saving of the minerals passing over it. For nearly a year past, since the machine assumed its present form, it has been subjected to almost continuous work on all classes of concentrating ores. Therefore, it is now offered with the assurance that the experimental element has been eliminated and that it will accomplish all that is claimed for it under regular conditions of operation.

The machine is of the traveling-belt type, with a longitudinal or endwise-shake. It is provided with a roller or drum at each end, also a wash-roller and a take-up roller below the deck. These rollers serve the purpose of carrying the belt, imparting the travel, washing, taking up, and adjusting the movement of the belt. These operating features are in a measure similar to those of a Frue vanner, but there the similarity with that and other machines ends. The great advantage of the machine lies in the form of its deck, as will be understood from an examination of the outline drawing. The triangle shown is the pan or depression and the feed and settling space, the forward lines of which are substantially level; the central line extending from the settling space to the discharge end of the machine is the apex, and is the high line or portion of the deck from which the deck slopes forward and sidewise to the waste launders on each side in a general direction shown by arrows. The belt is preferably of canvas or duck and of sufficient flexibility that in passing over the deck it conforms to the contour thereof, maintaining the form of depression into which the slime pulp is distributed from the feed-box. The water in the pan becomes quiet and the mineral constantly has an opportunity to settle, aided by the gentle reciprocal end shake, and adheres firmly to the surface of the belt. The pan or depression is so shaped that as the heavy mineral settles the lighter material is thrown by the motion of the table and gradually drawn by the belt toward the discharge point of triangular feed and settling space so that the tendency is for the lighter material to come on the deck proper at the beginning of the apex, where it is gradually washed toward the sides by a series of jets of water from a longitudinal and horizontal perforated pipe about 20 in. long, placed immediately above the deck at the beginning of the apex. Following this pipe along the apex is a similar one extending to the discharge end that supplies wash-water to the deck.



A. & E. Slime Concentrator
Showing Deck Plan, Feed Box, Course of Travel of Slime Pulp in Feed and Settling Space and Course of Wash Water and Waste on Sloping Sides
Manufactured by Colorado Iron Works Co. Denver Colo
Patents Pending.

Two independent wash-water pipes are placed near the two corners at the discharge end, which have an adjustable sweep for further cleaning the concentrates when necessary. The overflow from the feed and settling space is uniform and thin, as is also the flow over the sloping sides of the machine with the added wash-water, which gives the maximum opportunity to settle any agitated mineral that may be traveling with the gangue toward the waste-launders. The concentrates are carried over the end of the machine by the travel of the belt, which, passing under the wash-roller below the deck in water in the concentrates box, are washed off by the reciprocal motion of the table, aided if necessary by jets of water supplied through a perforated pipe playing on the belt as it comes out of the water.

The mechanical features of the machine are simple, easily assembled and cared for when in operation. The deck or top is supported by six flat oak or hickory legs, four inches wide and one-quarter inch thick at thinnest part. These legs are amply strong, and while supporting the top and preventing any side sway, are sufficiently flexible to allow of an easy reciprocal motion to the top. The main drive-shaft is placed at the head or feed end, and is fitted with cranks on each side, from which lead two side rods, which in turn are attached to the deck near supports under the head end and which impart the reciprocal motion or end shake. On the drive-shaft are tight and loose pulleys to receive the drive from the mill-shaft. The tight pulley is cast heavy and also serves as a balance wheel, giving steadiness to the motion of the table. A four-step cone pulley on this shaft is belted to a similar one on a counter-shaft on the supporting frame. A pair of bevel gears engages and transmits the power from the counter-shaft through the long side-shaft to the discharge end of the table, where, by means of cut gears that allow for the motion of the table, it is communicated to the roller at the discharge end by a worm and worm-wheel, which in its turn imparts the travel to the concentrator belt, the speed being adjusted by shifting the belt on the cone pulleys. The travel of the belt is approximately 26, 33, 43, and 56 in., respectively, per minute, as governed by these step-cone pulleys, at a speed of 225 rev. per min. of the drive-shaft. The drive-shaft can be run up to 250 rev. per min., however, without disadvantage, and on some ores to advantage.

Ample means are provided for adjusting the belt so that it will run true and also for taking up the stretch. The wearing parts are few and the belt will last a long time, and, with ordinary care, the machine cannot get out of order.

The floor space occupied is 7 by 16 ft., or about the same as any standard concentrator and less than one horse-power is required for operation.

The weight of the machine, boxed and ready for shipment, is about 3,000 lb. The price is $450. It is manufactured by the Colorado Iron Works Co. of Denver.

Trade Treatises.

The Denver Fire Clay Co. has issued its Bulletin No. 24, calling attention to the crucibles, scorifiers, and muffles made by the firm, and to the Case gasoline furnace.

Buff & Buff, the wellknown instrument makers, of Boston, issue a catalogue of their latest engineering, surveying, and mining instruments. It is handsomely illustrated.

The Rapid-Economy Stamp-Mill Co. has sent us a copy of their new and attractive folder, describing the Rapid-Economy mill. The publication is well illustrated, including photographs of all parts of the mill. The company states that this mill has greater capacity, consumes less power, costs less for repairs per tonnage crushed, and saves a higher percentage than any other stamp-mill.

Editorial.

AMERICAN mining engineers visiting London can obtain copies of this journal from Leathwait & Simmons at 5 Birchin Lane.

UNDER 'Market Reports' we publish each week the daily average prices of copper, lead, spelter, and silver at New York. Those who buy or sell ore will find them trustworthy. To our subscribers in San Francisco we can give the quotations by telephone.

WE WELCOME the first issue of *The Canadian Mining Journal*, a new fortnightly paper that is the successor of *The Canadian Mining Review*, a monthly journal, which for twenty-three years has occupied an authoritative position. We wish our contemporary every success.

THE PRESENT prosperity is viewed with timidity by many men who are well informed. The fact is, the whole world is out-running its credit. Much of it has been devoted to real development, but undoubtedly much of it also has been squandered on paper enterprises, whose failure is imminent. The banks of New York have been skating on thin ice in the effort to support the stock market. A serious collapse is probable as soon as the exhaustion of capital becomes evident.

THE other day at Goldfield there was a meeting of "millionaires and others," so says an Associated Press dispatch. It was held at midnight, hence the disreputable character of the crowd. The "others" were really respectable people, despite their temporary association, for which they would doubtless be ready to apologize. The fact is, the Nevada camps are making millionaires so rapidly, according to the *Daily Scream*, that the plutocrats of the mines are becoming common, not to say vulgar. Wealth has almost ceased to be a distinction at Goldfield; soon the millionaires will be undistinguishable from the "and others." Not to be a millionaire will be regarded as a pose.

SECONDARY ENRICHMENT in copper lodes has been so thoroughly demonstrated to be a factor in their economic value that any mining engineer who appraises copper mines without considering this matter, is doing an injustice to his client. We learn that the bottom workings of an important mine in Placer county, California, exhibit the lower limit of a zone of secondary enrichment, the high-grade secondary copper pyrite in iron pyrite being succeeded by an original ore, poor in copper and highly silicious. Because secondary enrichment, with deposition of chalcocite, extends to over 2,000 feet in certain mines at Butte, it must not be expected that Nature will be as generous elsewhere. At Butte three or four successive periods of

fracturing and thermal activity, at intervals, have produced conditions extraordinarily favorable to the resolution and re-precipitation of copper in lodes of remarkable width and number.

Standardization.

THE Institution of Mining and Metallurgy, an organization of professional men that has won an authoritative position, has recommended the adoption of certain definitions, namely:

1. That the 'ton' be a weight of 2,000 lb. avoirdupois.
2. That the 'miner's inch' be a flow of 1.5 cubic feet per minute.
3. That the 'gallon' be the gallon of 10 pounds.
4. That all temperatures be expressed in degrees Centigrade.
5. That gold and silver returns be stated in terms of fine metal, and not as 'bullion.'
6. That the gold contents of ore be expressed in the Troy ounce of fine gold, worth $20.67 or 85 shillings.

All of these recommendations will, we believe, receive the endorsement of the profession. It will be a great boon to technology if the complexity and confusion due to discordant units of measurement and weight are eliminated by an agreement to use one of each kind. The choice made exhibits much good sense, and it is due to the fact that the committee is composed of English and American engineers of wide experience in such matters. Think of the joy of getting rid of the 'hundredweights,' 'quarters,' and 'stones' of an obsolete English system; consider the advantage of retiring the multitudinous kinds of 'miner's inch' that do duty in different American States; and imagine the satisfaction of knowing the quality of the metal produced in a mill, instead of talking in terms of an uncertain 'bullion,' that may be half impurity for all that the term conveys. And on the top of its excellent recommendations, the committee on standardization asks for further suggestions as to weights and measures. We venture to make one, having learned by experience the necessity for it. Everyone knows the lax manner in which Mexican currency is treated; a report says that a mine in Mexico produces ore worth 20 dollars per ton or that the cost is $10 per ton. It is often left to the reader to guess whether the reference is to American or Mexican dollars. Of course, the sign 'U. S.' or 'Mex.' may be added, but this is clumsy and is apt to be omitted. The present writer has found repeatedly that in notes gathered in Mexico he has set down that something cost $3.50 or $7.80, and in reading such notes long afterward he has wondered which it was, Mexican or American currency, for both are used interchangeably, and the reports of some companies are given partly in one and partly in the other. There is no need for the confusion. We have the *peso* and the *centavo*. Let dollars be the American unit, *peso* be the Mexican; and then if anyone desires to convert either into terms of the other, he can do so by referring to the exchange as recorded at the time in question. When the reference is to the money value of any thing in Mexico, let us use *peso* and *centavo*. This is a suggestion that we made a year ago; the experience of another twelve months has strengthened our belief that it ought to be adopted.

Labor Unrest.

AT Bisbee, at Butte, and at Goldfield there are strikes or lock-outs, and in other mining centres there are signs of trouble. In Arizona the Western Federation of Miners is trying to control the labor unions of the Warren district and the question is simply whether Bisbee is to be an 'open' or 'closed' mining camp. A year ago the miners in mass meeting voted in the proportion of five to one against affiliation with the Western Federation. Since then there has been a uniform raise in wages, the management of the Copper Queen and other companies recognizing frankly that the cost of living has risen throughout the country and that as the price of the metal extracted from the ore has risen to a corresponding degree, it is only fair that the men's wages should also be increased. Although a large proportion of the workingmen at Bisbee do not belong to any union, there has been no discrimination on the part of the management against those that were known to be union men. There have been no labor outbreaks, because Mr. James Douglas and his staff are humane and sensible, a combination not always characteristic of the employers of labor. There should be no room for the unintelligent methods of the Western Federation at Bisbee. At Butte a strike in the newspaper offices threatened to embroil the whole community, for Butte has always been a smouldering volcano of labor tyranny. Although wages were voluntarily raised by the mining companies only last November, from $3.50 to $3.75 per day, the miners recently voted for another advance in order to meet the increased cost of living due to the demands of the smaller labor unions—in other words, the bakers, the butchers, and the tailors have made life at Butte too expensive even for the highest paid mining laborer in the world. After all, it is the difference between income and outgo that represents the saving of the workingman and in this respect the high-priced camps are greatly over-rated. The labor unions, when they are too exacting, occasionally make life hard for their own people. The rate of wages does not measure a man's comfort. At Goldfield, there has been agitation due to the attempt of one labor organization to impose itself on the others, and the community is in danger of a vendetta between two factions. Here the situation is embittered by the presence of some of the people that took part in the Cripple Creek troubles and the legacy of hate from a bygone terrorism threatens to interrupt the working of mines recently made famous by their productiveness. There is this to be said, that any widespread strike now would be folly, for it would precipitate a depression that is surely coming, that will be accompanied by the withdrawal of capital from new enterprises, and the general retraction of industrial activities. The laboring man will do well to make the most of the present era of high wages and the captain of industry will be wise if he makes effective use of the capital now at his disposal. A quarrel between them at this time will be greatly to the disadvantage of both.

By the Way.

Concerning the great break in the Colorado river, fully described in our issue of October 20, the *Engineering News* says:

The necessity for holding the Colorado in its old channel with absolute certainty has now been shown by a great object-lesson. It is apparent that this necessity will increase from now on with the rapid influx of settlers to the Imperial Valley. Every farm and home there is dependent on the strength of the banks by which the river is held in check, just as surely as every house and hamlet in the Holland polders is dependent upon the strength of the dikes. Now that the river is restored to its old channel, there should be no engineering difficulty in holding it there with certainty, and in giving perfect safety to those in the valley below.

We have said there is no engineering difficulty. There are other difficulties, however, of a most serious sort. The work of closing the break has been done by the Southern Pacific Co. That railway corporation responded most nobly to the appeal of President Roosevelt. It was absolutely the only organization that was able to do the work in time, and time, as shown above, was the all-important element. Unless the closure was effected at once, it could not be effected at all. No other organization, great or small, not even the United States Government itself, had the Executive been given unlimited powers by Congress, could possibly have brought together the men and tools and materials in time to save the day.

But now that the emergency has been met and there is time to look to the future, the railway company which has so honorably met the call of public duty ought to be relieved of further responsibilities. When the question is asked where the responsibility should now be placed for the permanent control of the Colorado river, it is difficult to find any other reasonable course than for the United States to take charge. That no private irrigation company, organized for business and profit, could well be trusted with such great responsibility, should be clear anyway, and has certainly been demonstrated with absolute conclusiveness by the events of the past three years in this region.

It may be suggested that the States could assume control; but part of the land to be protected lies in California, part in Arizona, and a considerable part, including the whole lower course of the Colorado where breaks must be guarded against, is in the Republic of Mexico. Thus the protection of a large area of United States territory from inundation depends on the control of a river channel in Mexico.

We can see no satisfactory solution of this difficult problem except the purchase from Mexico of this territory and its annexation to the United States. At present this country is in the anomalous position of having a great valley of enormous potential value which is likely at any time to be flooded and destroyed for all time by a river on foreign territory overflowing its banks. Mexico, on the other hand, has either to control the river herself, to protect her neighbor, or admit foreign forces to her soil to do the work.

The whole situation is so likely to lead to international complications that there should be no difficulty in arranging a satisfactory treaty of annexation. Conceivably, Mexico may desire to retain a narrow strip at the very mouth of the Colorado to give her access by land to her territory in Lower California; but this might possibly be met by purchasing the whole lower peninsula. While this has little value, save possibly for mineral deposits, yet unknown, its possession would place under United States jurisdiction a region commonly reputed to be a resort for fugitives from justice.

A word should be said regarding the unprecedented methods adopted to close the *crevasse*. The problem was one never before presented, so far as we are aware, in all the annals of engineering. Here is a great river, subject to extreme and sudden variations of flow, from 2,000 to 100,000 cu. ft. per second. Its whole volume is flowing through a *crevasse* in its banks some 2,000 ft. in width, and the whole region is one mass of silt and mud, no solid foundation anywhere. Worst of all, the time to effect closure is extremely limited. There is no time to make elaborate plans, and little time even to consult as what is to be done.

Under such circumstances it would be ungracious to criticize what was done or not done. It appears to be clear that the early attempts at closure were a failure largely because the magnitude of the task in hand was not appreciated, and also because the funds and forces available were inadequate for the work. Of the later efforts, when the whole strength of the Southern Pacific organization was concentrated on this work, the plan of work in which the wooden gate was constructed appeals to an engineer as sound and well schemed. The plan would undoubtedly have been carried to success had not the drift carried down by the flood lodged against the gate and obstructed the passage of water through it.

The method by which successful closure of the breach was finally effected consisted, as already recorded, of carrying pile trestles across the *crevasse* and dumping rock as rapidly as possible from these trestles, thus making a rock-fill dam across the channel. Had any considerable height been attempted with these dams, the scour would doubtless have concentrated at some point and undermined the trestle; but by making successive lines of parallel trestles and dams, the fall at each was kept within moderate limits and the structure remained in place.

This simple plan of operation, while it presented many possibilities of failure, offered the great advantage of doing the work with railroad machinery and railroad methods, and therefore of rapidly effecting results. We can conceive of no other method by which an effective barrier could have been constructed across the *crevasse* in the limited time available. It will be apparent also, that, had it not been for the branch line built last summer to the site of the break from the main line of the Southern Pacific Co., it would have been impossible to have assembled the men, material, and supplies necessary to effect the closure of the break by this or any other method of operation.

In discussing this subject a month ago, when the possibility of closing the breach was still a matter of grave doubt, we said that Congress ought to act immediately on the President's appeal for funds. Now that the Southern Pacific Co. has gone forward and completed successfully the task, relying on the honor of the Nation to reimburse it for its expenditure, we say with renewed emphasis that Congress ought to act promptly and justly in this matter. Doubtless, corporations have no souls, and this particular one has been frequently accused of lacking all moral principle in addition. In the present case, however, it has shown something of the same honorable quality that impels a man to risk his own life or property to check a conflagration when no one else is at hand to act. The Southern Pacific Co. is entitled to fair and liberal recompense at the hands of the Nation for the great service it has performed, and it would be a proper thing also to recognize in some appropriate way the efficient services of the leaders in the field who have finally won a great victory after the discouragement of repeated defeats.

Personal.

W. MURDOCH WILEY is at Guanajuato, Mexico.

ARTHUR R. TOWNSEND is at Telluride, Colorado.

THEO. F. VAN WAGENEN is at Zacatecas, Mexico.

W. LAWRENCE AUSTIN was in San Francisco recently.

C. M. FUELLER has returned to Denver from Mexico City.

CLAUDE V. HAINES has left London to proceed to Spain.

STEWART TOD is visiting New York from Batopilas, Mexico.

R. DE H. ST. STEPHENS has returned from Russia to London.

W. B. KEHOE, formerly of Ouray, Colo., is now at Barstow, California.

A. B. CARPENTER, of Carpenter & Brennon, Mexico City, is at Los Angeles.

E. D. MCDERMOTT is at La Estrella copper mine, near Guadix, in Spain.

JOHN A. REID, of Stockton, is examining mines near Keeler, California.

J. S. CARNAHAN is manager of the San Pablo mine, at Monterey, Mexico.

ROBERT S. LEWIS is engineer with the Warrior Copper Co. at Globe, Arizona.

J. B. FLEMING is now with the Joshua Hendy Iron Works, San Francisco.

M. S. WALKER is with the Southern Cross Gold Mining Co., at Cable, Montana.

J. B. PITCHFORD has been visiting the copper mines of Shasta county, California.

F. LYNWOOD GARRISON is in Santo Domingo. He will proceed from there to Mexico.

G. D. LOUDERBACK is now associate professor of geology in the University of California.

E. W. SEBBEN, of Denver, left this week for Utah, where he has some examinations to make.

GEORGE I. BENTLEY is manager for La Ventura Mining Co., at Oeotlan, in Oaxaca, Mexico.

J. V. N. DORR, of Lead City, South Dakota, has opened an office in the Bank Bdg., at Denver.

COURTENAY DE KALB left Los Angeles on March 21, on a visit to New York and Philadelphia.

J. MALCOLM MACLAREN is expected in San Francisco on his way from New Zealand to London.

D. H. BRADLEY, JR., is directing the operations of the Parral Con. Mines Co., in Chihuahua.

ERLE HUNTLEY has been appointed manager for the Zinc Corporation at Broken Hill, Australia.

JAMES ASKELL is general manager for the Santa Rita Mining Co., at Sombrerete, in Zacatecas, Mexico.

F. G. OLENDORF is general manager for the Azteeas Mineral Co., in the Aleeron district of Guerrero, Mexico.

W. J. FARRAGUT has been appointed assistant to the manager of the Dolores mine, in Chihuahua, Mexico.

FRANK E. SHEPARD, president of the Denver Engineering Works Co., has returned to Denver from the East.

J. RODNEY BROWN has been appointed superintendent of the cyanide plant of the Peregrina mill at Guanajuato, Mexico.

CHARLES W. HOWBERT, formerly of Cripple Creek, is now manager of the Cienguita Copper Co., in Sonora, Mexico.

HAROLD I. BROSIUS has accepted the position of assayer and chemist with the Imperial Gold M. & M. Co. at Apex, Colorado.

J. M. CAMERON has left Goldfield, and has accepted the position of manager for the Butte Central & Boston Copper Co. at Butte.

DAVID H. LAWRANCE, of Denver, has just returned from a month's trip to Nevada, where he visited some of the principal camps.

H. H. HEDGES has returned to Los Angeles from Bluefields, Nicaragua, where he designed a mill for the treatment of gold ores.

E. J. BUMSTED, formerly with the Esperanza at El Oro, is now chief engineer to the Velardeña Mining & Smelting Co., in Durango, Mexico.

J. ALFRED MAYLAND, chief engineer of the Peñoles Mining Co., Mapimi, Durango, has resigned, and will open an office at Los Angeles.

G. C. HEWETT, of Colorado Springs, has been appointed consulting engineer for the old London mine, in Park county, Colorado. He is now on a short visit to Wyncote, Pennsylvania.

L. VOGELSTEIN & Co., New York, give the following figures of consumption of foreign copper in Germany for the month of January, 1907:

	Tons
Imports of copper	8,950
Exports " "	618
Consumption "	8,332

Of this quantity 7,129 tons were imported from the United States.

Mining Summary.

ALASKA.

NOME DISTRICT.

Recent reports from Nome state that the operators refused the demands of the union, and have formed a permanent organization. The miners demanded an increase in wages, to $4 per day and board, and directed that all non-union men should be discharged. The operators have decided to offer $3 per day of 10 hours and board, during the closed season, when only hoisting is done, and $5 per day during the open season, when the dirt is being sluiced. The result has been that many of the claims are being worked by non-union miners and the operators seem to have carried their point. The $3 scale will be in force until May 15, when the pay will be increased to $5 per day and board and lodging, which scale will remain in force until October 15. The second bench is not showing up as well as was expected. Many prospectors have sunk to bedrock without finding a color, and but few have discovered pay-dirt in quantity.

KETCHIKAN DISTRICT.

The Mamie mine shipped 30,000 tons of ore to the smelters in 1906. There are 1,200 ft. of workings, and 1,200 ft. of diamond-drill holes. This mine is situated on Kasaan peninsula, 5,500 ft. from the Hadley smelter, with which it is connected by aerial tram. N. O. Lawson is the manager and John Hampson the superintendent.——The Alaska

Map of Arizona.

Smelting & Refining Co.'s plant at Hadley has a capacity of 400 tons per day. The plant produces matte, but converters may be added to blow the matte to blister-copper. Paul Johnson is the manager.——The Mt. Andrew group has produced 9,000 tons of ore, which was sent to the Crofton smelter in British Columbia. W. C. Freeburn is the manager.——The Hadley Con. Copper Co. is operating the Stevenstown, Blue Jay, and other mines on the east coast of Prince of Wales island. The output is about 100 tons per day, the ore being rich in copper. George E. Green is the superintendent.——The Alaska Copper Co. is operating its mines and smelter at Coppermount, and also the Rush and Brown mines at Kasaan bay. The smelter is treating about 275 tons per day.

ARIZONA.

GILA COUNTY.

No more work has been done to prove the extent of the new sulphide orebody in the Old Dominion.——The Gem shaft of the Globe Consolidated Co. is down 535 ft., and is still in diorite. A station is being cut at the 500-ft. point. Sinking has been resumed in the Mallory shaft of this company, and driving on the vein on the 460-ft. level continues. ——The Mitchell smelter will be blown in at once. Ore and coke are arriving daily. The company will produce matte until the converter arrives.——It is reported that the Inspiration mine at Globe has been sold to the Lewisohn interests for $3,000,000.——The shaft of the Arizona National has cut 42 ft. of ore, assaying 12% copper.

CALIFORNIA.

NEVADA COUNTY.

The Bear River Tunnel Co. is driving on a good vein, carrying gold and sulphides. The company owns six claims. ——The Maryland mine will be re-opened. The manager, Bray Williams, has returned from an Eastern trip and reports that the property is well financed. The shaft will be sunk 1,000 ft. deeper.——The vertical shaft at the Boss mine, near Sweetland, is down 150 ft., and will be continued to 600 ft. The company expects to open good copper ore. Electric power is obtained from Colgate.——Some good ore has been struck in the Lincoln mine, near Canada hill, at the bottom of the 60-ft. shaft. The property is bonded to the Resartus company.——The annual report of the Brunswick G. M. Co. shows that the company is in good shape. The present work is done at a distance of about 3,000 ft. from the shaft, which adds to the working cost, and it may be decided to sink a new shaft. R. Gilman Brown has resigned the presidency and gone to London to live. Last year $100,000 in bullion and sulphides was won, and a $14,000 dividend was paid.

(Special Correspondence).—Otto Woehler is doing development work on the property recently bonded by the California Gold & Copper Co. There is a tunnel 900 ft. long which is proving the property.——El Oro Mining Co. is arranging to begin work on its gravel claims. The first work will be to re-open a 2,300-ft. tunnel, in the face of which an incline will be sunk to reach the bottom of the channel, which has proved very rich.——The Fairview mine, 21 miles north of Nevada City, will soon be ranked as a producer. The tunnel is in 325 ft., and has cut through a 30-ft. vein which runs from $4 to $6 in gold, carrying silver and some copper. During the coming summer, the company will install a plant to crush 100 tons per 24 hours.—— Mr. Bishop, of Tonopah, and associates, will commence work at the Eclipse mine, a few miles below Nevada City. ——The 15-stamp mill at the Mtn. Maid mine, near Nevada City, will be in full operation by March 15. There is a quantity of ore blocked out and the owners feel elated over the present showing.——The Bullion mine, south of Nevada City, is unwatered and development work will be resumed with a large force of men.——The Fruitvale mine, in the Washington mining district, is producing well. The new strike resembles ore from the famous Tightner mine, only eight miles distant. In one day $20,000 was taken out.——The Coan Mining Co. at Indian Flat is erecting a four-stamp mill. The shaft is down 75 ft., and there is sufficient ore blocked out to keep the mill running continuously.——The Dolly Madison G. M. Co., about five miles from Nevada City, intends to erect a 40-stamp mill this year. As development progresses the mill will be enlarged. There are 100,000 tons of ore in sight, which can be placed in ore-bins for from $1 to $2.50 per ton. A recent mill-run on ore from 300 ft. of the lode gave returns of $10 per ton. This property will undoubtedly be a good producer for years to come.

Nevada City, March 15.

PLACER COUNTY.

There is great activity on the Forest Hill divide, both in quartz and gravel mining.——The Pioneer mine, below Damascus, will be opened by a tunnel run at a lower level than any of the previous workings. The Southern Cross, on the north fork of the American river, has yielded some good ore, and it is to be consolidated with the Pioneer and a tunnel will be run nearly 6,000 ft. long, to cut all the veins on both properties.——The Rawhide mine, which lies farther up the river, has been producing some rich ore.——In addition to these properties, the mines at Snow Mtn., Bald

Mtn., Black Canyon, Sailor Canyon, and the Barton mine will be worked this season.

SHASTA COUNTY.

The Mountain Copper Co. is again in need of fluxes for its smelter at Keswick. Every mine manager in the district has received a circular letter from the company inviting shipments of silicious ores at once, although the first furnace will probably not be blown in for another month. It will not be as easy to get ores of this kind as it was two years ago, before the smelter shut down, as in the meantime the Mammoth Copper Co. at Kennett is consuming all the gold ore produced from Old Diggings and Quartz Hill, and even from Siskiyou county and southern Oregon. The White Oak and Crown Deep will probably be large shippers of silicious ores to the Mountain Copper Co.—— The Washington gold mine at French Gulch was recently sold for $150,000. There are three veins on the property.

SIERRA COUNTY.

A rich pocket was opened in the Fruitvale mine, situated on the Yuba River side of Chipps ridge. Andrew Fitzgerald, the superintendent, reports that $20,000 was taken from one pocket that was opened in the tunnel.——In the Downieville region several new properties are being worked. The tunnel at the White Bear is being pushed; and the Telegraph Drift M. Co. is working a force of men, developing the quartz vein. This mine is equipped with an electric-power plant, having generators on Goodyear creek.——The new tunnel at the Sebastopol mine is in 200 ft.——At the Papoose mine in Jim Crow cañon, the new mill is nearly finished, and will be in operation by April 1.——Work has again commenced at the Sovereign mine in Ladies cañon. Air-compressors, rails, machine-drills, and other supplies purchased last fall from the Marguerite company, will soon be delivered, and a new tunnel will be started that will tap the veins at a depth of about 1,000 ft. A 10-stamp mill will be built, and a flume one mile long will bring the necessary water.——At the Antlers mine on the Middle Fork, a lower tunnel will be driven for 1,000 ft. This property is being financed by H. W. Turner, of Portland.——The West Point company at Monte Cristo is working a force of men on the gravel deposit.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondenee).—With the advent of early spring general activity in the Georgetown district is noticeable, and during the next few weeks a number of old-time properties will be undergoing development. The Democrat Mt. Mining Co. is carrying on development work. The new 50-ton mill is running and concentrates are being turned out. The initial shipment was made this week and returns of $70 per ton were received for silver and lead. Early the coming week the aerial tramway running from the Moline tunnel will be started, and as there are over 2,000 tons of $16 ore awaiting transportation, the mill-bins will be kept full. Were it not for the zinc contained in the product, the ore would be shipped direct to the Denver smelters. Jerome Smith the manager, states that the work of driving the Kelly tunnel forward will shortly be started.——The Commonwealth and Delaware mines, situated in Peruvian district have been bonded and leased to J. A. Noone, who in turn transfered his privileges to the Togo M. & M. Co. The bond ealls for $26,000 and runs for three years. The Togo Co. will at once repair the old workings. These mines produced heavily of silver-lead ore during the years 1879-80, the average returns received in settlement being $45 per ton.—— Ten sets of lessees are at work on the Lamartine and all are in pay-ore. This property has produced $3,000,000 and the output will be kept up to the standard of former years.—— The Silver Leaf adit being driven into Republican Mtn., has intersected lode No. 3, and a big body of mixed iron and quartz has been encountered. No driving has yet been started as the manager, B. J. Martelon, is desirous of tapping lode No. 4, which lies about 100 ft. distant. It is believed that a rich pocket will be found as soon as the vein is reached, as from shaft-work a heavy production resulted a number of years ago.——Machinery has been installed at the Shively workings. The adit driven to cut under the old shaft is being advanced at the rate of five feet per day, and the work will be completed early in July. At that time the workings will be drained of water, at which time the mine will be placed in the shipping list.——Heavy shipments of concentrating ore are being made from the Pulaski, situated on Leavenworth Mtn. An average of 12 tons is being broken daily. The product is sent to the Newton mill at Idaho Springs, and by concentrating from four to five tons into one, settlement is made at the rate of $62 per ton.—— Tho Creole property, situated on Leavenworth Mtn., has been bonded and leased to D. F. Sprouse & Co., the bond calling for $25,000 and running for two years. The lower adit is being placed in working condition, and within the next few days the work of pushing the bore forward will start. Within 100 ft., the junction of the Creole and Argentine veins will be reached, and in view of the fact that a big streak of high-grade ore is showing in the winze sunk from the adit above, it is expected that a rich pocket will be uncovered.——Shipments are being made from the block of ground operated by H. Davenport on the Wide West. The ore is high-grade, carrying 420 oz. silver per ton and 20% lead.——Jos. Garbolino has a rich lease on the same mine, and is working to the east of Mr. Davenport.——The Uncle Jack M. Co., operating on Breckenridge Mtn. near Empire, has secured possession of 400 acres of mineral-bearing ground. In the holdings are included the Overland, Boston, Mammoth, and Abeel groups of claims. A. R. Perry, of Empire, the manager, announces that future work will include the driving of the adit started on the Mammoth, to intersect the Jupiter, Overland, and Boston lodes.——The Joplin tunnel on Republican Mtn. has been advanced for 475 ft. and within the next 70 ft. the heading will penetrate Gambetta ground. This property is considered one of the most promising lead and zinc propositions of Georgetown, as from sinking a shaft to a depth of 70 ft. a production of $25,000 resulted a few years ago. An additional depth of 380 ft. will be attained through the present workings.—— The Vidler tunnel was advanced during the month of February a distance of 204 ft. This work was performed on the eastern side of the pass and the average daily footage driven was better than 10 ft., as work was only carried on for 20 days. It is believed that the lode cut during the past week was the Arapahoe, which was recently purchased for $40,000.——Heavy shipments are being made from the Mineral Chief mine, on Republican Mtn. The ore is lead-bearing, returning from 70 to 75% of that metal, with silver varying from 70 to 80 oz. per ton. The seventh level is being driven forward and as soon as the objective is reached, a raise will be put through to No. 6, and at that time the mine will be the best developed property in Clear Creek county.——The Scott property, situated on Republican Mtn., is showing up strong. A body of smelting ore is being followed which measures 18 in. across, the average value being about $40 per ton in silver and lead. Shipments will be started soon. John White of Georgetown is the manager.——A new strike has just been made in the Douglas mine on Douglas Mtn. In running the drift east an eight-inch streak of silver and lead ore has been exposed which assays 40% lead and 45 oz. silver per ton. In the upper workings, a two-foot body of ore is showing which carries 34% zinc, 40% lead, and 35 oz. silver per ton. Shipments are being made to the Newton mill at Idaho Springs where the product is concentrated.——Peter Nelson, leasing on the Colorado Central, has a fine streak of silver-lead ore which runs $225 per ton.

Georgetown, March 11.

SUMMIT COUNTY.

(Special Correspondence).—The Abundance M. & M. Co. has just held its annual stockholders' meeting at Kansas City, at which S. B. Prevost was re-elected president. Work will be started soon.——The New York group on Gibson hill is being worked and ore containing lead, zinc, and iron pyrite has been shipped to the sampler, and to testing works, where the best method of treatment will be ascertained.——The Sallie Barber silver-lead and zinc property, situated on Bald Mtn., has been sold to J. C. Putner. A hoisting and pumping plant is to be installed at the main shaft. It is reported that at the bottom of this shaft there

is a vein of zinc ore three feet wide. This property has always been considered one of the best little mines of the camp.——The lessees working the lower levels of the Dunkin, an old-time producer, are making a fine showing. A second shipment has been made of 23 tons of ore valued at $40 per ton. The property is situated on Nigger hill.—— The Beaver Creek Mining Co., which has done some work in the Breckenridge district, has been re-organized under the title of the Swastika Mining Co., with a capital of $2,000,000. S. H. Dunlap, manager, states that work on the Minnie and Lucky mines will be started at once.——J. A. McDonald, the dredge-master of the Reliance Dredging Co., has been having the plant overhauled and is awaiting the decision of the Colorado Con. Mining & Electric Power Co. in connection with their intended sale of the Gold Pan plant to the placer company now owning the Swan and Blue River placer lands. The dredges on the Swan and Blue rivers are to be operated by electric power and the Reliance company is trying to make arrangements for similar power. Ben S. Revett is at the head of both of these enterprises, so it is probable that the old Gold Pan plant and interests will be absorbed by these two organizations.——Robert W. Foote of Breckenridge has obtained a right of way from the Rose of Breckenridge Co. to run a tunnel through the property to exploit his Ella claim that lies above it on Mineral hill, to the west.——M. Oehler of Jefferson reports that a streak of gold-lead ore has been opened in the main drift on the Mt. Guyot property. This ore assays $50 per ton. Mr. Oehler closed a contract with local men for extending the work 400 ft.——The Swandyke Gold M. & M. Co. has been carrying on experimental tests on ore obtained from the Three Kings mine, and it is stated that the results were good.

It is the intention of the company to further exploit the orebodies, with the idea of installing a treatment-plant. This will be a great help to the district, which has large orebodies but no plant to treat the ore.——E. W. Sebben recently reported on the property of the Square Deal M. & D. Co. He declares that the outlook for the company is excellent, and advises the continuance of the main tunnel.—— The Hibbs M. & M. Co., operating on Royal Mtn., is working three shifts of men and is taking out high-grade gold ore for shipment to the smelters.

Breckenridge, March 16.

TELLER COUNTY.

(Special Correspondence).—The Ajax mine on Battle Mtn., has produced about 1,000 tons of ore during the month of February, the average value for that period being in the neighborhood of $35. The ore is obtained on the seventh, eighth, and ninth levels, and is mined by both lessees and the company, the lessees producing in the neighborhood of 300 tons per month. Fifteen machine-drills are being operated, some of them on development work. At the meeting of the stockholders held at Denver last month, the proposition of the company building its own mill was brought up.

It was favorably considered and the construction of the plant should take place in the near future.—— The Little Clara lease on the Work property, operated until the 15th of this month by Marsh & Hodges, has been granted to A. E. Humphries of Denver and H. D. Thompson of Cripple Creek. This was decided at a meeting of the Work directorate held on the 7th inst.

The royalty on the new lease ranges from 15 to 65%, the lower figure being for ore under $30. It is said that lessees have agreed to give the Work Co. one-quarter of their net profits in addition to the above royalties. The property will have to keep up to its former record in tonnage and value to be able to stand these charges, but it is stated that the company is willing to make any reasonable concessions if the terms are found exorbitant. The lease is for 2½ years. —— Some of the slightly damaged machinery of the Economic mill, situated in Eclipse gulch, which was burned some weeks ago, has been sold to the Portland Gold Mining Co. It will be used in the new cyanide plant being constructed at Colorado City for the treatment of the tailing from the Portland mill.

Cripple Creek, March 18.

IDAHO.

IDAHO COUNTY.

(Special Correspondence).— Indications are that the Elk City district is coming to the fore again this spring, there being renewed activity at several mines near that city. The Thunder Mountain mine has been worked by a crew of 12 men during the winter, and they have extended a tunnel 640 ft. At present, the men are driving to cut the Champion vein at the mill-level. The tunnel will tap the lode at a depth of 400 ft. Rich ore that has been encountered, and one dike of low-grade free-milling ore has been found.—— Sixteen men are working in the Buster mine, near Elk City, and reports show that good ore has been encountered. This mine is owned by Frank W. Bradley.——The Frank Bush mine, on Red river, near Elk City, is being developed by the owners, Charles Whipple, J. Hillyard, and Frank Bush. Good ore is being taken out and reduced by a new mill, an invention of Mr. Whipple's.—— A three-drill compressor has been installed on the Twin Butte property, near Elk City, and is used in driving an 800-ft. adit. The surface showing on this property is good.

Lewiston, March 7.

(Special Correspondence).—Advices from Grangeville predict a rush into the Buffalo Hump country in Idaho this spring. This is due to repeated reports from prospects and partly developed properties, of rich strikes made since the district was closed for the winter by the heavy snowfalls. Los Angeles and other parties are buying stock, and the controlling interest in several of the properties.—— The Pierce City district is also going to be an objective point for many miners this spring. Last season's placer work was productive. The dredge near Pierce cleaned up on an average about $150 per day during the working season.—— Joseph Kieder, superintendent of the McKinley group of mines on the Salmon river, near Lucile, reports that a force of men has been kept at work on the property all winter exploring the four veins, and that a one-stamp test-mill has been busy every day. Each of the four veins has a width of three and one-half feet, and carries free-milling gold ore. More than 1,200 ft. of development work has been done. A five-stamp mill will be installed on the property next summer.

Spokane, March 11.

LATAH COUNTY.

E. F. Powers, and Dr. Haverson, of Palouse, and Frank Davidson, of Spokane, have bought the placer and quartz claims of Adam Carrico on Gold creek, 18 miles east of Palouse, in the Hoodoo district, and will begin work at once. Preparations are being made to take a force of men into the district and begin opening the properties. There is an eight-stamp mill on the quartz claim, and two hydraulic giants on the placer claims, and these will be put to work.

SHOSHONE COUNTY.

(Special Correspondence).—Five hundred thousand dollars was the price at which F. A. Heinze and his associates obtained control of the Stewart mine. There has been a complete reorganization of the company and new officers have been elected. The directors are: Charles Leonard, Butte; Stanley J. Gifford, New York; Edward J. Carter, Spokane; M. W. Bacon, Butte, and H. F. Samuels, Wallace. F. O. Merriam is general manager.

There are 85 men on the payroll. All the old equipment will be torn out and new put in. The air-compressor and all other machinery will be run by electric power, furnished by the Washington Water Power Co.——The Monarch Mining Co. reports that its ore-shoot is developing. Work has been done on what is known as the Atlantic vein, and with every foot or depth the ore-shoot increases in length.——A shaft has been sunk from the apex of this ore-shoot and 600 ft. of development work has been done from the shaft. The main level is 340 ft. below the surface. From the main level a winze was sunk toward the 490-ft. level and a raise was run meeting the winze from the 150-ft. level. The raise and winze show galena all the way. At a depth of 1,400 ft. below the surface, a tunnel 3,260 ft. in length, has been run and when

this tunnel strikes the vein, if the ore-shoot continues to lengthen, it should show a length of about 1,000 ft.——The Legal Tender Mining Co., which owns a group of 16 claims below Osburn, reports that a stringer of native copper 18 in. wide has been cut on the property. The find was made on the lower tunnel, which is in 300 ft.——The main vein on the Iron Crown property, east of Mullan, has been broken into and cross-cut for six feet without exposing the second wall. The tunnel is in 800 ft. and has attained a depth of 600 ft. The vein shows high-grade copper ore.——John Curran, manager for the Iron Spar Mining Co., states that ore, rich in copper, lead, and silver, has been encountered in the lode on which a drift has been run for 149 ft. The cross-cut was driven 181 ft. before it cut the vein.——Reports from Mullan are that a second strike has been made in No. 2 level on the Independent Mining Co.'s claims, Snowstorm Hill, between the Lucky Calumet and the Copper King. The vein is said to be a continuation of the Snowstorm-Snowshoe lode, is 10 ft. wide, has perfect walls, and is filled with quartz, galena, and copper-stained vein-matter.

The lower tunnel on the Lucky Friday mine owned by Spokane people, is in 172 ft. It is a cross-cut and will be 550 ft. long when completed. Three shifts are kept at work and the average is five feet per day by hand, but the company has ordered electric drills, which will make 10 ft. per 24 hours. These drills have been used exclusively in Colorado, but not yet in the Cœur d'Alenes. Electricity will come from the Washington Water Power Co.'s line. In the upper workings there is a shoot of ore 150 ft. long, which in some places is two feet wide. The property is near the Gold Hunter mill above Mullan, and adjoins the Gold Hunter mine.——Kennedy J. Hanley has bought a block of ground 2,200 by 4,500 ft., near Mullan, the tract including the Gettsbury, Independence, True Blue, War Dance, Victor, and Buckley claims, upon which $60,000 has been expended in development work. There is a tunnel in about 1,400 ft. on the east side of Mill creek. This is a cross-cut and was run to cut the Morning vein. This tunnel will be in the Morning vein after driving 400 ft. farther. This will be at a depth of 350 ft. below No. 5 tunnel on the Morning mine.

Spokane, March 10.

KANSAS.

CHEROKEE COUNTY.

The lead and zinc producers of this district are deriving much satisfaction from the policy now pursued by the smelting companies in paying the regular price per ton for zinc ore containing as much as 7% iron. Such ore was formerly penalized for its iron contents. The European smelters have for some time made a practice of deducting nothing for iron contents running as high as 4%, and the adoption of a similar policy by domestic smelters would appear entirely reasonable in view of the improved methods of smelting, by which the iron is saved and turned to account. Last week's shipments of zinc ore from this district were the largest in the history of the camp.

MONTANA.

PARK COUNTY.

The chief mineral district of this county is near Jardine, formerly called Bear Gulch, where the Kimberley Gold Mining Co. has its property and plant. This company has over 16,000 ft. of work done, principally in the way of tunnels, varying in length from 250 to 900 ft. The veins in the upper workings lie flat and the ore occurs in chambers. The formation is schist and shale, and the strike of the veins east and west. The output of the mine is treated in a 40-stamp mill and cyanide plant, which will be enlarged. The mine is now in shape to produce 700 tons of ore per day. There are 80 men employed at the property.—— The Crevasse and Helena Chief mines are situated four miles east of Jardine, and are owned by W. G. Conrad. The mines are opened by a 1,200 ft. tunnel, 30 men are employed, and a 20-stamp mill is treating 700 tons per month.—— The Buffalo-Montana is an old property situated at Cooke, 65 miles east of Gardiner. This mine has been idle for years, but now the old workings are being cleaned out and re-timbered, and development work is being pushed. The old smelter, which has been idle for 20 years, has been blown in, and is treating about 50 tons of dump material per day. The company is employing 100 men. Charles Eaton is the superintendent, and N. P. Trendennick is the foreman.

NEVADA.

ESMERALDA COUNTY.

Various reports continue to come from Goldfield concerning the labor troubles. One man has been murdered for his hostility to the I. W. W., and the mine-owners declared their intention to drive this organization from the camp. The business men organized and the mines closed down for two days to allow the men to join in an anti-I. W. W. parade, which, however, did not take place. All stores were closed, and skilled workmen and business men declared themselves supporters of the A. F. of L. Citizen's committees decided that none of the mines of the Goldfield district should be opened until the entire question of unions is settled, and that no member of the I. W. W. should be employed in the district as a miner, or in any other capacity. The wage-scale question has not arisen, and workers and

Montana.

operators state they are satisfied with the present schedule, but the result of it all has been that the mining business has been greatly disorganized and many miners are leaving the camp.

LINCOLN COUNTY.

(Special Correspondence).—New strikes are reported at Camp Thurman, a few miles southeast of Searchlight. The vein-matter is a honeycombed quartz, and specimens show free gold.——The first strike reported was that of John Thurman, who has a three-foot vein of quartz running well in gold. This was encountered on the Red Light claim. On the Jumper group, Harris and associates have encountered similar ore on another lode, and farther to the northeast Jesse Oliver has a good showing on the Christmas Gift, a claim presented to Oliver by a prospector last fall. Adjoining the Christmas Gift, William Unroe has opened an outcrop of quartz that within 10 ft. of the surface shows some free gold. These are some of the best surface showings encountered in the Searchlight district.——This district was discovered by John Thurman last September, and created excitement at that time owing to the surface showing on the Lloyd-Searchlight. This outfit has a shaft down 50 ft. and has driven a short distance in both directions on the vein. A mill-run at the Duplex last week gave returns of $75 per ton. This rock comes from a four-foot vein and was taken from wall to wall. The shaft will be continued down to water-level.——The Locke property, which adjoins the Empire, has let a contract for 100 ft. of sinking, and other contracts are to follow. This property has an excellent surface showing.——All of the recent strikes lie in an area a mile square, extending from the Empire on the south to the Nagle Buena Vista and Lloyd-Searchlight on the north.——Workmen are rushing work on the addition to the Quartette mill, and the next 10 days will see 20 stamps added to the present plant of that number. The additional batteries are being

mounted on the east side of the present mill, on concrete foundations. During the past year good ore reserves have been blocked out, principally on the 800 and 900 levels, where an ore-shoot 50 ft. wide was opened. The company has maintained a regular output of about $65,000 per month, and with the additional stamps this property may produce $1,000,000 per year.——Renewed activities in the Huntington properties promise to add materially to the payroll of the Searchlight and Crescent districts. These properties include the Denver Searchlight, the Superior Nevada, Crescent Searchlight, and Missouri Searchlight.——On the Denver Searchlight the shaft will be sunk to a depth of 400 ft. This will be a vertical shaft, and through it the development work will be done.——Development work will be done on the Jewell group at Crescent, where ore running $100 per ton has been encountered.——On the Superior Nevada there is good ore showing in trenches, shafts, and other workings. The 40-ft. shaft on this property will be sunk to the water-level. In the surface workings some mill-ore is shown.——The Crescent Searchlight will let a contract for 100 ft. of sinking on the Valley Ross. Water is expected at 100 ft., and the additional 100 ft. will be added to a 22-ft. shaft that has penetrated an ore-shoot 15 ft. wide.——The Missouri-Nevada Co. has acquired two claims east of Searchlight, adjoining the Golden Crescent and Horn of Plenty groups, two claims in the Crescent district, known as the Jack Pot and Golden Tom, adjoining the Mexican mine, and one claim at Camp Thurman, adjoining the original Thurman strike and the Nagle Buena Vista. Its Eastern office is at Sweet Springs, Missouri.

Searchlight, March 18.

LYON COUNTY.

Following many reports of a million-dollar cash deal for the Ludwig mine at Yerington, comes the news that no money was paid in the affair and only on option was secured. The latest reports state that Max Junghandel, a wandering prospector who followed the boom days in Goldfield, Manhattan, and other camps, has not been able to handle his option and has turned it over to F. J. Hagenbarth.

WHITE PINE COUNTY.

Excavation for the concentrator foundation of the Steptoe plant at McGill is about completed. About 500 ironworkers will be brought from Pennsylvania to work on the structure. There are already about 450 men employed at the plant, which will treat ore from the Nevada Consolidated and the Cumberland-Ely properties.—— The newly organized stock exchange will soon open at Ely.—— The shaft of the Ely Witch is down 115 ft., and the south drift is 586 ft. from the main tunnel. Some sulphides have been encountered.——Only 520 ft. of tunneling remains to be done to complete connection between the Ruth and Star Pointer workings of the Nevada Consolidated. Stations are being cut at the bottom of the Star Pointer shaft, for ore-pockets, and surface bins are being built.

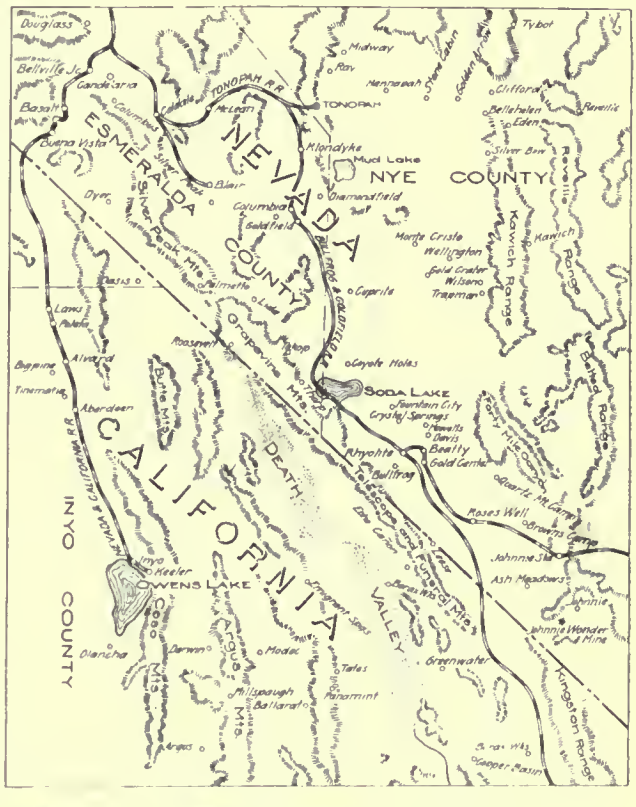
The diamond-drill on the Giroux property at Ely has struck good copper ore in the 1,000 ft. cross-cut, 108 ft. from the Alpha shaft.——The stock-pool of the Ely Consolidated company which was to have expired this month, has been extended for another year. Development work has reached the 390-ft. point in the Brilliant shaft of this company.—— The Bonanza group of claims, south of the Giroux property, has been sold for $20,000 to Hermansen & Sherrerd.——At Dolly Varden and Cherry Creek, things are looking well. The Victoria shaft is in sulphide ore.——The old Paymaster tunnel of the Nevada United Mines Co. at Ward has been cleaned out and re-timbered for 2,000 ft., which leaves 1,200 ft. to go to get to the breast of the tunnel, where cross-cutting will begin. Charles C. Gates is the superintendent and 25 men are employed.——A pumping-plant with a capacity of 325,000 gal. per day will be installed to work against a 1,500-ft. head at the Alpha shaft of the Giroux Con. company at Kimberly. The Giroux smelter is completed, except for the stack.——The Amalgamated Nevada M. & P. Co., has signed a contract for the machinery for a 100-stamp mill to be built on Baker creek. The mill will treat ore from the mines at Blackhorse and Osceola.——The final payment of $35,000 has been made on the Tip Top group, and these claims have been deeded to the Ely Central company.

OREGON.

BAKER COUNTY.

J. A. Howard, Kenneth McEwen, and John Arthur, of Spokane, have purchased for $15,000 a group of five claims known as the Poorman group, on Coin creek, in the new copper belt east of Baker City. Development work has already been begun. They have bonded the property to Detroit people for $25,000. The surface-ore on the group runs from $10 to $15 in copper.

On the Big Elk group of claims, near Granite, ore has been encountered assaying well in gold.—— The Daines Co., near Greenhorn, is working a force of men on their Belcher property, and the district is reported as being active.—— The Worley Co. has arranged to mill its ore at the Humboldt mill.—— The Standard Consolidated Co., operating in the Quartzburg district, is to ship a carload of cobalt ore to Thomas A. Edison. A 100-ton plant is in operation, and two carloads of cobalt concentrate per month have been contracted for. This is said to be the first shipment of



Map of the New Mining Districts of Nevada and California.

cobalt ore from a mine in the United States.—— At the Black Jack property, near Granite, the Congress vein has been cut on the 800 level, and drifts have been run each way on the lode. The adit at this level is now in over 2,300 ft., and will be continued to the Senator ledge.—— Charles Parker, lessee of the Pyx mine, took out $75,000 in gold during the past six months.—— A small crew is working at the Psyche. The 10-stamp mill will soon be started. W. W. Elmer is the superintendent.

JOSEPHINE COUNTY.

The Wounded Buck, in Josephine county, and the Forest Creek, Blossom, and No Name mines of Jackson county have all been merged into a new company, capitalized at $2,000,000.——The Harms company has recently purchased several properties which will be worked under E. T. Staples, the superintendent. New York and Cincinnati parties are interested.

LANE COUNTY.

There is a good deal of interest taken in the agitation to make the Bohemia mining district a part of Lake county, instead of standing as it does, part in Lane and part in Douglas counties. As many companies have their mine in one county, and mill in another, and the county seats are 70

miles apart, a great deal of unnecessary work is required of the operators to pay taxes and file papers in both places.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Colville M. & S. Co. has been incorporated to develop the Mountain Boy, Mountain Boy Fraction, Little Girl, Silver King, Copper King, and other claims in Park City, in the south half of the Colville reservation. The first shipment of ore from the Mountain Boy claim was 3,700 lb., which netted $637 over transportation and treatment. The present management shipped a carload of ore from the old dump which assayed 52 oz. silver per ton. The vein strikes northeasterly and pitches northwesterly. It has been opened by two cross-cut adits. From the No. 1 adit an inclined winze was sunk 170 ft., and lateral drifts were driven on the vein, following a rich streak of ore, from 4 to 18 in. wide. An adit was driven through the underlying limestone 265 ft., which did not reach the vein, but a connection with the incline was made by raising for drainage and ventilation. An adit is now being driven on the northwest side of the hill that will have to go 700 ft. to strike the vein at a depth of 330 ft.——The shaft of the Bootle Copper-Gold Co., on Belcher Mtn., is down 60 ft. to the foot-wall; a drift to the southwest is in 20 ft., and a winze down 15 ft., from the bottom, all in ore, which averages 2% copper. About 500 tons of ore has been mined and placed on the dump. The width of the vein cannot be surmised at present. The ore is iron sulphide. The company is employing 20 men. They have driven the No. 1 Belcher adit 60 ft. into the Bootle ground, and, as soon as the vein is encountered on that level, a raise will be run to connect with the winze. The vein strikes northeast-southwest and pitches about 50°. The collar of the Bootle shaft is 170 ft. above the No. 1 Belcher adit. This company recently purchased the Old Maid and other claims adjoining its original property on the southeast and is driving a cross-cut adit to tap a vein of iron-sulphide ore, which is supposed to parallel the Belcher vein.——At the Copper Key mine a connection has been made between the middle, or No. 2, adit and the bottom of the winze which goes down from the upper working, by a raise 40 ft. high. This mine has produced and shipped over 3,000 tons of ore, and there is much ore blocked out. The mine is now in better condition than ever, and shipping will be resumed as soon as the Belcher Mtn. railway resumes operation. It has been snowed in during the winter.——At the Winnipeg mine an adit is in 800 ft., and a survey has been made for a connection with the main shaft, at a depth of about 300 ft. The shaft is down to the 200-ft. level. Stringers of quartz containing chalcopyrite, similar to ore in the upper workings, have been crossed by the adit.——The Anonymous Mining Co. is following a good-looking vein of iron-sulphide ore from its lower adit.——The Oversight M. & M. Co. has done a large amount of surface prospecting during the winter along the supposed trend of the veins of the Oversight group. The Pin Money shaft is down 60 ft. on the vein, which pinched, but is again widening. A sample from across the vein assayed 2.45% cobalt, 2% copper, 44% arsenic, 25% iron, and 20% sulphur in addition to other constituents.

Republic, March 20.

OKANOGAN COUNTY.

The Molson Gold Mining Co., operating in the Okanogan country has placed orders for a 9 by 24 roll breaker, nine 1,200-lb. rapid crushing, quadruple-discharge, stamp-mills, with feeders, line shafting, pulleys, and belting; one No. 3 Merralls roller mill, with silvered-copper amalgamation plates for saving the free gold; a 50-h.p. steam-engine, boiler and accessories. The contract price for the equipment is $12,549, exclusive of $5,000 for installation.——The Mineral Hall company, near Conconully, will start driving on the last two veins cut in the tunnel early in April, and the ore will be shipped to the smelter at Grand Forks, B. C. From the mine the ore will be hauled by wagon to the railroad on the Similkameen river, which should be in operation to that point, by that time. The veins from which the ore is to be extracted run high in lead and silver.

SKAMANIA COUNTY.

D. D. Birks, of the Spokane Lead Mines Co., has returned from Metaline camp. He said that the workings of the May Bell claim are down 75 ft. from the surface. They have cross-cut a body of concentrating galena-ore for 35 ft. The width of the vein is probably 30 ft. On the hanging wall a drift has been run for 68 feet.

WYOMING.

ALBANY COUNTY.

Placer operations for gold are being planned on an extensive scale for the placer fields along Douglas creek in Albany county. It has been demonstrated that the district is rich, and a number of dredging companies are ready to undertake active operations. The American Gold Placer Mining Co. will install a powerful dredge; and in view of improvements in placer mining methods, it is likely that important results will be effected.

BRITISH COLUMBIA.

The following is the tonnage of ore shipped from and crushed at the Rossland mines for the week ending March 9: Centre Star, 1,920 tons; Le Roi, 2,415; Le Roi No. 2, 420. Total, 4,775 tons. The Boundary ore shipments for this week were: To Granby smelter: From Granby mines, 15,333 tons; from Emma, 60 tons. To B. C. Copper Co.'s smelter: From Mother Lode, 2,000 tons; from British Columbia mine, 530 tons; from Snowshoe, 600 tons. To Dominion Copper Co.'s smelter: From Brooklyn, 1,952 tons; from Rawhide, 1,408; from Sunset, 768; from Mountain Rose, 105 tons. To Trail smelter: From Snowshoe, 730; from Providence, 60 tons. To Nelson smelter: From Emma, 70 tons. The total shipments for the week were 23,616 tons, and for the year, 147,008 tons.—— During the week the Boundary smelters treated ore as follows: Granby smelter, 13,144 tons; British Columbia smelter, 3,831; Dominion smelter, 4,233 tons, or a total treatment for the week of 21,208 tons, and for the year, 142,438 tons.

On the 14th level of the Centre Star a station has been cut, and sinking toward the 15th level has started. When it is reached, the distance from the collar of the shaft will be 2,050 ft., or about the level of the Columbia river at Trail, and should be the water-level in the mine. The three electric locomotives for underground haulage in the Centre Star and allied mines have arrived and will soon be running. In the Centre Star stoping is going on in the 4th, 7th, 8th, 11th, and 12th levels. In the War Eagle, stoping and development is going on in nearly all the levels, while in the Iron Mask stoping and driving are confined to the 4th level. The development of the Idaho is progressing through the 4th and 12th levels of the Centre Star. The conveyor is operating in a satisfactory manner, and the rock-breaker is crushing all ore sent from the Centre Star and its allied properties, to the smelter.

MEXICO.

CHIHUAHUA.

The production from the camp of Parral for the week ending Feb. 23, was as follows: Shipped to smelters, 2,750; locally treated, 1,950 tons. The camp produced 10,895 tons during the month of January.——The Green G. & S. Co. is to change its headquarters from Temosachic to Concheño, which will make them near the Concheño-Navidad mines, the principal property of the company, and nearer the Ocampo, Pinos Altos, and a number of other properties.—— The Santa Barbara section of the Parral district has now 27 working mines, more than at any other time in the history of the camp.

SONORA

A new concentrator of 10,000 tons capacity is to be built at Cananea for the Greene Consolidated and Cananea Central properties. The present capacity of the two units is about 2,400 tons per day. The new mill will be entirely of steel, resting on a concrete base, and will be so arranged as to enable the ore to be handled by gravity. The present ratio of concentration is about 3.6 into 1, and this rate will be maintained in the new plant. L. D. Ricketts, formerly superintendent of the Old Dominion plant at Globe, will design the new mill.

Special Correspondence.

Summit	169,659	86,890	79,245	4,383	208,484	548,663
Teller	13,930,525	45,379	163	.....	.....	13,976,069
Total	$22,588,734	$8,499,743	$5,666,993	$1,844,002	$5,298,602	$43,899,075

In the above table the calculation is on the average market price of the minerals for the year. Gold, 20.67; silver, 0.66791; lead, 0.05347; copper, 0.19278; zinc, 0.06198. The zinc figured on actual spelter recovered. Eighteen counties that contributed slightly are omitted.

Cripple Creek is in Teller county, Leadville in Lake, Creede in Mineral, and Aspen in Pitkin. The San Juan region comprises San Juan, San Miguel, Ouray, Dolores, La Plata, and Hinsdale counties.

East Argentine comes to the front this week with one of the most important strikes ever made in the history of Clear Creek county mining. In running the lower level on the Tobin, a body of ore has been uncovered which measures from three to five feet wide, assays showing 2,02t oz. silver per ton. The ground has been opened for 240 ft. in length and the ore-shoot extends for the entire distance. The ore was lost a few weeks ago, but it was later determined that it was on the foot-wall. The Tobin was recently sold to a syndicate of English capitalists, and it is estimated that there is now blocked out $2,000,000 worth of pay-ore.——A rich strike has been made on the Star property, situated in the Peruvian district, better known as the Horseshoe. In running an adit to intersect the Star vein, a blind lode was cut at a distance of 95 ft. from the portal. A six-inch streak of ore is exposed that assays from 1,000 to 1,500 oz. silver and from 15 to 20 oz. gold per ton, with 20% lead. The adit is being driven forward in order to reach the next lode, which lies 150 ft. distant. The Star lode is an extension of the Revenue, which has produced in excess of $1,000,000.——On the Commonwealth vein in the Wilcox adit, a body of ore measuring from four to five feet wide has been followed for the last 1,400 ft. Recent shipments show net returns averaging $125 per ton in gold, silver, lead, and copper. Stoping is in progress and a height of 400 ft. has been attained. All indications are that the shoot will go through to surface, a distance of 300 ft. more.——Three feet of 292 oz. silver-lead ore has been uncovered in a stope being carried on the Sunburst. The ground has been opened for 80 ft. in length, but it is evident that the streak will run for a good distance farther. Heavy shipments are in order and a record-breaking production is being made. A. B. Montgomery of Denver is resident manager.——The new concentrator of the Jewell Mining & Leasing Co. was started this week. The mill has a capacity of 50 tons daily and is being fed upon dump-matter from the upper Mendota workings. The first shipment has demonstrated that the entire product can be handled at a good profit; by running from four to five tons into one, returns of $38 per ton are being received from the lead concentrate.——Driving is in progress on three lodes intersected through the Sidney adit, East Argentine. In the drift run south on the New York vein, a big body of mineralized quartz is being followed, with every indication that ore in paying quantity will be discovered shortly. The machine-drills are to be put to use again early the coming month, at which time better headway will result, both in the adit itself and in the drift.——Six inches of high-grade ore has been uncovered on the Bismark vein, being worked under lease by Otto Schatz & Co. The strike was made in running south from the point where Jos. Ebner & Co. started a cross-cut north. The ground has been opened for 20 ft. and the ore has been found to be continuous. Assays show 250 oz. silver per ton.——Work is being crowded to the limit on the Ramsdell mill, situated near the base of Lincoln Mtn. The buildings will be completed within two weeks, while the installation of machinery is under way.——Seven feet of ore has been encountered in the breast of the adit on the McKinley, situated on Lincoln Mtn. Assays yield from $9.40 to $17 per ton in gold, silver, and lead. D. W. Crandall, the manager, left this week for the East, where he will consult with stockholders concerning the erection of a 25-ton mill.——Ten inches of 330-oz. silver ore has been exposed in the workings of the Stemwinder. The ore is a decomposed sulphide and the discovery was made in sinking a winze 60 ft. from the portal of the adit. Driving is now in progress and as far as the ground has been opened the streak is still showing. Shipments were commenced this week to the local sampler.——A fine showing is being made on the Annie May, situated on Columbia Mtn. The cross-cut being driven to intersect the group has cut the first lode and a six-inch streak of sulphide ore is showing. Assays show 40 oz. silver per ton. E. E. Grubb, the manager, states that work will be resumed this week in the driving of the adit on the Annie May lode.——The Mazeppa vein has been intersected by the cross-cut being driven by the Mazeppa Mining Co. Scattered mineral is showing, and as soon as the heading has been advanced far enough, driving both east and west is to be begun. Manager M. Jacoby purposes continuing the adit ahead for at least 500 ft. more.——A company backed by Denver men has been organized for the development of the Paris group of claims, situated on Griffith Mtn. The bore is now in a distance of 500 ft., and it is believed a cross-vein will be reached with the shooting of any round of holes. The Paris vein was cut a few weeks ago by the Crowfoot drift being driven by the Capital Prize Mining Co., and ore measuring from two to three feet wide was uncovered. Tests show two ounces of gold, 30 oz. silver, with about 10% lead. It is probable that arrangements will be made for the working of the ground through the Crowfoot drift, as an increased depth of 1,000 ft. will be attained. Joseph Raymond is the manager fot the company.——Development work is being pushed forward on the Lebanon property, situated on Republican Mtn. A raise is being put through from the tunnel-level to make connection with the Everett workings, and an 18-in. streak of good-grade ore is being followed. The ore shows wire silver, and brings returns averaging about $60 per ton. It is understood that this property has been taken over by a syndicate of New

York capitalists, and that work upon a 50-ton concentrating plant will shortly be under way. The consideration is given as $80,000. W. H. Maxton is manager.——The Main Gulch Mining Co. is sending forth a heavy tonnage of high and medium-grade ores from the Smuggler group, situated on Brown Mtn. A number of leases have been granted during the past three weeks, and all the men are in pay-ore. C. I. Burt, of Silver Plume, is the manager.—— A contract has been awarded by Rees C. Vidler for driving the lower adit on the Arapahoe vein an additional 200 ft. This should take the heading under the rich pocket of ore that was extracted from the level above.

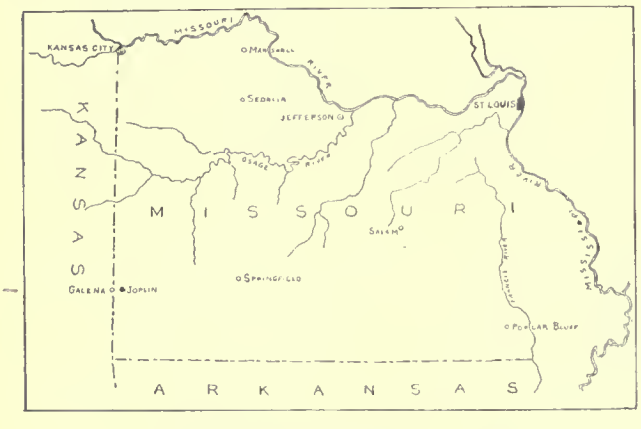
Joplin, Missouri.

Lead and Zinc Ore Prices.—Increasing Production.—Successful Drilling Operations.—New Shafts and Mills.—General Activity.—Expansion of Productive Area.

The highest price reported paid for zinc ore in the week ending March 9 was $53.50 per ton for some choice ore on the Continental Zinc Co.'s land in Joplin. The highest price paid for lead ore was $85.50 at Granby; $85 was paid in Webb City and $84 in Joplin. It is estimated that the smelters have $340,000 tied up in ore in the bins throughout the district, which they cannot move for lack of cars. There are over 200 cars of ore in the bins, the largest part of which is in Webb City and Carterville; Alba and Neck City are suffering seriously from the car shortage and much ore is piling up; the same condition exists at Orongo and Aurora.

Shipments.	Zinc Lb.	Lead Lb.	Combined Value.
March 9	12,297,000	1,912,030	$381,743
Year to date	116,610,670	16,582,380	3,431,154
Same period, 1906	99,594,820	14,135,120	2,758,395
Increase	17,015,850	2,447,260	675,759

Shallow lead is being mined on the Rob Roy lease just west of the Rex Mining & Smelting Co.'s land east of



Sketch Map Showing Position of Joplin.

Joplin. Burt Lyon and J. A. Wilson are doing some drilling on the south end of the lease, where there has never been any prospecting, and it is thought they will connect the rich run of ore between the Ideal mine on the Rex land and the Bumblebee on the Shewmaker tract.—— The M. K. & T. mine at Baxter Springs is keeping steadily in operation and making a splendid weekly turn-in of ore. The consolidation of this property with the Ward mine and the installation of an additional capacity of 600 tons per day, will make a big showing for that camp. Don McRuer is manager of this property. The Blue Bird is another very promising property in the Baxter Springs camp. It is owned by Ginder & Kraft; the ore was encountered at a depth of 55 ft., showing a 14-ft. face of lead.

At a depth of 101 to 109 ft. lead has been found in a drill-hole on the Shepherd tract east of the Rex Mining & Smelting Co.'s land east of Joplin and a shaft will be sunk at once. Harry Mead, and others of Joplin, are interested in the new find.——H. L. Kramer and son, of Cascaret fame, are planning extensive developments on their property at Carl Junction. They are sinking one of the largest shafts ever put down in the district, and are now letting the contract for four 400-ton concentrating plants to be erected on the property, work to be begun within two months. The son is residing in Carl Junction with the superintendent, Mr. Steel, who is in charge of the work.

The Ideal Mining Co. has made another rich drill-strike on their lease on the Rex land east of Joplin. The new discovery is the third drill-hole that has found good ore on this lease within the past three weeks and demonstrates that the Ideal has one of the largest deposits of ore found in soft ground for a number of years. The record of this mine in the past six months has been almost phenomenal, as it has paid all operating expenses with the lead ore that has been produced, leaving all zinc ore as net profit, which has amounted to from 50 to 60 tons per week. Messrs. McAntee and associates of Mt. Vernon, Ill., have purchased the mill and lease of the John Durby Mining Co., operating on the Burgner land, south of Carterville, and will at once begin to open up the ground in a thorough and systematic manner. There has been much work done in this mine, but it never paid dividends under the past management.

The Porto Rico camp, lying between Prosperity and Duenweg, southeast of Webb City, furnishes one of the best examples of the rapid development of mining territory to be found in the district. But eighteen months ago the only producing mines in that immediate vicinity were the three or four on the north end of the Porto Rico tract, more generally known as the Ground & Irwin lease, while today there are between fifteen and twenty big modern mills turning out ore at a lively rate, while as many more shafts are being sunk, opening up ore for more mills next year.——The recently organized Hawkeye Zinc Mines Co. has purchased the 20-acre lease of the Lyon Mining & Development Co. on the Connor land south of Carterville, and will soon begin the erection of a 300-ton concentrating plant at the shaft on the south ten acres, which Mr. Lyon put down to the sheet run of ore. This property ought to become a good producer.

Mexico.

The Explosion at Las Esperanzas.—News From Guanajuato.—Good Ore in the Carmen.—Railroad Building.—Transfer of San Cayetano.—Batopilas Output Increasing.

The removal of the debris after the explosion on February 18 at the No. 3 shaft of the Mexican Coal & Coke Co. mines at Esperanzas, Coahuila, which resulted in the death of 67 miners, has shown the damage to be not nearly as bad as was at first expected, and it is believed that the output of the company will not be materially affected. Certainly it is to be hoped that this will prove so, for the shortage of both home and foreign coal has caused a practical coal famine at smelters and industrial institutions throughout the Republic, some having to shut down aud others to work at half capacity. What was the direct cause of the Esperanzas explosions, whether from gas or dust, has not been clearly shown, but whatever the cause of this most disastrous of all Mexican mine accidents, it should lead to more strict regulations for coal mining in Mexico. The Mexican is more or less of a born miner, as he is always poking around the hills, and very few indeed are the accidents in metal mines, but of the dangers of coal mining he is wholly ignorant, and it is remarkable that this is the first real disaster in the Coahuila coalfields. It will, no

doubt, lead to the enactment of strict laws and regulations for the future.

In Guanajuato, the great Sirena mine of the Guanajuato Consolidated Mining & Milling Co. seems to be improving with depth, the vein on the sixth level having opened up to a width of 81 ft., with an average value of 36 *pesos* per ton, and the development work during January opened up some 100,000 tons with a value of about 3,000,000 *pesos*. And in the Carmen mine, held largely by the principal owners in the Guanajuato Consolidated, a fine body of ore rich in gold has been struck in the adit being driven to connect with the Pinguico mine. This adit is already 2,500 ft. long and is in pay-ore all the way, but this recent strike is of bonanza grade. There is still 500 ft. to go to make the connection, and it is expected that pay-ore will be found all the way. The Pinguico people, to whose property the Carmen adit is being driven, have given a contract for the installation of the mines and being shipped to the smelters. The Pinguico is producing rich ore.——Good progress is being made in the Cuajin drainage tunnel that is being driven under contract with the State Government by the Engineering & Construction Co., of New York City. It is estimated that one more year will be required to complete the tunnel, which is 26 ft. in diameter.

The San Pablo Mining Co., of New York, has purchased two claims adjoining the San Francisco and Mirador properties, at Ixtlan del Rio, Tepic. This company now owns 50 *pertenencias* in that part of Tepic, in addition to the San Pablo mines in the Ezatlan district of Jalisco.

Bullion shipments of 105,000 oz. or nearly $70,000 for February seem to justify the policy of the management of the Batopilas mines in re-investing most of the returns for 27 years until there are more than 50 miles of underground workings including the Porfiric Diaz adit, 10,000

Map of Mexico.

a complete Butters slime-filtration plant for their cyanide mill.

The Southern Pacific railroad has started work on the Guaymas-Guadalajara extension out of Mazatlan, and about 1,000 men are employed. News comes that there are 2,000 carloads of construction material at the port of Manzanillo, awaiting shipment into the interior for the Manzanillo extension of the Mexican Central railroad.

The transfer of the San Cayetano mines in Guanajuato from the United Mexican Mines Association of London to the San Cayetano Mines Co., has been completed. The English association was at one time heavily interested in mines in Mexico, but has disposed of its properties one by one, until only the San Cayetano mines remained. The association will now go out of existence, while the purchasers of the property will proceed to develop the mines on a large scale. More power will soon be available for mining purposes in Guanajuato, as the Guanajuato Power & Electric Co. is taking up additional water-rights along the Duero river in the State of Michoacan, and an additional hydro-electric plant will soon be installed to meet the increasing demand for power.——A good deal of high-grade ore is coming from ft. long. Just now Batopilas is attracting a good deal of attention. Mr. Stewart Tod, the resident engineer, who is now in New York, says he will turn out at least $1,500,000 this year. It is claimed that, although the mines have produced more than 20,000,000 *pesos* since Alexander Shepherd took them over in 1880, the stock has always been closely held. It is soon to be listed on the New York Exchange. In spite of the distance from the railway, Batopilas has at the San Miguel *hacienda* a 100-stamp mill for high-grade ores and a 25-stamp mill for low-grade ores, and a foundry that can cast its own stamps of 2,500 lb. apiece. Development has been slow and expensive, but this property is now in a condition to produce heavily.

It is rumored at Torreon that the A. S. & R. Co. is again negotiating for the purchase of the Torreon smelter, on which it at one time had an option, which was allowed to expire. The capital stock of the Torreon smelter was recently increased to $5,000,000 and the company is in a prosperous condition.——A group of New York men have bonded 290 *pertenencias* in Santa Eulalia for 1,250,000 *pesos*. The option is for 60 days and covers all the property owned by Lorenzo Arellano and A. V. Garcia in

this district.——About 70 men are employed at the Cuadras and Marina mines in the Santa Barbara portion of the Parral district. These mines are owned by the Marina Mines Co., an English corporation. The properties are developed by a shaft 500 ft. deep, and the ore carries gold, silver, and lead.

London.

The Transvaal Government.—The Exploration Company.—A Good Annual Report.—El Oro and Mexico Mines.—Estimate of Ore in Esperanza.—Strike in the Dolores.—Deep Leads.—General Mining Market.

The main subject of discussion in the Kaffir market just now is, of course, the newly elected Government in the Transvaal. What will the dominant party do with their power? The prevailing attitude here appears to be that indicated by the phrase "waiting to see how the cat jumps." There is a pause perceptible in the air somewhat similar to what happens after the deliverance of an *enfant terrible* or a Buster Brown that has let himself go in a polite assembly, on a topic forbidden by his elders. The view was expressed in my correspondence months ago that a Boer majority might not be so detrimental to the mine owners' interests as many then feared. That opinion is shared today by some of the leading financial writers, one of whom aptly remarks that: "Less than eight years ago this country went to war because the Boer Government refused justice to British subjects engaged in mining on the Rand; and now these same British subjects are turning with relief from the ministrations of the unsympathetic British Colonial Office to a sympathetic Boer ministry, at the head of which will probably be found the general who led the enemy's troops against us in the field. History records many instances of topsy-turvy judgments; but never, perhaps, such an amazing reversal of opinion within so brief a period as this."

That adroit medicine man of the Exploration Company, Mr. R. T. Bayliss, had an unpalatable pill prepared for his audience at the stockholders' meeting last week, but he got them to swallow it with fairly good grace. Nearly £100,000 written off for depreciation on South African shares is a dose in the taking of which a grimace on the part of the patient is pardonable. In regard to other fields of operation the Chairman gave a more cheerful account. He was able to state that the shares held by the Company in Mexican mines showed an appreciation over cost of £88,366. Interests in other (American) mining companies contributed a gain of £10,414, and the investments made up to the end of the year in copper mining securities showed an appreciation over cost of £85,479. On balance, the securities showed an advance of £183,000 over their cost price. In dealing with the Company's mining operations, the Chairman referred to the developments in El Oro (Mexico) at the 1,000-ft. level as of first importance, the ore on the big San Rafael vein that had given out at the 500-ft. level having come in again at the 1,000-ft. R. M. Raymond (the general manager) is confident that what has now been discovered is going to make a permanent orebody. The face of the drift now being run north has sampled, on the 1,000-ft. level, from 10 dwt. per ton up to 100 dwt. per ton, and the latest information is that the whole face of the drift, 5 ft. wide, shows an average value on sampling of 2½ oz. gold per ton and is in sulphide ore. From the occurrence of this sulphide ore, it is thought that the water-level of the district has been reached, and, if so, there is the strongest encouragement for the belief that the ore will persist in depth. With regard to the Somera mine, the Chairman held out the hope that they would meet with good luck there, but the pick of their basket in that district was Mexico mines of El Oro, and that by reason mainly of its small capital of £180,000. The Mexico mine has improved during the past eighteen months in the most remarkable manner, and the Chairman said it has proved to be a property of great importance and value. They are getting, in branch veins and local enrichments, in addition to the main developments, a considerable amount of high-grade ore, which will average something over 100 dwt. per ton. It seems to be the characteristic of that El Oro district that in the little off-shoots or branch veins from the main vein ore is found in a highly concentrated form. Among their other investments in the United States, they controlled the Tomboy gold mine, which during the past eighteen months had been making remarkable progress, both in its development and in the gross profit per month, and they were sanguine that further development in depth would be of an encouraging nature. Then the Exploration Company had secured a large participation in what is known as the Nevada Consolidated Copper Co. From all the information regarding that property, it is believed to be a remarkable one. The property will not be in the producing stage before the end of this year; the investment at the present time shows a large profit, but their advices with regard to the future earning capacity of the Nevada Consolidated are so good that they are retaining their interest, in the expectation of realizing a handsome profit at a later date.

A cabled report is announced from Esperanza (Mexico), stating that the consulting engineer's estimate of ore reserves is 141,600 dry tons metric, which should yield an operating profit of $1,480,000; cash balance, December 31, $2,281,475; ore on hand and in transit, $1,427,741; supplies on hand and absorptions, $200,000 American money. By putting these figures together and deducting the dividend paid in January, amounting to $1,181,250, a net value is arrived at of roundly $4,000,000 for the mine at the end of last year, not including the upset price of the plant and machinery. The position thus revealed is the subject of some debate among stockholders on this side, who would very much like to know whether the expression 'ore reserves' in the report means every ounce of ore known or thought to be exposed in the mine, or whether it refers simply to ore blocked out and available for stoping, and, if in addition to the known value, there are possible resources in the unexplored or partially explored portions of the mine. For the speculator, the charm of mining is not so much in the known as in the unknown or dimly perceptible future. From this standpoint the Esperanza report lacks in attractiveness, and the look of an inventory given to it has had a depressing influence on the market.

The microscopic rich streak of 0.06 in. reported in the new strike at Dolores (Mexico) announced at the beginning of the month now turns out to be six inches, a wrong code word having been used for the width. The value of the discovery is confirmed by mail. According to the further report published, the new vein (which has 450 ft. of 'backs' to surface) is parallel to and lies between the Alma de Maria vein, and the San Francisco vein, which it is also expected to strike rich about 100 ft. farther in the same cross-cut. From all present appearances the net value of the mine as given in the last annual report must be regarded as an ultra conservative estimate. The profit for January from Dolores is given as $25,000, or over 50% of the gross value of the month's production.

Another enigmatic cable is published from Loddon Valley (deep leads) for the bewilderment of the unsophisticated layman. "Borehole 128, end 500-ft. level, shows drop 15 ft. in bedrock as compared with last bore-

hole, 150 ft. distant." The news is not calculated, probably, to elevate stockholders' spirits or the Company's shares.

At the opening of the new fortnightly account, the depression in mining markets is reported as continuing. For some time past mining shares have been saved from complete stagnation by the active interest that has been taken in a few specialties, such as Rio Tintos, De Beers, and one or two similar descriptions; but the demand for even these has now lessened, and the mining markets can boast merely a modest improvement in a few Siberian issues. Business in Kaffirs was on an extremely small scale, and in the morning the market displayed some weakness. Rio Tintos were heavily pressed for sale from the bourse in Paris on the unfavorable advices from New York, and fell at one time to nearly £100, while Cape Coppers and Tharsis were freely offered from the same quarter. A sharp fall also occurred, in Zinc Corporations, a movement which was likewise not without influence upon the mining market as a whole. As regards Westralians, the only improvement was in Great Boulders; but Horseshoes, Great Fingall, and Oroya Brownhill all weakened. Barriers were dull and lower, under the lead of Zincs, which were somewhat heavily sold both on home and colonial account. The sales from the Colony were regarded as significant, and the offering on this side was accompanied by renewed rumors to the effect that the Company's process is a failure.

Leadville, Colorado.

Lower Production Last Month.—The Little Johnny.—Important Discoveries.—Activity on Breece Hill.—The Vinnie and Fanny Rawlins.—Pumping the Mammoth.—A Geological Surmise.

The production of the camp during the past month was less than in any previous month for a long time and cannot be easily explained, but the usual activity at this writing indicates a normal production for March.

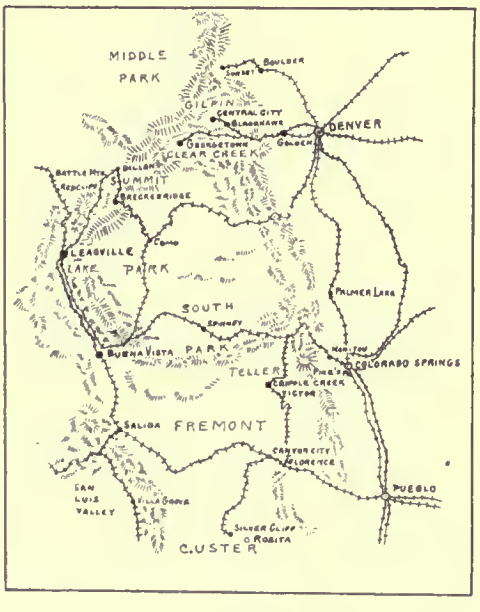
The Little Johnny mine still furnishes an occasional sensation. The recent strike of a body of copper ore in shaft No. 3 will, from present indications, furnish a substantial amount of that metal. In the past the No. 4 shaft has produced a fair supply of copper, but the new orebody is much more important. Even of more importance is the gold ore opened up on the 1,300-ft. level. It is impossible even after two weeks' development work, since the discovery, to give an approximate estimate of the value of the new ore-shoots. But pockets of ore running $100 per lb. and shipments of a quantity of ore with a net smelter value of over $100 per ton indicates its importance.

The different properties on Breece hill are all shipping ore. A few months ago, several Leadville miners took hold of the Elk, adjoining the Little Johnny and after installing a plant of machinery they started development work on the bottom level. A drift driven to the southeast has exposed a body of ore giving returns of $20 per ton and upward, and a steady production of 30 tons daily is being maintained.——Good progress is being made in sinking the Cleveland shaft, and the required depth will be reached by the end of March. The entire bottom of the shaft is in ore running $20 per ton; it is mostly galena. So far water has not been an important factor in sinking this shaft.

The lessees on the Fanny Rawlins are doing considerable work on the fifth level. Regular shipments are being made and the plan is to sink a winze to the St. Louis tunnel for air and to work the orebody at greater depth. The St. Louis adit has entered the Fanny Rawlins ground and exposed a strong ore-shoot.——The Vinnie is shipping 50 tons of ore daily and when connections have been completed with the Yak tunnel, the shipments will be increased. The discovery of a large body of exceptionally rich ore was made two weeks since, and the management reports this to be the most important discovery on that property for years.——The Crescentia, on Rock hill, has opened a body of lead carbonate of good grade and is shipping 25 to 40 tons daily.

The Triangle Mining Co. is conducting extensive development work both by drifts and diamond-drills. The manager, O. H. Fairchild, is not yet ready to give out information, but the north drifts are furnishing shipping ore. The results of the diamond-drilling will be of much interest to the public, as but little is known of the formations on that part of Breece hill. The Yak tunnel is being driven at the present with but one shift, but it is expected that arrangements will be completed at an early day to permit the adit to be driven into South Evans gulch to tap the ground of the Ollie Reed.

Machinery is being delivered for a power-plant on the property of the East Lake Mining & Milling Co. at the head of Lake creek. A dam is to be constructed and hydro-electric power employed for development work. Although the adit is now in over 1,200 ft. it will be driven at least 1,000 ft. farther before cutting the Washington vein.——Preparations are being made to resume operations on the Silent Friend, on Little Ellen hill. Since the property has been leased, arrangements have been made to install a modern plant of machinery. This mine has made a good record and the resumption of work should result in another shipper for Leadville.



A Part of Colorado.

While the large pumping plant is being installed on the Mammoth, the water is being bailed and at this writing is near the 400-ft. level. A station is to be cut at this point and ample pumping facilities provided, in anticipation of another flood such as caused the former company to abandon the enterprise.——For some time past, the probability of finding ore-shoots in the pyritiferous porphyry of Breece hill has been much discussed. This hill is known to have thousands of acres of such territory and but little prospecting has as yet been done to determine its value as an ore-bearing formation except a single shaft sunk on the Banker and a few hundred feet of driving by the Yak company. Many seams of ore exist so as to warrant the conclusion reached by the late August R. Meyer that below this mass of porphyry would be found important ore-shoots. The drilling now in progress at more than one point, should throw light on this subject.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

CRUSHING-ROLLS act upon the lumps of ore on the principle of the toggle joint.

BARYTES is used as an adulterant for white lead and is added to paper to give it weight.

THE Simplon tunnel is the longest deep tunnel in the world, being 12.4 miles in length.

MOST steel-makers agree that the cost of melting one ton of crucible steel is between $34 and $39.

THE original Blake breaker was patented in 1858, and gave the greatest movement at the mouth.

AROUND every conductor carrying a current of electricity, there is set up a magnetic field of force.

RIVETED PIPE is more widely used for a water conducting medium than any other kind of metal pipe.

THE leather industry contributed $150,000,000 to the foreign commerce of the United States in the year 1906.

A STAMP-STEM generally breaks just above the head and sometimes just below the tappet, the points of greatest strain.

GYRATORY BREAKERS act upon large, elongated lumps, on the principle of a beam supported at the ends and loaded in the middle.

THE Huntington mill is used to do the work of a stamp-mill in crushing gold ores, and often serves as a fine grinder for re-crushing jig-middling.

THE Kinkead mill is a pan-mill with a convex conical bottom or die, upon which operates a conical muller or shoe, of a gross weight of about 3,400 pounds.

THE tendency of the tappet is to push the cam away from the stamp during the act of being lifted, and this is greatest at the moment of leaving the cam, on account of the lateral thrust.

WE are asked whether quartz carrying gold in profitable quantity has been found in Placer county, California. Certainly; in many mines, particularly between Auburn and Newcastle.

THE correspondent who wrote to us concerning a vein of native arsenic in Mexico, will do well to write to the Slipp-Butler Co. at 45 Broadway, New York. They are dealers in arsenic and other metals.

IRON PIPE for conveying water to hydro-electric plants is rarely used in sizes larger than three or four feet in diameter. Cast iron is preferable to wrought iron, since it rusts less, and its life is practically unlimited.

WHEN water is admitted to only one part of the circumference of a hydraulic motor, the machine is termed a water-wheel. When water is admitted around the entire periphery of a hydraulic motor, the machine is termed a turbine.

THE Bay Counties Power Co., of California, has the longest transmission system in existence. Power is transmitted at 40,000 volts to Oakland, a distance of 142 miles from the main generating station, and to Stockton, 218 miles from the main power-plant.

THE steel in reinforced-concrete should be in comparatively small sections, well distributed through the mass. Wide flat bars bedded in concrete are not held as firmly as square and round bars of the same sectional area, and are not suitable shapes, for the reason that the concrete tends to shrink away from the flat sides.

IN mining bodies of native copper, it is the practice to cut the 'mass' with cape chisels having a ¾-in. bit, the successive chips being about ⅛ in. thick. The pneumatic hammer has been used successfully in place of the chisel and hand-hammer. At the Michigan mine, the cost is $3.15 per square foot, exclusive of power.

THE largest mass of native copper ever mined was found in the Minesota (spelled with one *n*) mine in the Ontonagon district, Michigan, in 1865. It weighed 420 tons, and the dimensions of it were: 46 ft. long; 18.5 ft., maximum breadth; 8.5 ft., maximum thickness. The mean width was 12.5 ft. and the mean thickness 4 feet. Twenty men labored 15 months to remove it from the rock, and the cutting of it yielded 27 tons of copper chips.

THE proper curve for the face of the cam is the involute of a circle whose radius is the distance from the centre of the cam-shaft to the centre of the stem; the lift of the cam will then be in the centre of the stamp-stem, and no pressure thrown on the guides until the toe of the cam has passed the centre line of the stem. The distance between the cam-shaft and stem is therefore fixed in the design of the cam, and if it is altered by wear of the guides, or guides of incorrect thickness, the lift will no longer be in the centre, and friction will result.

MORTARS can be sectionalized for convenience in transport, and the bottom part built of several pieces with machined faces, held together by longitudinal bolts turned to a driving-fit into reamed holes. The upper part, or housing, is made of boiler plate. A difficulty is found in securing the upper and lower parts together, since neither bolts nor rivets will stand the vibration. The only plan that has proved satisfactory is to provide a dove-tailed groove 2½ in. deep around the bottom, to drop the housing into this groove, and secure it by a caulked rust-joint.

WHERE the rainfall is abundant the ground-water roughly follows the outline of the surface, but it is less pronounced in its relief. It is nearer the surface in valleys than on mountain sides, and in a swamp it is actually at the surface. In the arid regions the ground-waters stand very deep. At Mapimi, Mexico, in the lead-silver mines they were first encountered at about 700 metres below the surface. Some observers have even questioned their necessary existence beneath excessively dry deserts. It may be, therefore, that locally they fail altogether.

THE NUMBER of drops made by stamps depends on the length of drop and on the proportions of the cam. If driven too fast the stamp will be caught again by the second arm before its fall from the first is completed—a danger that is increased by using cams with arms longer than the fall requires. A rapid drop assists discharge, by keeping the pulp in constant agitation within the mortar, and most mills are now driven from 85 to 95 drops per minute. At the higher rate the lift is limited to seven inches, and is further diminished if the speed is increased; it follows that the effect of each blow would be less, unless weight is added to the stamp. As instances of extremes of practice, mills are running at forty 15-in. drops per min., while others make from 100 to 105 drops per minute.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Correction.

The Editor:

Sir—My attention has been called to the editorial in the February 23rd issue of the MINING AND SCIENTIFIC PRESS, entitled the 'Burlesque of Mining.'

Prof. Samuel Aughey neither is, nor has been, a member of either the Smithsonian Institution or the United States Geological Survey and the *New York Commercial* is in error. The form of the report in question ought to have convinced you that this use of the Survey's authority is unwarranted and unjustly compromises this organization. Indeed, those familiar with the work of the mining geologists of the United States Geological Survey know that they do not furnish the daily press with articles of this kind. The official reports contain descriptions of mining camps which are conservative and based upon actual observation, and can not furnish "ammunition to pirates" except by deliberate misquotation. Unfortunately, there is no way to prevent editors and promoters from garbling statements from the most conservative reports. Your own quotation from 'Notes on Ore Deposits of Southwestern Nevada and Eastern California' contains a glaring error, which essentially changes the meaning of the original statement. The numerous quartz stringers are described in the Survey publication as "often cementing crushed areas" not as "containing crushed areas," as you state.

CHAS. D. WALCOTT,
Washington, March 6. Director.

[We are glad to publish this correction. The statement appeared in the *New York Commercial* of February 7. The mis-quotation to which Mr. Walcott refers in his last sentence, was not ours; we took the description verbatim from another newspaper, whose name was given. Of course, if we had supposed that the gentleman mentioned was in no way connected with the Survey, we would not have made the reference. The fact is, we supposed that he had been or was a subordinate officer of the Survey, and that he had written a letter concerning the mines or submitted to an interview, so as to become a part of the burlesque of mining. We wrote in good faith and the purpose of our remarks will be furthered by this incident, which proves that the name of the Survey and the Smithsonian is illegitimately used for the furtherance of mining schemes. In the meanwhile, we do not hesitate to apologize heartily for an unwitting propagation of error.—Editor.]

A Question.

The Editor:

Sir—In figuring out today the distance at which the centre of an electric hoist should be placed from the centre of the mine shaft, the question arose, whether the rope on leaving the drum should be parallel to the line through the centre of the drum and the centre of the driving pinion, or not. I maintained that it should be so, in order to minimize the loss of power, and also the wear on the teeth of the gearing; on the other hand, the officials of the company claimed that the position of the driving pinion in regard to the angle of the rope leaving or entering the drum, bore no relation to each other. I insisted that for best results the line of the rope must be parallel to the centre line of pinion and drum, while they claim that these equalities are not essential, and that the hoist could be 50, 75, or 100 ft. from the centre of the shaft without making any material difference, instead of an exact distance for centres with a certain height of head-frame.

I would like to have an answer published in your paper at your earliest convenience, and also leave the question open for discussion by engineers versed on this subject.

E. M. R.

Pilares de Nacozari, Sonora, Mexico, Feb. 21, 1907.

[The answer is that while the hoist is operating, the pull on the drum is constant, and it makes no difference at what point on the drum the power is applied. Therefore, there is nothing in the contention made by our correspondent. In most steam-hoists the pinion is on the rear of the hoist when looking toward the shaft. Therefore, a line drawn through the centre of the pinion-shaft and drum-shaft would be more nearly at right angles to the line of the hoisting rope.—Editor.]

The Butters Filter.

The Editor:

Sir—The discussion in regard to the Moore and Butters filter-processes has become most interesting to me and probably also to others interested in the treatment of slime. The following data may be of use to the profession; they refer to the Combination mill at Goldfield, Nevada.

The tanks and apparatus in use are as follows: Two slime-storage vats, two wash-water vats, the filter-box and canvas frames, one acid-box for the washing of frames, one vacuum-pump, one four-inch Butters centrifugal slime-pump, one two-inch Krogh centrifugal pump, valves and piping.

The pulp after agitation, containing 60% of a 1.5-lb. solution of cyanide, is discharged into the slime-storage vats (13.65 ft. diam. by 12 ft. high with slightly conical bottoms) ready for the filter-box. Two of these vats are in use, each one containing a mechanical stirring apparatus with paddles, keeping the pulp of the same consistency throughout. One vat of this capacity will easily hold three charges for the filter-box (the size of which is specified further on), and the two used in conjunction will hold about eight charges, all depending on the thickness of the pulp and cake to be formed.

The storage-vats, filter-box, wash-water vats, and vacuum-pump are all on the same level. The pump used in connection with the filter-box is placed about six feet below the vats, which simplifies the piping and operation of the valves. This four-inch centrifugal pump (patented by Mr. Butters) is especially adapted to the handling of pulp containing slime or fine sand, and has given little trouble to the operator or mechanic; it is the least troublesome pump in the mill.

The inside top measurements of the filter-box are 9 ft. 11½ in. by 10 ft. 2½ in., the sides extend 5 ft. 9½ in. above the cone, and from the discharge gate to the top is just 11 ft. 7⅛ in., with a capacity of about 785 cu. ft. when not containing the frames. The frames are 116¼ by 56¼ in., each having about 90 sq. ft. of filtering surface. There are 27 of these frames; six sets of four, and one of three. The four frames are connected at the bottom by ¾-in. rubber hose with the use of ½-in. iron nipples and Ts. Each set is connected by ¾-in. iron piping from the connection on the frames through the side of filter-box to the main (pipe on the outside) leading to the vacuum-pump. It may be mentioned here that the connecting of the frames to the vacuum pump should be at the top, in order to be convenient to get at whenever necessary.

About 35 tons of slime are treated daily at this plant, forming a ¾-in. cake on the filters with a 22-in. vacuum and washing with the same amount of vacuum for from 70 to 80 minutes with a weak solution of cyanide

(0.8 lb.), using about 10 tons of wash solution in that time.

Water is scarce in southern Nevada. If water could be used in the washing of the cakes, the time consumed would be about two-thirds that required with the use of a cyanide solution. Also if the slime could be agitated or treated in just twice as much solution as is used at present, necessitating less time of agitation and giving the same result, it would require still less time in washing the cake. The slime-treating capacity is now being enlarged for this purpose.

A record was kept of the charges, in regard to the time in forming cake, pumping of pulp in or out of box, thickness of cake, etc. The following is taken from these records when the plant was first installed:

	Minimum time. Minutes.	Maximum time. Minutes.
Filling of box with pulp	16	18
22-in. vacuum, while forming ¾-in. cake	19	22
Emptying box with 5-in vacuum on cakes	16	17
Pumping in weak-solution wash	15	18
Washing with weak solution, 15-in. vacuum	40	50
Pumping back weak solution	15	16
Filling with wash-water	15	16
Washing with wash-water, 22-in. vacuum	30	50
Sampling cake	7	10
Dropping cake with water	12	14
Running back surplus water	8	10
Sluicing	5	7
Total	198	246

Five months later when carbonate of lime became noticeable and with increased amount of slime in the pulp, the figures were:

	Minimum time. Minutes.	Maximum time. Minutes.
Filling	18	20
Vacuum	22	25
Emptying with 3-in. vacuum on cake	17	20
Pumping in wash	16	18
Washing with 22-in. vaccum	70	80
Sampling cake	7	10
Dropping cake	14	15
Running back water	8	10
Sluicing	5	7
Total	177	205

You will notice that two washes were used when the plant was first installed, but later only one. The reason for this change was the increased amount of slime; the saving of time; the exposure of the cakes the second time for so long to the air, causing them to crack; the wash-water often contained as much cyanide as did the weak wash and the second process gave better results.

At first, when the canvas was new, while pumping the surplus pulp out or wash-water into the box after the cakes had been formed, a vacuum of 5 in. was left on the frames, this being just enough to keep the cakes from slipping off and not enough to dry or cause cracking, but I found as the carbonate of lime began to form on the canvas (and where only the dipping of the frames in hydrochloric acid was resorted to) that five inches was too much vacuum and caused the cakes to dry and crack, but three inches proved more satisfactory.

After the washing of the cakes they are dislodged from the frames by water forced from the inside. The surplus wash-water is run back to the storage-vat by gravity and only that water (4½ to 5½ tons, depending on the amount of associated washed slime) remainng in the cone of the box is lost, which is necessary in sluicing the slime away through an 8-in. quick-opening gate-valve.

Very little has been said heretofore about the carbonate of lime forming on and in the filters, which in my opinion is quite an essential obstacle to be got rid of. Although somewhat simple, it is a necessary feature in the successful operation of the process, and it cannot be accomplished by simply dipping the frames in a 2% solution of HCl and water where any large amount of lime is used in the milling of the ore, say from 7 to 20 lb. per ton. It must be accomplished by washing with the use of vacuum, or any other means that either forces or draws the dissolving 2% solution of HCl acid through each cell of the cocoa matting for 15 to 45 minutes. If this process is used, the frames will only have to be subjected to the wash once in three or four months, depending on the amount of lime in use, whereas the dipping operation would have to be done at least once in two or three weeks and then it would be very unsatisfactory.

Although a small formation of lime on the filters does not seem either to interfere with the washing of the values from the cake or to diminish the net extraction, it greatly prolongs the operation and reduces the capacity of the plant.

One cubic foot of dry Combination slime weighs 76 lb. or thereabout, while 160 lb. in water only occupies one cubic foot. It was found that one square foot from a ¾-in. cake contained 5.03 lb. dry slime and 28% moisture, so, calculating from these results, in forming a ¾-in. cake you would be treating 6.11 tons of dry slime per charge. But from a larger test we found that 6.76 tons were treated in forming a ¾-in cake, due to the greater thickness of the cake at the bottom of the frame.

Now, I think I shall be stating the truth when I say that a plant of this size and design, when filters are kept free from $CaCO_3$, by washing for 70 minutes you can treat 50 tons of slime (having the same characteristics as that produced in the Combination mill) in every 24 hours, counting all delays, with the use of a 15-h.p. induction motor operating two mechanical agitators, one vacuum pump, one 4-in. centrifugal slime-pump, and three 2-in. centrifugal pumps.

One man per shift of eight hours can easily operate the valves from a platform near the filter-box, and have plenty of time for other mill-work.

The Butters-Cassel process for filtering slime is certainly a great improvement over all other processes and as an invention it ranks with the tube-mill in importance.

Denver, February 28.

Penn-Wyoming Copper Company.

The Editor:

Sir—In your issue of March 9 I noticed that your London correspondent refers to the Penn-Wyoming Copper Co., giving some figures that would indicate that the company is on the verge of a long and prosperous period of production. While but little reliable information concerning the venture is at hand, especially in regard to the financial side, in regard to which the company has always been decidedly reticent, still, I believe the prevailing impression among engineers is that the property is not as good as the reports sent out by the company would seem to indicate, and it may be well to sound a note of warning to British investors.

While some of the properties included in the consolidation have produced rich ore, I believe it is considered that many of these are worked out. The 16-mile tramway has always been an expensive affair and has caused much trouble. The mining, transportation, and treatment costs have always been high, and low-grade ores will not pay under existing conditions. The equipment is small and badly arranged. The smelter only contained three small converter-stands, and the furnace capacity was only 350 tons per day. The water-power has never proved adequate.

It is well known that the methods of financing this company were not the best. Agents of the company made a town-to-town canvass, appointing sub-agents in each place to sell stock. The result has been that a good

deal of stock has been placed with small investors, such as clerks and small merchants, who know nothing of the mining business, and are proverbially 'easy' in a matter of this kind. Each of these agents and sub-agents has received a liberal commission on the sale of stock, which commission, of course, has been paid by the purchasers, who are often induced to invest a sum that represents the savings of a life's work. I believe that in this country we are inclined to be suspicious of any mining enterprise that is financed in this manner. The capitalization is $10,000,000, and the stock has been sold to the public at prices ranging around 50 cents per share.

As for the London correspondent's letter, he speaks of the net profit for the last 90 days' run, just previous to the shut-down. How about the profits for a longer and more representative run? How about the net profits during 1905, when the company produced about 2,385,000 lb. copper at an estimated cost of 7c. per lb., when the figures would seem to show that the cost was 14c. per lb., just twice that estimated by the company. It is doubtful if any profit whatever was made in 1905. The old North American Copper Co., which was succeeded by the Penn-Wyoming, was over-capitalized and badly managed, and failed dismally, its assets being sold at public auction for much less than the debts of the company, making the stock worthless, and leaving the shareholders wiser, but poorer. The Penn-Wyoming Co. advertises to be paying monthly dividends at the rate of 6% per annum, and at the same time is selling stock at 50c. per share. What is the public to think of a concern that is paying unearned dividends, and at the same time making a strenuous effort to sell stock to wage-earners and small-salaried people?

T. S.

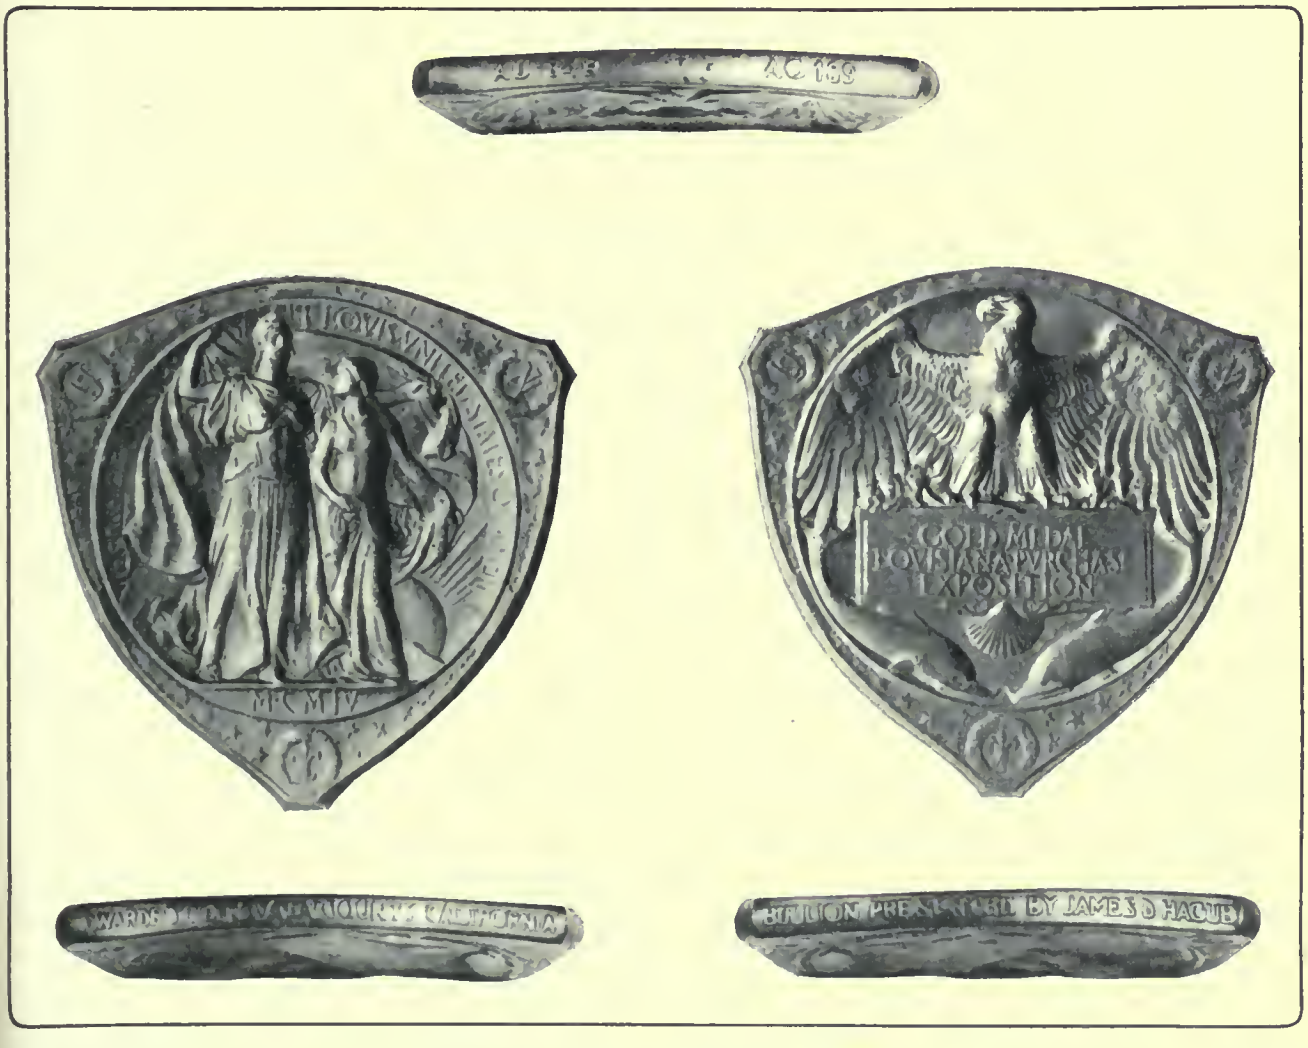
San Francisco, March 9.

A Handsome Medal.

The Editor:

Sir—Thinking that you may like to make some use of it in your paper, I send you herewith a photograph, which I have recently caused to be made at Tiffany's, showing five different views of the gold medal that was awarded for the mining exhibit of Nevada county, California, at the Louisiana Purchase Exposition at St. Louis in 1904.

At the time of the Exhibition I said to the Nevada County Commissioner that, if the exhibit received the hoped-for award, I should be pleased to supply the gold for the making of the medal in the form of fine bullion,



as usually produced from one of Nevada county's oldest mines, the North Star; and it is in fulfillment of that offer, after unavoidably long delays, that the medal, which was struck last year at the United States Mint, in Philadelphia, and recently finished at Tiffany's by the desired chasing and lettering on the rim, has just now been sent to its final destination in California.

The bullion is 849 fine in gold and 139 in silver; and the weight of the medal is nine ounces.

JAMES D. HAGUE.

New York, March 5.

SOME great electrical engineering projects have been submitted to the New Zealand Government by its engineer-in-chief, in the course of a report on the utilization of New Zealand's abundant water-power. One of the most notable schemes aims at tapping the Huka falls, and supplying the Auckland district with 76,000 h.p., the estimated cost of the necessary plant and works being $8,000,000.

How the Miner's Dynamite Is Made.—II.

Written for the MINING AND SCIENTIFIC PRESS
By WHITMAN SYMMES.

The nitric acid used in the dynamite works is made from Chile saltpetre (sodium nitrate), which occurs as a saline crust, or in strata, on the deserts of Chile. It is purified by crystallization, sacked, and brought in steamer loads to San Francisco. Besides being used in making the nitric acid, it is also used as a principal constituent of the 'dope,' with which the nitro-glycerine is mixed to form dynamite. As it arrives it contains about two per cent moisture, and, since a powder-maker loves moisture in his materials about as much as a dog loves fleas, the first step is thoroughly to dry it. This was formerly done by melting it in large iron kettles and allowing it to flow into an agitating trough, in which it was granulated while cooling. But the latest drying machines used for the nitre are the long cylindrical rotary dryers, now in common use throughout the country. The nitre is dried by a stream of hot air, without fusion, and with considerable economy in fuel over the old method. The nitre which is to be used for the 'dope' is ground after drying.

The nitric acid is made by gently heating the dried sodium nitrate with strong sulphuric acid in large iron kettles and collecting the nitric acid, which distills off, in condensers. Formerly a series of 50-gal. stoneware Woulff jars were used, but now rows of horizontal glass tubes 1¼ in. diam., and cooled by trickling water, are employed. This is known as the Hart system, and it is used at the California Powder Works and at the Vigorit. A charge for a nitric acid kettle consists of 1,100 lb. dried nitrate and 1,125 lb. sulphuric acid, as strong as possible. From this 690 to 700 lb. nitric acid is obtained if care is exercised in the regulation of the fire. The nitric acid obtained has a strength of about 94% (48° B.). If the heat is raised too high some of the nitric acid is decomposed into nitrogen tetroxide, oxygen, and water. The water is distilled over with the nitric acid and dilutes it, so that it sometimes happens that the last condensations, which come over when the heat is greatest, have to be rejected. Decomposition of the nitric acid also forms nitrous acid which interferes with the yield. Much nitrous acid in the mixture is also supposed to be a source of danger.

The nitric acid thus prepared is mixed with strong sulphuric acid in the proportion of about 3 lb. nitric to 5 lb. sulphuric. The two acids have a strong affinity for each other and the mixing generates considerable heat, so the mixed acids are allowed to cool before being used in nitrating the glycerine. Since the introduction of the contact process, a fuming sulphuric acid is being used with just enough sulphur trioxide to unite with the 4% of water in the nitric acid, the mixed acids being thus 100% in strength. Fuming sulphuric acid has not yet been used during the operation of nitration.

All the dynamite works in California take advantage of the elevations afforded them by the Contra Costa hills and place the buildings in which the glycerine is nitrated above the other buildings. Thus the nitroglycerine can flow by gravity from the nitrators to the separators, thence through lead-lined troughs around the hill to the storage tanks, and thence to the mixing house, where it is incorporated with the 'dope.' The buildings, where not sufficiently protected by the curves of the hill, have wooden bulkheads, filled with earth, thrown up between them. Since the nitrating house has the highest situation at the works, the mixed acids have to be pumped up there. This is done by running them into a cylinder of boiler iron (called a 'montejus'), closing the inlet cock, and turning on compressed air till the content has been forced through a pipe-line to the iron storage-tanks on top of the hill.

The glycerine used by the powder works is of a special brand called 'dynamite' glycerine, made to contain the minimum quantity of water. It is of a very pale straw-yellow color, and comes to the powder-works in tank-cars or in iron drums from manufacturers in the East. Some of the crude is now also being made in San Francisco. Some years ago there was considerable difficulty in obtaining glycerine that was strong enough, and the California Powder Works put up a plant for refining their own glycerine. Since then the manufacturers have been furnishing a glycerine, practically free from water, that gives good satisfaction. The wholesale price of glycerine varies from 13 to 16c. per lb., and, in making nitro-glycerine, it is about equally expensive with the nitric acid, of which three times as much is used.

The amount of glycerine that is nitrated in one charge differs at the different works. The Giant works use 620 lb., the California works 900 lb., and the Vigorit and Judson each 600 lb. For a 600-lb. charge, 4,500 lb. of mixed acid is weighed out in a tank-scales and run into the nitrating vessel, or 'converter.' Then the glycerine is weighed out on a small tank-scales and is slowly run into the nitrator in a thin stream. The works that have best developed their systems for recovering the waste acid use a little higher proportion of mixed acids, because it increases the yield within the limits of the recovery expense; the above 4,500 lb. might thus be increased 4,800, or even 5,000 lb. The nitrator is made of boiler-plate, and is about 4½ ft. diam., and of the same depth. The bottom slopes so that it can be thoroughly drained. The nitration of the glycerine generates a large amount of heat, therefore the nitrator is provided with iron coils through which cold brine is kept running. A double paddle dips down into the mixture, and if the temperature rises too high the workman who is mixing the charge shuts off the stream of glycerine for a few minutes, until the cooling coils have brought the temperature down again. At the Vigorit we used to mix at 82° F., using salt water from the bay in our coils. With refrigerating houses to chill the brine, such as are now in use at all the works, the temperature is kept down to 45 or 50° F. At one time the Giant used to mix at 95°, but most men think that is leaving too narrow a margin for emergencies, let alone the debatable question as to the yield that is obtained at that temperature. The brine is generally cooled by the ammonia absorption system, running on the exhaust steam from the power-house.

Below the nitrator is a large tank of water holding upward of twenty times the volume of the former. If a charge gets beyond control it will generally take fire before it explodes, and if this happens the attending workman opens a large cock and allows the burning charge to be 'drowned' in the large volume of cold water below. The nitrator is also fitted with a jet of compressed air for agitating and cooling the charge in case af emergency.

During nitration a small amount of reddish fume of nitrogen trioxide and tetroxide is given off, and these are carried by an air jet up a small stoneware chimney. The latter has a glass in it so that the workman can see the amount of fume that is given off, as the quantity increases largely when the charge begins to heat up. Our nitro-glycerine foreman at the Vigorit used to claim that he could mix his charge perfectly by watching the fume that was given off, without use of a thermometer; but we never tried to economize on thermometers. With the refrigerating system now in use, and the corresponding low temperature of nitration, almost no fume is evolved.

With a good supply of cold brine a charge can be run in half an hour, but a few years ago when we used to use the water from the bay in our coils, it sometimes took as long as an hour and a half.

When the mixture is finished, the charge is allowed to stand in the nitrator for a few minutes in order to be made as cold as possible. It is then run into a 'separator,' which is a square box made of sheet lead, 5 by 5 ft., and 2½ ft. deep, with a sloping bottom. It is provided with a funnel which can be raised or lowered, so that the liquid can be drained out to any desired level. When the charge comes into the separator it is homogeneous, the nitro-glycerine existing as tiny globules diffused throughout the mass of the acids. In 20 to 40 minutes these globules have risen and formed a layer resting on the acids, the reason being that nitro-glycerine has a specific gravity of 1.6, while that of the mixed acids (after nitration) is 1.7. While the mixture is standing in the separator a workman takes note of its temperature, because the acids are generally still more or less active in nitrating a little more of the glycerine, which, of course, gives rise to heat, and which might easily make the charge take fire. There is a glass in the separator, and when the workman sees that the separation is complete he gradually lowers the funnel untill all of the nitro-glycerine has been skimmed off the acids. It runs from the funnel into a washing tank, 4½ ft. diam. and 7 ft. deep, made of redwood treated with paraffin oil. In the washer it is churned with lukewarm water (which has a little sal soda in it) by means of a spray of compressed air introduced at the bottom of the tank. When the air is turned off, the nitro-glycerine, which is heavier than water, quickly settles to the bottom, and the water is drawn off the top through a cock in the side of the washer.

The washing is important, because nitro-glycerine that has been thoroughly washed is a stable compound; on the other hand, if it has any acidity, decomposition will gradually set in, and in time it will spontaneously explode. At the Vigorit works we used to wash five times, three times with the weak soda solution and twice with water. Water from the bay is used. The workmen test the water with litmus paper, and when the wash-water shows no acidity the washing is stopped. The nitro-glycerine is then run into a weighing tank, and the amount obtained from the charge of glycerine is noted for the benefit of the superintendent. The wash-water runs off through some long skimming-troughs, from which a little nitro-glycerine is taken and added to the other in the weighing tank at the end of the day.

The separators have no cooling coils in them, but there is a jet of compressed air to cool them in emergency. If a charge takes fire the workman runs it into a drowning-tank. Our nitrating and separating houses used to be a little distance apart, a condition which is compulsory in Europe. One day a charge in the separator took fire, and the workman in charge got 'rattled' and ran. The foreman in the nitrating-house, not having his whistle signal answered, went to investigate, and found the charge on fire. At first he too ran, but after getting a couple of hundred feet away he changed his mind, went back to the burning charge, turned the drowning-valve, and ran it out into the bay, where it exploded without damaging the works. After that I followed the good example of the Judson works and consolidated the nitrating and separating machinery in one building. Such an arrangement places more eggs in one basket, but it enables the foreman to keep his eye on all the eggs.

A few years ago the yield of nitro-glycerine from each 100 lb. of glycerine charged used to be about 200. It would vary from charge to charge, from as low as 190 up to 210 lb. The different works were making averages between 200 and 205. Then, side by side with the struggle to increase the strength of the acids, attempts were also made to increase the completeness of the separation; for, of course, there was no wisdom in making so precious an article as nitro-glycerine and then letting it run away in the waste. It was generally known that the colder the charge when it entered the separator, the quicker and larger was the separation. The California Powder works began the practice of putting ice in the tank that supplied the cooling water. Then Mr. Frank Roller, superintendent of the Giant Powder works, erected an elaborate refrigerating house, in which to chill the waste acids and obtain a second skimming of nitro-glycerine. This method he finally abandoned in favor of the simpler one of chilling the charge thoroughly in the nitrator before sending it to the separator, and that is the system in general use today. The refrigerating system has increased the yield not less than 5 points, or 2½ per cent.

When the Peyton Chemical Co. commenced shipping mixed acids three years ago, it was found that their contact-process acid raised the yield from 200 or 205 to 218 and 220 lb., an increase of 8 or 9%. Since that time so much attention has been bestowed upon the second boiling of the sulphuric acid that its average strenth has been brought from 95 up to 97 or 98%, and the yield from a combination of the best chamber-process acid and the freezing system is now between 218 and 220. When the contact acid plant at Hercules is completed the yield at all the works will be better than 225, and before another year has gone by persistent effort will have raised it to 230, out of a possible 246 pounds.

When the powder 'trust' was formed three years ago there was some apprehension among the mine owners that the price of dynamite might be advanced. The above increase in yield shows that the 'trust' managers did not need to take any such unpopular step; for by "attending to business" and improving their processes, they have, in the nitro-glycerine branch of their business alone, made savings that mean as great a profit as if they had increased the price of 40% dynamite from 10 to 10½c per pound.

The use of sulphuric acid from the contact process greatly improves the separation, because such acid is perfectly clear. The intense boiling of sulphuric acid from the chamber process contaminates it with lead and iron sulphates, carbon, and silica from the pans. Such acid is always cloudy, and cannot be sufficiently purified by settling. The fine particles seem to interfere with the rising of the nitro-glycerine in the separator. At one time I experimented in separating out this foreign material by running the acid through a centrifugal machine, but after the advent of the contact process such a step became unnecessary. The contact acid is also free from arsenic and lead, and contains less iron, all of which interfere with the nitration.

After the nitro-glycerine has been skimmed from the acids in the separator, the 'waste' acids, as they are called (because once upon a time they were wasted), are run off through a pipe and are recovered. Now let us figure up what we put into a nitrator and what we get out in the form of nitro-glycerine, and then we shall see about what is left in the 'waste' acids.

Our charge consists of, say, 600 lb. glycerine, 1,687 lb. nitric acid (94% strong), and 2,813 lb. sulphuric acid (96%). The acid contains 1,586 lb. pure nitric, and 2,700 lb. pure sulphuric, and the other 214 lb. is water. If the glycerine is completely nitrated it will have taken up 1,233 lb. pure nitric acid, with formation of 346 lb. water. Our waste acids will thus contain all of the sulphuric

acid, 353 lb. pure nitric, and the water that was originally in the mixed acids plus the water formed during nitration, totaling 560 lb. Their composition will thus be 74¾% sulphuric acid, 9¾% nitric acid, and 15½% water (not allowing for the little nitric acid that escaped as red fume during nitration). Since we never get a complete nitration in practice, the nitric acid will be slightly greater and the water slightly less than the figures given. If we obtain a yield of 220 (or 1,320 lb. nitro-glycerine) instead of the theoretical 246.9, then there is 65 lb. glycerine that

Sorting Ore at Palmilla Mine.

we did not obtain in the form of nitro-glycerine and that is yet to be accounted for. Some of this partly nitrated glycerine was carried over with the nitro-glycerine in the separation and dissolved in the wash-water—because the di-nitrate is quite soluble in water, whereas the tri-nitrate (nitro-glycerine) is very nearly insoluble. But most of the glycerine is still diffused in the acids, as a di-nitrate, for the latter does not rise in the separator as easily as the nitro-glycerine, and is thus left behind. If we could make a perfectly clean separation of the various nitrates of glycerine, the problem of recovering the waste acids would be greatly simplified because the glycerine products, if left in contact with the acids, will in two or three days spontaneously explode. At one time I made experiments in separating the glycerine products in a centrifugal machine (just as cream is nowadays skimmed from milk) and the separation was so clean that the waste acids stood safely for three years; but so far as I know, such machinery has never been used in manufacture.

The method employed at all the plants is to run the waste acids through what is called a 'de-nitrator.' This is a chamber lined with acid-proof brick into which a jet of steam is blown. By diluting the acids and heating them, the nitric acid is decomposed and driven off as the red fumes of nitrogen trioxide and tetroxide, mixed with oxygen. At the same time the nitro-glycerine globules floating on the surface (which escaped the separator or have been formed since) are vaporized and burned up.

The oxides of nitrogen are carried into condensing towers filled with coke, quartz, or stoneware balls, to expose a large surface to the water that is kept trickling down. Hot air is blown into the tower and the red fumes are thus converted back into nitric acid again. Seventy per cent or more of the nitric acid contents is thus recovered as a weak nitric acid of 40 to 50% strength (35 to 40° B). As there is no demand for nitric acid of this strength in the vicinity of San Francisco, and as nitric acid cannot be concentrated in any simple apparatus above 68% (because the water then distills over with the acid) this valuable material was all formerly wasted; but now it is being carefully saved and made by the powder works themselves into ammonium nitrate and other products.

The sulphuric acid that comes from the de-nitrator after separation of the nitric acid has a strength of 63 to 70% (50 to 55° B). It is then boiled in the sulphuric acid recovery, first in lead and then in iron pans, as described for the concentration of chamber sulphuric acid. The heat carbonizes and thus destroys what remains in the acid of the glycerine products, and the last of the glycerine is thus entirely eliminated. A few years ago only about 80% of the sulphuric acid was recovered. But the fumes from the last pans, which consists of about half water and half acid, are now more effectually condensed by means of condensation towers. Up to 95% of the sulphuric acid is now recovered. This is as good a result as is achieved by chamber sulphuric acid works, which only concentrates to 93½ per cent.

Ore-Sorting House at Alvarado's Mine.

(TO BE CONTINUED.)

KAMES are mounds of water-laid drift, sand, or gravel, rather poorly stratified, and built at the ice margin of a glacier, by glacial drainage. They are a form of morainal drift.

The Parral District, Mexico.

Written for the MINING AND SCIENTIFIC PRESS
By F. LYNWOOD GARRISON.

This famous silver mining district, in the State of Chihuahua, was once one of the most productive in Mexico, and though long decadent it now bids fair to resume its wonted prosperity by virtue of American capital and energy. A recent brief visit enabled the writer to gather a few notes and observations that may be of interest.

The general geological conditions of the Parral district

Santa Cruz Hill, Parral.

are those of the western Sierra Madre, or rather the eastern flank of the western branch of this great mountain system. The rocks are essentially made up of folded, faulted, and uplifted Cretaceous limestone, accompanied by vast Tertiary igneous deposits. This limestone has been positively identified as Cretaceous and is not Paleozoic, as was once supposed, though lithologically it resembles the mountain limestones of the Appalachians. This limestone is not exposed in the immediate vicinity of the town, but it appears at the Jibosa copper mine, near Jiminez, a few miles east of Parral. In and about Parral there is an association of folded slates associated with, and cut by, igneous fissure-flows and dikes of both acidic and basic character. Most of the eruptive material is rhyolite and dacite with their breccias or agglomerates and tuffs, the latter usually indurated. The rhyolite flows are supposed to be later than the ore deposits and the orebodies occur in andesite covered by the rhyolite, except where erosion has uncovered it. My friend, Mr. F. J. Keeley, of Philadelphia, has kindly made microscopical sections of some of the Parral ore-bearing rocks, and we found their structure to be rhyolitic and not andesitic, since there appears to be in them an absence of triclinic feldspar, which is one of the essential characteristics of an andesite. Further studies of these rocks may perhaps show some to be andesitic, rather than rhyolitic, but it would appear to be an error to assume, as has been frequently done, that the silver ores of Parral are in andesitic rocks to the exclusion of others. It goes without saying that the only safe and proper way to settle questions of this kind is with the microscope; in fact, the practical value of this instrument to a working mining engineer should be more generally recognized than it is. Whether the gray shale and slate associated with the eruptive rocks are altered sediment or metamorphosed (schistose) eruptive has apparently not yet been ascertained and perhaps never can be; further petrographic examinations may show them grading into eruptives and one eruptive shading into another.

One of the most evident characteristics of the Parral ores is their highly silicious character, the ore-bearing rock having usually a micro-felsitic structure of a greenish-gray tinge Alteration products, such as chlorite and epidote, are common in the veins and on their walls. Some of the deposits contain an abundance of zinc-blende and galena, but the characteristic Parral silver ore is a dense, silicious rock, carrying the silver in a sulphide form generally associated with much pyrite, and in the upper levels of the mine with alteration products, such as silver chloride and iron oxide. The silver ores are commercially called 'dry,' and in the older metallurgical practice they demanded an admixture of lead ore to insure proper smelting.

The existence of zinc in the silver-lead ores of the district appears to have been a decided detriment in the

On the River, at Parral.

past, owing to its objectionable characteristics in the old smelting practice, and until modern methods of treatment could make such zinc minerals commercially valuable they were neglected or thrown away.

The vein zones of the Parral district are pretty well defined, the majority of them having a general north and south trend. It must not be supposed that they are all, or even most of them, sufficiently rich to be productive throughout their length; the good ore is undoubtedly localized in spots and over restricted areas, but the

orebodies appear to be numerous, rendering the general prospect for the camp most promising.

Mining work was first begun in Parral during the year 1632, and at Santa Barbara, fifteen miles to the southwest, as early as 1556. At both places the gold ore appears to have attracted the attention of the Spaniards, and was taken out in large quantity from rich pockets near the surface. The proportion of gold, however, seems to have decreased rapidly with depth, and the pockets were soon exhausted. Copper is found in several places near Parral, but in the early days it attracted no attention, being valued only for the purpose of making *magistral** for use in the *patio* process.

Some new copper prospects are now being developed that must be considered encouraging; they are chiefly composed of chalcopyrite and bornite underlying the silver-lead-zinc ores in certain localities. At any rate these copper sulphides appear to come in with depth and usually do not give any indication of their presence at the surface. Whether they exist in quantity sufficient to be of commercial importance remains to be determined.

The Santa Barbara ores are said to carry much more lead than those of Parral, and in former days they were largely used as 'softeners' for the more silicious Parral ores. The galena and zinc-blende seem to increase with depth in the Santa Barbara veins, and are accompanied by some silver sulphide.

In the early days both Parral and Santa Barbara had their 'chloriders' (*buscones*), those human gophers who dig and delve out the richer superficial portions of orebodies to their permanent detriment or everlasting ruin. This class of miners is not peculiar to Mexico, but is familiar to everyone acquainted with the silver-lead districts in the desert areas of Nevada, Arizona, and California.

Probably few, if any, of the old Parral mines reached a great depth, their history being similar to that of most old Mexican camps in that their operation was suspended by inability to handle the inflow of water when a considerable depth was attained, although at Parral and Santa Barbara the ore thus abandoned is said to have been enormously rich—800 to 900 oz. silver per ton. The older operations at Parral appear to have been centred about Santa Cruz hill (Fig. 1), which was once assumed to contain the Mother Lode or *Veta Madre*—a favorite expression with the Mexican miners! This lode or orebody is on the southern slope of the hill and trends east and west; it carries the Ronquilla, Apodaquena, Tajo, Prieta, and other shafts. On the northern side of Santa Cruz hill there is a lode running east and west, containing the Tecolote, Jesus Maria, and Aquilarena shafts. Both of these lodes are said to have been rich and profitable, but the old shafts and workings were badly placed. The average assay of the ore from this hill probably ranges between 30 and 50 oz. silver per ton, with occasional bunches of higher grade. Much good ore is said to have been left in the old workings, soon to be recovered by the new American companies coming into the district.

The most notable mine in the Parral district is the Palmilla, owned by Pedro Alvarado, a Mexican made famous by American newspapers. Both the richness of this mine and the eccentricities of its owner have been greatly exaggerated by the scribes, Senor Alvarado being neither a fool nor a Midas, however much his policy in operating this mine is open to criticism. The Palmilla property is a couple of miles west of the town of Parral, and has been opened by shafts in the top of a high hill on whose crest a number of veins outcrop. The ore is a silicious material carrying large quantities of silver sulphide, together with sporadic bunches of galena and zinc-blende. The prevailing local opinion seems to be that this mine is located upon a great east-west ore-bearing lode or zone, and numerous attempts are being made to find other rich deposits or spots upon it. One can stand on the top of Palmilla hill and follow with the eye a long line of head-frames running for miles to the east and west over hill and gulch. My stay in Parral was altogether too brief to permit careful observations, much less a study, of this most interesting, and in a way, fascinating operation; tens of thousands of dollars are being spent to find another Palmilla—let us hope, not in vain!

There are a large number of shafts on the Palmilla property, one or two being at least 500 ft. deep. The water-level appears to be between 500 and 600 ft., and the ore at this level is said to be very rich and in great quantity; the high-grade ore, I was told, ran as much as 7½ kilo. (234 oz.) silver and 79 gm. (2.528 oz.) gold per ton. The low stuff averages 1½ kilo. (46.8 oz.) silver and 2 to 10 gm. (0.064 to 0.320 oz.) gold per ton. The crude ore raised from the shafts is hand-sorted in a primitive manner, the richer being sacked and shipped to certain smelters and the lean thrown on the dump. Recently, I understand, the low-grade material on the dump has been sold to an American company, which proposes to treat it by cyanidation. The Palmilla orebodies are among the very few in the district that carry any considerable quantity of gold. As far as explored, no copper ore has been encountered here.

A notable feature of the Palmilla mine is the enormous cross-vein of calcite, which appears to cut across the orebodies; in the side of the road leading up to the mine this vein is about a hundred feet wide, and I was told it can be traced to the north and south several miles from this point. It is practically barren of valuable metals. I was told there was no faulting in the Palmilla orebodies, but this is open to doubt. Although the Palmilla or another property of the same name was worked in the early days of this camp, its value was not realized until recently.

Magistral is an impure mixture of cupric and ferric salts, produced by roasting copper and iron sulphides, and was used in the *patio* when sulphate of copper ($CuSO_4$) or blue vitriol was not available.

ARTIFICIAL GRAPHITE.—This industry, like that of carborundum, owes its development on a large scale to the inventive genius of E. G. Acheson. The process consists in the electrothermic transformation of amorphous carbon into graphite. The carbon in the form of bars and rods, produced by a similar method to that employed for making carbon electrodes for arc lamps, is heated to a high temperature in a resistance furnace, very similar in type to that employed in the manufacture of carborundum, and during this heating is completely transformed into graphite. The product has been employed chiefly in the electrical industry, but recently the process has been extended, and the graphitization of lumps of anthracite coal and coke is now carried out. The resulting material is displacing natural graphite in many of its varied uses. In 1904 some 1,450 tons (metric) of artificial graphite were produced, 1,000 h.p. being continuously employed. The plant has now been duplicated owing to the increasing demand.

THE Yukon-Tanana region, which has recently been investigated by representatives of the U. S. Geological Survey, includes that part of the interior of Alaska delimited by the Yukon and Tanana rivers and the international boundary. It is 300 miles west from the boundary to the junction of the two rivers, and the greatest distance in a north-south direction between them is 175 miles. The area is about 40,000 square miles, or more than half that of the State of Washington.

Notes on the Copper Range.

Written for the MINING AND SCIENTIFIC PRESS
By AN OCCASIONAL CONTRIBUTOR.

The Trimountain shafts, in the copper region of Lake Superior, are placed 1,000 ft. apart along the strike, with double-track standard-gauge railroad running beneath them for taking the ore to the mill. At certain points the track is laid at a grade that will allow the empties to be easily run down under the bins by a man, without motive power. The railroad car used takes 41 tons of broken ore when full, and is the recognized measure of the quantity stamped. Over the shafts are combined shaft and rock-houses, usually made of wood and steel, respectively.

Fig. 1. Trimountain No. 2 Shaft.

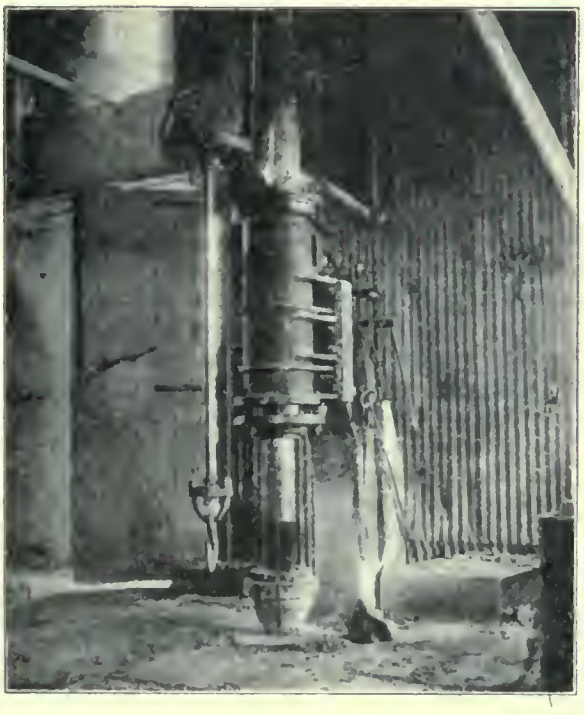


Fig. 3. Air-Lift and Hammer.

In height they are seen up to 100 ft., with their sheave-axles as much as 85 ft. from the ground.

The skips hoist 2.5 tons on an average, and are of the self-dumping type. As the skip approaches the surface the signal-man, in his box near the sheaves, rings a warning electric bell for the rock-men, when the ore is shot onto the plates above the grizzly. To break the velocity of the heavy pieces, a wooden buffer, made of three 8 by 8-in. blocks, armored with 3-in. rails on the upper side, is suspended by chains just above the level of the grizzly. The grizzly itself is 10 ft. 6 in. long, slopes at about 37°, and is made of 3 by 12-in. plank with a strip of manganese steel 1 in. thick and 4 in. wide, screwed onto the top. An alternative construction is to use an inverted 50-lb. rail on which the same 4-in. strip of manganese steel is riveted. The width between the bars is three inches. These forms of grizzly answer admirably and are practically indestructible. The old type of a single round bar is apt to break, and is continually distorted, giving an irregularly sized product. (See right-hand grizzly in Fig. 2).

About eight feet from the foot of the grizzly are two

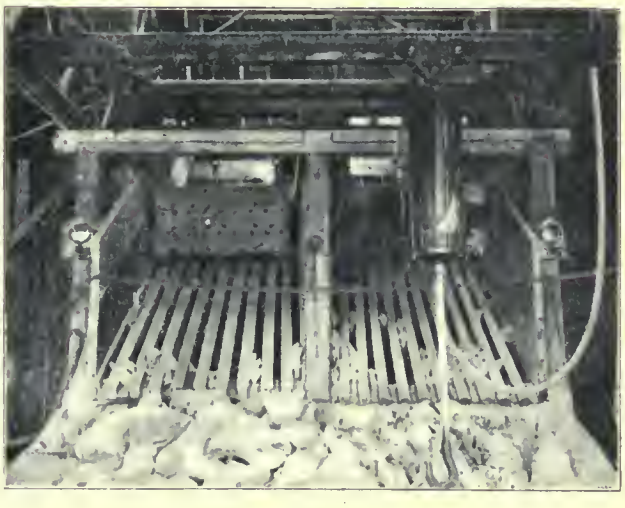

Fig. 2. Grizzly at Trimountain No. 4 Shaft.

12 by 24-in. Blake crushers with the tops of their jaws at the level of the ground. A space in between them allows of a temporary accumulation of copper ore, for when the skips are being dumped at a good rate the 'rock-men' are the hardest worked people in the district. Oddly enough they are also the most poorly paid.

One of the Champion shafts use a Gates (No. 7½) crusher, beside the Blake machines. It is convenient, in that it crushes faster, but it is more troublesome when

Fig. 4. Mass Copper at Champion Mine.

'mass' (chunks of native copper) gets into it than the Blake. Ordinary mass is picked out by hand, and thrown aside. When a piece is too heavy to move, or is too big for the crushers, it is attached by a chain to the hook of the 'air-lift' (seen in foreground of Fig. 2), raised from the ground, and taken some 20 ft. to the drop hammer (or air-hammer). The air-lift has a 10-in. cylinder and has air at 60 lb., so will carry about two and a half tons. The air-hammer (Fig. 3) will then break up the piece sufficiently to allow of its entry to the crushers. As these have only a stroke of 2 ft. 8 in. as

maximum, and as the efficiency of the blow diminishes with the size of the rock under them, they have been gradually replaced by drop hammers, like those used for pile-driving, and worked by the same kind of engine. The hammers weigh 2,800 lb. and can be raised a clear height of 20 ft. if necessary. Such a blow will crush anything, and rapidly cleans copper from its surrounding gangue. The shoes on the drop hammers are of the same shape as that shown on the air-hammer, and are made of manganese steel. They last indefinitely, whereas those made of cast iron were broken within a week.

The cleaned mass does not go to the bins, but is shot out from the rock-house to the ground below, whence it is taken monthly on flat cars straight to the smelter. The monthly 'rodeo' at Trimountain, shown in Fig. 4, netted about 50 tons, the largest pieces weighing 1,600 to 1,800 pounds.

Mining in Depth at Cripple Creek.

In the last annual report of the Portland Gold Mining Co., the consulting engineer (Victor G. Hills) says:

The report of the United States Geological Survey on the geology and gold deposits of the Cripple Creek district has just been issued. It confirms what most Cripple Creek mine operators have expected for many years; that a very considerable portion of the rich ore-shoots of the district do not extend to 1,000 feet in depth. The time has long since passed, if there ever was a time, when there was any use of trying to blind ourselves to this plain fact. This general condition applies to the Portland mine, for the fact is that there appears to be a considerable less number of ore-shoots below the 1,000-ft. level than above. Yet the whole truth in regard to the condition at this mine is *not* discouraging, and as compared to a majority of the mines of the district is rather flattering. Some of the earlier ore-shoots have pinched with depth, while others were only discovered at considerable depths and did not extend to the surface, and some continue to the greatest depths yet reached, and have even increased in size or grade for the last 100 ft. The condition regarding the ore deposits with depth, is concisely stated thus: The 900-ft. level was the poorest yet opened. The 1,000-ft. level was much more productive than the 900. The 1,100-ft. level is proving poorer than the 1,000-ft. level, although some of the important veins have not yet been cut. During the past year work was started to develop the 1,200-ft. level. Three winzes were started at points far distant from each other and on different veins. On the No. 1 vein the winze was sunk to a depth of 150 ft. to water-level, all in good ore, and drifts were started at the bottom with the purpose of making this the next general level of the mine, and thus save some expenditures in shaft stations and long cross-cuts. Drifts were run on this vein 27 ft., all in ore, when rising water decided the abandonment of this level, and drifts were started at an even 100 ft. below the 1,100-ft. level. This drift is now 114 ft. long and still in ore, and it is not known whether the shoot will be longer or shorter than on the level above. The grade of the ore is decidedly better than on the 1,100-ft. level.

THE Chicago tunnel system for handling freight, mails, etc., will probably soon be doing a large freight business, as it is reported that contracts have been made with 26 railways for handling their freight between the business district and the several freight stations. There are now about 30 miles of tunnel with narrow-gauge tracks operated by electric motors, and mails are now carried in this way between the railway stations and the post-office.

Railroad Tunnels.

They should, if possible, be straight, especially where there is but a single track (for with a double-track there is no chance for a head-on collision) inasmuch as collisions in a tunnel would be peculiarly disastrous. For depths of 60 ft. or less, a tunnel is rarely expedient, and an open-cut to that depth should be counted on.

The most favorable material for a tunnel is firm rock of moderate hardness and of a durable nature, especially if free from springs, and lying in horizontal strata. In soft rock, in shales (even if hard at first) and, in earth, a lining of hard brick or of masonry laid in cement-mortar is necessary.

A tunnel should have a grade in one direction for ease of future ventilation, for drainage, and for easier observation or inspection. Provided the length does not exceed 1,000 ft., no special arrangement is essential for ventilation, either during connection or afterward. Beyond that, and generally during construction, either shafts are carried up to the surface, or means are provided for forcing air through pipes from the portals. After the work is finished, however, except under peculiar circumstances, nothing of the kind is necessary.

Shafts often draw air downward, and frequently, even when aided by a steep uniform grade, do not secure ventilation. The Mont Cenis tunnel, under the Alps, completed in 1871, is 7.5 miles long, and has no shafts, although it grades up from each end, which is the most unfavorable condition for ventilation without shafts. It was made so in order to facilitate drainage, especially during construction. Ventilation is maintained by air forced from both ends. The Hoosac tunnel, in Massachusetts, is 4.5 miles long, has shafts, one of them 1,030 ft. deep, but they were put in for expediting the work by increasing the number of points of attack. If placed too near to one another the extra cost of shafts more than balances for the economy of rapidity of construction.

In excavating the tunnel itself, a heading or drift 5 to 8 ft. high and 3 to 12 ft. wide, is driven and maintained 10 to 100 ft. in advance of the main work. In rock, this heading is just below the top of the tunnel, so that men may conveniently drill holes in the floor for blasting out the rock. In earth, the heading is driven along the bottom of the tunnel, that being the most convenient for enlarging the aperature to full tunnel size, that is, by undermining the earth and letting it fall. In earth, the top and the sides of the heading must be carefully prevented from caving before the lining is built. This is done by placing side-posts or stulls and caps, with lagging to form temporary supports for the sides and roof of the excavation. This is gradually removed as the brick or masonry lining is carried forward.

The lining, when of brick, is usually from two to three bricks thick (17 to 26 in.) at the bottom, and 1½ to 2½ bricks thick (13 to 22 in.) on top. When made of rough rubble in cement, it is about half again as thick. It is important that the bricks or the stones should be hard and laid in good cement. The brick should be molded tapering to the shape of the arch, so as to give good joints. As the lining is finished in short lengths, and before the centres are removed, any cavities or voids between it and the earth should be carefully and compactly filled up.

DURING the past year special attention has been attracted to the American iron industry, on account of its remarkably prosperous condition, and by the publicity which has been given to attempts to effect a merger of important Southern iron interests. Another feature has been the commencement of active exploration work on Western iron deposits.

On Technical Writing.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

It goes without saying that careless writing is opposed to clear thinking, therefore technical men ought to be wary in their use of terms and precise in their style. Barry once said that scientific men were the only ones that had anything to say and of all people they knew least how to say it. Without further preamble, I beg to state that among the publications received last week were the proceedings of the two leading organizations of mining engineers, namely, the American Institute at New York and the Institution at London. Being interested in the question of standardization of usage in technical writing, I glanced over the pages of these bulletins to see to what extent they erred. The results are interesting, and I give them, not without fear of the thunder of the secretaries, nor without appreciating the humor of the situation. Of course, I have not written even these few introductory sentences without perpetrating some blunders and in my sequel of criticism there must be many errors, awaiting the detection of a more able critic. People that live in glass houses should not throw stones, but surely those that live in houses with windows need not deny themselves a little exercise of the fore-arm. So here goes. The first eighteen are from the bulletin of the American Institute of Mining Engineers; the second eighteen are from that of the Institution of Mining and Metallurgy. The equality of citations should prove the absence of animosity.

FROM THE INSTITUTE.

1. "In Mexico, the filter is handled by one Mexican peon per shift. These peons learn quickly and are entirely satisfactory."

The plural of *peon* is *peones*. As it is a foreign word, not yet generally accepted in English, it should be italicized.

2. "The absence of sulphides in all the ores, except in the cherty skeletons, was *very* complete."

Absence is complete or it is not. *Very* is redundant.

3. "The pay-streaks from 4 to 15 ft. *in width*, lie in well-defined *chutes* and overlapping lenses. It is noteworthy that only those *chutes* or lenses *which* now reach the surface contained calcite and manganese dioxide."

Wide would be better than *in width*. *Chutes* is wrong; according to the usage of the Institute itself, this term should be spelled *shoot*. *Which* should be *that*, for the clause limits the antecedent.

4. "The parallel shear-zones, now converted into metalliferous lodes, with extensive *chutes*, and lenses of *pay ore*, all dip toward the east."

Chutes is again wrong. A *chute* is an inclined passage for the transfer of material; an orebody of definite shape and pitch is a *shoot*. According to the style of the Institute, *pay ore* should be hyphenated. The two words are linked by an intimacy of meaning.

5. "From the size of small pebbles up to 6 in. *in* diameter."

Here it should be, preferably, "six inches in diameter;" if the small number is not to be spelled and *inches* is to be abbreviated, then it should be "6 in. diam.," which is consistent; it is also better style, because it avoids the two *in*.

6. "A *very* clean concentration of the mill-*tails*, producing a final material containing *very* low values."

Very is redundant. *Tails* is colloquial; the technical term is *tailing*. Why use the plural when only one kind of thing is meant? Moreover, no one makes a concentrate *of* a tailing; a concentrate might be made *from* such material, which would then cease to be a 'tailing,' becoming a 'middling.'

7. "The *middlings* from the second 10 stamps passed with the *tails* from the table to the vanner."

Why the plural? Here again the ugly and colloquial form of 'tailing' is employed. The use of the plural is an example of the hankering for the abstract in place of the concrete—a basic blunder in writing.

8. "It was found that the final tails were of *very* low grade; the result being *somewhat* surprising."

Another superfluous *very*. Unless we know the scale by which the writer measures the tenor of his ore, the *very* suggests a comparison without meaning. *Somewhat* is an excrescence; it is the pretence of moderation.

9. "As no copper had been found *in* the analyses, the reason for the phenomenon was *somewhat* obscure."

Here we have it again. When a man does not know what a thing is, he calls it a phenomenon; it is not *somewhat* obscure, it is *obscure;* and so is the reason for this sentence (meaning the other fellow's, not mine!). Copper is found *by* an analysis and *in* an ore.

10. "It was next attempted to size by *spitzlutten*." "The slimes were conducted into a set of 3 large spitzkastens arranged in a series."

The italics are in the text. Why is *spitzlutten* in italics and *spitzkastens* not? Both are foreign words. The plural of *spitzkasten* is the same as its singular. The numeral ought to be written *three*.

11. "In the extraction of *the final values* from the old concentrates it was found necessary to grind *them*."

The extraction of the *final values* would suit a chimera ruminating in a vacuum. You extract the metals, not the *values*, which are within the province of the accountant, not the metallurgist. The man that can grind *values*, could embrace a quadratic equation. Were there several kinds of concentrate; otherwise, why the plural?

12. "The Standard tables affording a *very* fair rough concentration, but making a *very* poor separation of *middlings* and *slimes*."

That wearisome *very*. Here it is contradictory, for a fair rough concentration is a better thing (clumsy as it is) than a *very* fair rough, etc. The reader can have no idea of the poverty of the separation, not knowing the standard of the writer in this regard; therefore, *very poor* conveys not one whit more than *poor*. Were there many kinds of middling and slime?

13. "The total cost of the treatment, including the *values* left in the *tails*, does not *materially* exceed $5 per ton."

Values may be left in *tails*, but gold and silver remain in a 'tailing' even after skillful milling. Moreover, the gold and silver escaping in the tailing do not constitute even *values*, using the term as it is used in a mining camp. The fact that it is a 'tailing,' that is, the final residue from a milling process, indicates that it has no commercial value at the time and place mentioned. This is an example of the contradictions into which that stupid word *values* will lead. *Materially* is immaterial; it conveys nothing.

14. "Such treatment of a silver-ore." "The areas are more or less removed from the present areas of zinc-ores." Why the hyphen after silver and zinc?

15. "By the economical grinding *which* is obtained with tube-mills, such *ores* as those *at* the Waihi mine will be treated mostly in the form of slime."

Which should be *that*, because the clause following defines the particular kind of grinding. Why *ores* in the plural? Does the Waihi mine produce several kinds of ore? Are the ores *at* the mine or *in* it or *of* it?

16. "Experiments are now under way with a view *of* doing the entire treatment on the filter."

It is correct to write *with a view to* and *in view of*, as is done by the same writer a few lines lower in the sentence beginning: "Especially in view *of* the fact that—"

17. "It can be reduced by about 24 per cent., viz.:— to 17 per cent."

Per cent, according to the style of the Institute, is written without a period, for it has ceased to be an abbreviation. We no longer say *per centum*. Similarly *viz* requires no period after it. Both the colon and the dash are not required; either will suffice.

18. "Charcoal, whether added at the beginning or *towards* the end of the roast, fails, etc. (Roasts *Nos.* 3 and 4.)"

The *s* in *towards* might well be omitted, as is done in a previous quotation (No. 4.) from the same source. In *Nos.* the *s* is an obvious error; never pluralize an abbreviation.

FROM THE INSTITUTION.

1. "The personal equation was certainly as important as the system of sampling *which* had been followed."

Which should be *that*, the clause is definitive; in this case reference is made to a particular system that had been followed. *Which* is non-defining and should be attached to clauses that do not limit the antecedent.

2. "In one mine two small blocks of quartz actually produced nearly as many ounces as they were calculated to have *dwt.*"

A careless bit of editing. The abbreviation is without excuse.

3. "But that was a *very* exceptional case, and in considering the *proposition one* must bear in mind what was usually *met with*."

A thing is *exceptional* or it is not; it cannot be more or less, very, or somewhat exceptional. Similarly a thing is *unique* or it is not. When in doubt, omit *very*. *Proposition* is a vulgarism that is done to death by people less educated than the members of the Institution, therefore these will do well to abstain from the use of it. In this case *problem* would serve; in other cases *proposition* is used variously as a synonym for proposal, scheme, plan, or undertaking. As to what is to be borne in mind in this case, must depend upon the particular person and not a nebulous *one*. In any event it is a nice question whether a supposititious *one* can bear in his mind anything so uncomfortable as a *proposition* when in the act of encountering a mysterious something. *Met with* in technology is rank rubbish.

4. "There are the fickle *hanging-wall* and partings to be studied and the amount of waste *rock that* is likely to fall and *water down* the mine *values*."

The wall hangs or overhangs; it is an adjective and requires no hyphen; foot-wall does. *That* is correct, which is unusual. "Water *down* the mine *values*" is a good example of sloppy writing. Do you water *up* anything? Does the writer intend to use a hose and wash the fine gold into the winze? Of course, you can do almost anything to the *value*, for it is an attribute without means of self-defence, it is neither tangible nor sensible. The writer meant that the waste (*rock* is redundant, it could not be *hay*) falling from the hanging wall is likely to decrease the assay-value of the ore.

5. In regard to hyphenation, we agree with an authority that "hyphens are regrettable necessities," and in ordinary literature it is possible to avoid the use of them, but in technical writing it will be found that many words are so linked in a single meaning that hyphenation is imperative. The degree of intimacy between words is expressed in three ways, namely, by their being written separately, as compounds with a hyphen, and as compounds without a hyphen. Thus *ore deposit* conveys two separate ideas, and we can speak of the *ore* and of the *deposit*, neither being essential to the other. In *ore-shoot*, we have a closer intimacy; the *shoot* necessarily consists of *ore;* it is only rarely that we write of cutting the *shoot* or searching for the *shoot*, the word ore being then understood. Finally, in *orebody* we have an example of a true compound, for one single idea is conveyed; it refers to the mass of ore regarded as a whole. We do not drive a cross-cut to find the *body*, but we do perform such work to intercept the *shoot*, although usually we would call it the *ore-shoot*, while there would be no hesitation in planning a cross-cut to ascertain the extent of the *deposit*.

Apparently the Institution sets small store by consistency in the use of hyphens. We find *mill bins*, *low grade roof*, *filter press treatment*, *throttle valve*, and *furnace bottom*, in all of which a necessary hyphen is omitted. In *low-grade roof* and *filter-press treatment* the error is inexcusable. On the other hand, there is a hyphen in "best-equipped properties," which is right, but in strong contrast to the omissions noted.

6. "A ½ in. *mesh* screen."

This looks sadly disjointed, and it is incorrect also. *Mesh* here is used wrongly, despite the efforts at standardization of screens, in which matter the Institution has done excellent service. *Mesh* refers to the number of apertures per linear inch; in this case it is a screen with half-inch apertures. The phrase should be written "a half-inch screen," or "a screen with half-inch openings."

7. "That ore-body had a *very* peculiar shape. It was like a cucumber more than anything else. It had *planes* in it which did not carry *values*. *One* could get samples *which* assayed 15 oz. and in a few *ft.* get no *values* at all."

The *very* is redundant; *very peculiar* expresses no more than *peculiar* unless the writer gives his notions of peculiar shape in an orebody. Such notions would be peculiar. A plane is a flat surface; it cannot carry ore *in* it; as the value of an ore is an attribute, it is conceivable that an attribute was contained within a geometrical term, but as it stands the sentence is non-sense. The writer probably means that the orebody was traversed by partings or fractures, along which ore was distributed in an erratic manner. The pestilent indefinite pronoun *one* appears in this paragrah, and we have *which* where *that* is required by grammar. Then we get an unreasonable abbreviation of feet into *ft.*; and finally there is a repetition of *values*. For once, we are pleased that the engineer got no *values;* the next time we hope he will get some *ore* or *gold* or something that is tangible.

8. In one paragraph "The delivery of water is estimated to have varied from 1,400 to 1,200 *gallons* per minute." And in the next: "The amount of water has lately increased to about 600 *galls.* per minute." Consistency is a jewel. The usual abbreviation of gallon is *gal.*, is it not?

9. "The result from the three sides *are* considered sufficient for the estimation of tonnages and values."

Are is a slip; but why the plural in *tonnages* and *values?* Does it sound more imposing? It is an extravagance that marks the careless writer.

10. "The *lode stuff* consisted of quartz in which are lumps of galena, *pyrites* and arsenopyrite."

Lode-stuff should be hyphenated; the intimacy of idea between them requires such joining. Why arsenopyrite in the singular and *pyrites* in the plural? *Pyrites* is a trade term; *pyrite* is the name of the mineral composed of iron sulphide.

11. "*Gneisses* and crystalline *schists* are the country rocks *met with*."

Why the plural? Were there several kinds of gneiss and schist? And did they come forth to greet the

writer? Apart from the inanity of this particular preposition-verb, it is an error of style to end a sentence with a preposition.

12. "The natives extract gold in *very* paying quantities."

The *very* is not required. An ore *pays* when the yield of metal exceeds the expenditure. The natives probably extracted enough gold to win a handsome profit. Why pluralize quantity? Does it indicate a greater quantity or more of them?

13. "Dissolved in about 50 *cc.* of nitric acid."

The abbreviation stands for cubic centimetre, that is, two separate words; therefore it should be written *c.c.*

14. "If the result were stated in *dwt.-inches.*"

Could anything be more ungainly than this? If pennyweight is abbreviated, why not inches? What excuse is there for a period within a word?

15. "The mine samples from the same *locations* gave 6.83 dwt."

Here *locations* is a colloquialism; either 'places' or 'spots' would be better. In mining, a 'location' is a claim that has been deliminated by pegs or monuments, according to law. Here the reference is to various places in the same mine.

16. "And if *one* knew what it was worth in gross *one* could tell what it would be worth net if *one* knew enough of metallurgy."

Here again is that mock-modest indefinite pronoun. Whatever "one knew of metallurgy" the particular one that wrote this ought to know that such hazy talk is bad technical writing.

17. "Of course, it was *very* necessary to do sampling and to do it *very* well."

The weary iteration of that silly little *very!* Compare the strength of the sentence when written without the *very*, thus: "It was necessary to sample and to do it well."

18. "A block of ore is considered as being developed or "*in sight*" when it has three sides exposed."

The Institution has formally anathemized 'ore in sight'; most properly. Why then permit the use of it in its own transactions? Of course, the double quotation marks might suggest an apology, but it would have been easy to substitute 'in reserve;' furthermore, the double 'quote' is used in the same bulletin to indicate a term that is admissible but not regular, as in "clean up." This affords an example of the usefulness of the single 'quote' to indicate uncommon terms, leaving the double marks for actual quotations. Thus 'clean-up' would indicate that the word was colloquial or local or unusual in some other way, while "clean-up" would mean that it was quoted from another man or some preceding statement.

Apart from the fun of it, I have undertaken to make these criticisms in order to call attention to the desirability of standardization in technical writing, by agreement as to certain spellings and usages. I close with my compliments to the editors in New York and London, and the assurance of my most profound esteem.

SINCE magnesia is the most refractory of the commonly occurring oxides, it is surprising that it is not more widely employed for the construction of vessels capable of withstanding high temperatures. Up to the present, however, ordinary calcined magnesia has been found none too well suited for this purpose. Magnesia bricks, crucibles, etc., of nearly all makes require great care in handling, and it is particularly necessary in furnace work to heat them evenly and slowly, otherwise fracture occurs.

Electricity in Iron and Steel Metallurgy.

There are those who look forward to an electrical method of producing iron and steel. If any practical system of this nature for converting iron-ore into pig-iron or steel could be introduced, using the stored-up powers of Nature instead of burning carbonaceous fuel, the revolution in practice would be great. Probably more than one hundred million tons of coal, equal to about one-seventh of the world's total output, are used annually in the smelting of iron, to say nothing of the further large quantities employed in the subsequent working of iron and steel into more finished form. Where water-power and suitable iron ore can be found together, no doubt, satisfactory electrical smelting practice will be developed, but this can only come slowly.

Pioneer work is being done in Sweden, France, and Canada, in electrical smelting for the production of steel, but unless water-power can be obtained at economical rates it would seem that the application of this system must remain very limited; that other sources of power should be used at present appears to be out of the question from an economical point of view. Moreover, the electric furnace does not purify steel more than other furnaces not specially adapted to that purpose. Bad steel can be produced by it as easily as by the ordinary processes. Some of us know how often the old type of crucible-steel melting, so largely practiced in Sheffield, has been threatened with extermination, but more material is now produced in this way than ever before. The electrical system has in this older method, notwithstanding its extraordinary wastefulness, a competitor that will not soon be annihilated.

An important question in connection with electric furnaces is, whether they can ensure uniformity of temperature. It is well known that they are apt to produce steel which is much colder at the top of the molten bath than underneath; this is, of course, objectionable. Of the many failures with electric furnaces we hear little; it would be interesting to know more about them. I say this in no disparagement of a 'young' process, but to prevent the uninitiated being dazzled by the mere term 'electric.'

It is stated that the efficiency of the electric furnace is already comparatively high, say 50%, but under present conditions it would still be more expensive to develop heat, at any temperature within the range of a coal-fired furnace, by electricity than by coal—that is, if electricity has to be generated by steam-power, even with plant of the highest efficiency.

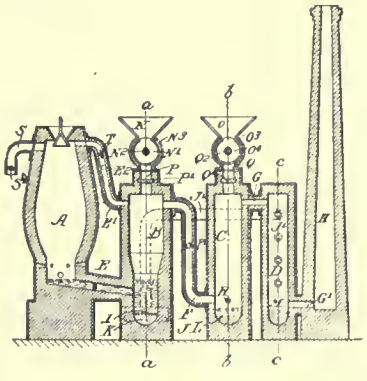
The electric furnace has a range of temperature of about twice that of the ordinary steel furnace, so that it will extend up to about 3,000° C. Reactions which take place within certain limits of temperature as now practiced may be reversed at the higher range made available by the electric furnace.—R. A. Hadfield.

THE greatest care is necessary in the design, construction, and maintenance of a condenser system to keep it free from air leakage. The leaks are inward, therefore invisible, and hard to locate. The application of two or three coats of paint on clean surfaces will eliminate many of the leaks in exhaust-pipe lines, but there still remain several places for air leaks which are not so easy to remedy. The stuffing-boxes on the rods and exhaust-valve stems of the low-pressure cylinder are apt to leak. This trouble, however, can easily be eliminated by using double metallic packing on both rods and valve stems, and piping the steam from the receiver to the space between the two sets of packing, thereby forming a steam seal on the rod.

MINING AND METALLURGICAL PATENTS.

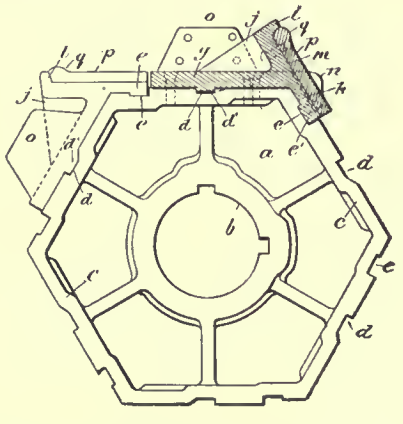
Specially Reported for the MINING AND SCIENTIFIC PRESS.

PROCESS OF OBTAINING METALS FROM SULPHIDES.—No. 844,452; Thomas J. Heskett, Brunswick, Victoria, Australia.



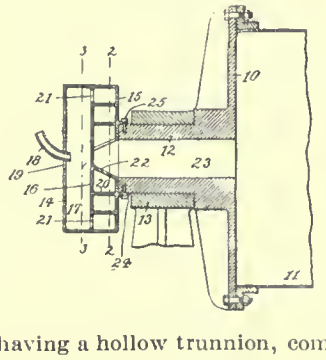
The process of obtaining metals from sulphides, which consists in oxidizing and desulphurizing the melted ores in an oxidizing-chamber, precipitating the unoxidizable metals and collecting them in the bottom of the chamber, passing oxides of the metals and the sulphurous-acid gas in a highly heated condition into a reducing-chamber, there bringing the oxides and sulphides into contact with a reducing material, collecting the less volatile metals at the bottom of the reducing-chamber, passing the more volatile metals to condensing-chambers, and there precipitating them in the order of their condensation.

UPPER TUMBLER FOR DREDGES AND THE LIKE.—No. 845,795; Samuel L. G. Knox, Milwaukee, Wis., assignor to The Bucyrus Company, South Milwaukee, Wis., a Corporation of Wisconsin.



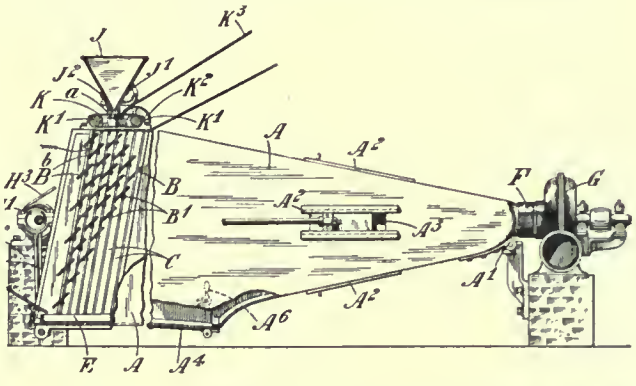
A tumbler for bucket-chains, comprising a polygonal drum, a wear-plate on each face to engage the bucket-chain, and a transverse shouldered engagement between the wear-plates and the drum-faces to resist the tangential strain of the chain.

FEEDING DEVICE FOR BALL-MILLS.—No. 845,992; Max F. Abbé, New York City.



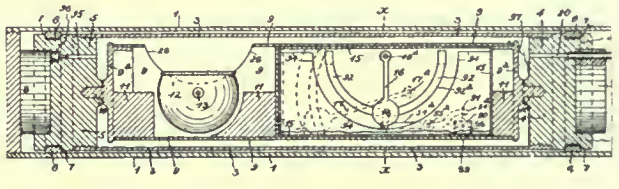
A ball-mill having a hollow trunnion, combined with an exterior cylindrical casing composed of a perforated outer wall, an inner wall, an intermediate perforated partition, a feed-chamber between outer wall and partition, a spiral conveyor between partition and inner wall, said conveyor having a flaring central convolute that opens directly into the outer end of the hollow trunnion, and means for coupling the casing to said trunnion.

SEPARATION OF METALS FROM THEIR ORES.—No. 844,620; Richard E. Saunders, London, England.



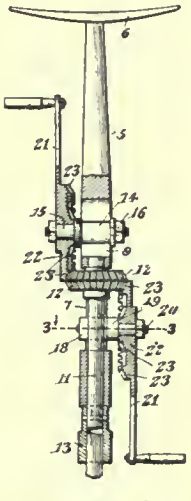
In apparatus for the separation of the metalliferous constituents of ore from gangue, the combination of a casing, an exhaust-fan flexibly connected to one end of said casing, a hinged support for that end of the casing, means for vibrating the other end of the casing, regulatable openings in the casing, adjustable baffles within the casing, and a hopper for feeding crushed ore to the baffles, and an inclined tray extending from the front of one compartment to the other.

INSTRUMENT FOR SURVEYING BORE-HOLES.—No. 845,875; Percy E. Lewis, Johannesburg, Transvaal, assignor of one-fourth to Luther Cyril Franck, Johannesburg, Transvaal.



In an instrument for surveying bore-holes, the combination of an indicator, a casing inclosing the same, means for fixing the indicator and means for changing the pressure of the air or gas in the casing to actuate the means for fixing the indicator.

MINING-DRILL.—No. 845,898; Jasper N. Rickles, Altoona, Alabama.



In a drill of the character described, the combination with a supporting-frame, of a shaft journaled therein, said frame having a longitudinally-disposed slot at one side of the shaft, a bracket slidable on the frame and extending over the shaft, fastening means for the bracket passing through the slot, a gear mounted on the shaft, and a gear mounted on the bracket intermeshing with the gear of the shaft.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The rock from Grants Pass, Ore., marked R. T., is Rhyolite.

THE specimens from C. S., of Oakland, supposed to be Topaz, have not been received.

The two specimens from Los Angeles marked H. N. S. are crystallized brown Garnet and massive white Gypsum.

The pink platy mineral in serpentine, sent by D. F. C., of Redding, Cal., is a chlorite, probably Kammerite, a variety of Penninite.

The powder from Barkerville, B. C., marked F. T., is earthy Limonite, or brown ochre. The value would depend on its purity, situation, *et cetera*.

The specimens from Ely, Nev., marked E. S. D., are: No. 1, Garnet rock; No. 2, serpentinized rock containing Pyrite; No. 3, Granite; No. 4, Epidote; No. 5, Garnet.

The soft white mass from Dayton, Nev., marked C. G. T., is from a deposit of fine silica and clay, and contains a little carbonate of lime. It may have Gypsum veins traversing it, but the deposit would not grade into Gypsum.

A. B. C., of Battle Mountain, Nev., sends: No. 1, an impure greasy Talc, or Serpentine; No. 2, glassy Pitchstone, or Obsidian, with feldspar crystals; No. 3, Andesite, with glassy feldspars, black Hornblende and Biotite visible in the dense groundmass.

The rocks from Chilpancingo, Mex., marked E. E. N., are: No. 1, Mica-schist; No. 2, Gneiss; No. 3, Mica-schist; No. 4, Pegmatite; No. 5, Schist; No. 6, altered volcanic, probably Rhyolite; No. 7, carbonaceous Shale; No. 8, Quartz-porphyry; No. 9, altered Schist; No. 10, 11, and 12, altered volcanics, probably Rhyolite.

TANTALUM, in Western Australia, was first discovered in 1894, when the rare mineral stibio-tantalite (tantalate and niobate of antimony) was identified in the tin washes of the Greenbushes tinfield, near Bunbury. In 1900 tantalite (tantalate of iron) was discovered in the concentrates at the same place, and shortly afterward large deposits of mangano-tantalite (niobate and tantalate of manganese) were found on the Wodgina tinfield. Wodgina is situated on the Pilbarra goldfield, about 160 miles inland from Port Headland. The introduction of the Siemens & Halske tantalum light furnished a market for the mineral, and in 1905 over 70 tons, valued at £8,925, were exported. This ore contains from 68 to 70% metallic tantalum. The market fell away toward the end of the year, and at present there is no official market obtainable for tantalum ores. Although it is popularly supposed that the only use for tantalum is in the manufacture of filaments for electric lights, this is by no means the case, for tantalum possesses properties that render it an important factor in steel alloys. Tantalum is a hard gray metal, somewhat heavier than iron, and is markedly ductile. At the same time, when hammered, it becomes harder than the hardest steel, and has even been suggested as a substitute for diamonds in diamond-drilling. Only a very small percentage of tantalum is required in these alloys. It is believed that Krupps are experimenting in this matter, and that they, or some other German firm, are making every effort to 'corner' the Wodgina fields.—*Electrical Engineer.*

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

A valid location of a placer claim may be made where there has been an actual discovery of gold upon each of several claims located. And where it appeared in addition to this that such claims were situated near other lands presenting the same surface indications, which at the date of the location of the claims in dispute, were known to be valuable for the placer gold which they had contained; and where it appeared from the evidence of expert miners that the indications, together with the relative location, were sufficient to justify the expenditure of money in their explorations, with the reasonable expectation that, when developed, they would be found valuable as placer mining claims.

Lange *v.* Robinson, 148 Fed. 799.

No inference of negligence on the part of a mining company can be drawn from the fact of an accident; neither can liability be based on defective machinery or appliances, that had no connection whatever with a subsequent and different accident causing the death of a miner.

Leonard *v.* Miami Min. Co., 148 Fed. 827.

Where a person makes a valid mining location, he need not keep actual possession of the claim, but his right of possession will continue until he in fact abandons or forfeits it by failure to do the work required by law. The burden of proving a forfeiture or abandonment in such case is upon the party asserting it. Such a forfeiture can only be established by clear and convincing proof of the locator's failure to perform the labor required by the statute, and the burden rests upon the party asserting such failure, and this is a question of fact.

Gear *v.* Ford, (Cal.) 88 Pac. 600.

Where the original locator of a mining claim suspended work for four years, and an adverse location was then made, money expended by the first locator in employing watchmen for the premises, was not a compliance with the statute requiring not less than $100 worth of work to be performed or improvements made during each year. But where the locator did work in good faith for the purpose of developing the mines, in strict compliance with the statute, a court is not justified in substituting its own judgment as to the wisdom and expediency of the method employed in the development, in place of the owner's.

Gear *v.* Ford, (Cal.) 88 Pac. 600.

A real estate broker found a person who took an option on the purchase of certain mining property. The owner of the property died before the option expired, and was therefore never closed. The administrator of the deceased owner, after the expiration of the option, sold the property to the same person, at the same price. It was held that the broker could not recover his commission.

Crowe *v.* Trickey, 27 Sup. Ct. 275.

The owner of lands in his life time executed a mining lease and the lessee took possession. In a suit for partition by the heirs of the deceased lessor, it was claimed by one heir that the lessee was in possession of a certain portion of the property not included in the lease. It was held that a rule could not issue against the lessee for the purpose of construing the lease and requiring him to appear and show cause why a writ could not be issued requiring him to deliver possession of the property in dispute.

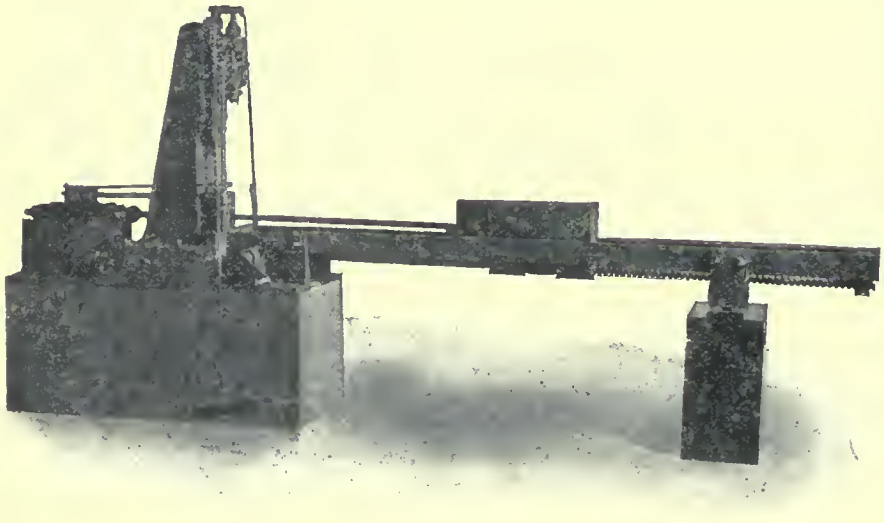
Mounts *v.* Mounts (W. Va.), 56 S. E. 358.

An election by the grantee of a patent for a lode-mining claim to abandon rights acquired under the Act of 1866 could not be assumed from the fact that the patent, in addition to granting such rights, also purported to grant all that would have been acquired by a location under the Act of 1872.

East Central &c. Min. Co. *v.* Central Min. Co., 27 Sup. Ct. 258.

Hammer-Drills.

The increased use of hammer-drills throughout the country has created a demand for a drill-sharpener that will forge and sharpen drills from the blank bar up to eight feet long. The improved Ajax drill-sharpener, A 86 size, illustrated herewith, is designed for sharpening four-wing bits for both hammer and piston drilling-machines, and will sharpen hand-steel as well. It is claimed by the manufacturer, T. H. Proske, of Denver, that the four-wing bits, as made with this machine, will give better results than the rosette, or 6, 8, or more cutting-edge bits ordinarily used in hammer-drills. This machine weighs 2,500 lb., and can be operated with ease by one man. It is specially adapted for use on mines employing a limited number of drills, whether hand or machine. The construction of the improved Ajax is simple, and consists of the main bed-frame to which is attached the dollie or upsetting hammer, and upon which rests the frame for the upright or swedging hammer; this bed also forms an anvil-base for the anvil-die. The take-up screw, for shifting the tail-block back and forth for the different lengths of drills, is journaled into this, and is operated by a crank and a pair of bevel gears, within easy reach of the operator. The tail-block for holding the shank of the drill, while being upset with the dollie, is supported by rollers that travel inside of two pieces of channel-steel which, at their outer end, are supported by a concrete pillar as shown. It will be seen that the working parts of this machine are very few, and they are all contained within and upon the main bed-frame, which is placed upon a solid concrete pillar. The D 24 size machine is the same as the A 86, except that it is made much stronger, being built in proportion to the size of its hammers. This machine is for making both four-wing and chisel-bits from 1½ to 4 in. or more in diameter, and is made in lengths to sharpen drills from 18 in. to 15 ft. Special long machines can be made for drills of any length up to 50 ft. long.



Ajax Drill-Sharpener.

Commercial Paragraphs.

COMPRESSED AIR MACHINERY CO., of San Francisco, report that they have shipped a Word Bros. drill-sharpener to Cranberry, Conn., also one to Loomis, Washington.

VICTOR M. BRASCHI & CO., of Mexico City, has opened a branch at Torreon, Coahuila, in charge of Chas. F. Parker. This is due to the firm's increasing business in the mining machinery required for northern Mexico.

THE DENVER ENGINEERING WORKS CO. has moved its Salt Lake City office from 416 Dooly Block to 205 Atlas Block. The steadily increasing business, under the able management of L. G. E. Bignell, has necessitated more roomy quarters.

BRODERICK & BASCOM ROPE CO., St. Louis, Mo., makers of the famous Powersteel wire-rope and aerial wire-rope tramways, will move their New York office on May 1, from 19 Murray St. to 76 Warren St. Their business in New York has increased so much that they find it necessary to seek larger quarters. C. A. Dunlavy is their Eastern manager.

L. S. PIERCE, 1650 Champa St., Denver, the manufacturer of the Pierce amalgamator, has received the following letter from Robeson & Carter, lessees, Smuggler-Union mine, Telluride, Colo.: "We take pleasure in testifying that we have used the Pierce amalgamators for the past 11 months in the Smuggler mill of 60 stamps of the Smuggler-Union Mining Co., which has been leased by us. The pulp passes through the Pierce amalgamator directly after leaving the plates. During the above named period we saved in the Pierce amalgamator 4,764 oz. bullion, averaging in value $14 per oz. We can strongly recommend their use to persons having ore of a similar character to treat." The amount saved is $66,696 in eleven months, below their plates and quicksilver traps.

Trade Treatises.

THE COLORADO ASSAYING & REFINING CO., of Denver, sends us a little book on determining metals in ores.

THE PACIFIC HIGH EXPLOSIVE CO., of Oakland, Cal., issues a pamphlet describing their Trojan powder.

THE JEFFREY MANUFACTURING CO. of Columbus, Ohio, has issued two bulletins, B and C, describing coal and ash-handling machinery for power plants. They are illustrated by photographs of plants in which these machines are used.

THE FORT WAYNE ELECTRIC WORKS, of Fort Wayne, Ind., has sent us Bulletins No. 1087, 1089, and 1090, describing the Wood systems of direct-current arc-lighting, standard direct-current switchboard panels, and standard alternating-current switchboard panels for single-phase circuits, and various electrical appliances. The bulletins are well arranged, and contain many illustrations and valuable working-drawings for wiring electrical circuits and switchboards. Accompanying the bulletins is an instruction book for the Fort Wayne series A. C. arc systems, and an index to Bulletins No. 1001 to 1089.

A. VAN DER NAILLEN JR., for 25 years a civil engineer of San Francisco, and at present manager of the Van der Naillen School of Engineering, established since 1864, and who several years ago was Commissioner of Board of Public Works, in an interview recently said, in part: "Although the late calamity has brought great loss and distress to many, it has also brought great benefit to many of the working class, and especially to young men who had some knowledge in either civil, electrical, or mining engineering, surveying, draughting, etc." He stated "never before have we seen large posters on the walls of San Francisco, or firms advertising for draughtsmen, wages no object. Our institution, which was re-opened in Oakland shortly after the fire, was almost transformed from an educational institution into an employment office, as the demands came in so rapidly for help in all engineering branches, not only for graduates, but for men who only knew something about electrical work, surveying, drawing, assaying, etc. Many of these calls were from the interior towns. Since April 24 I have sent out nearly 160 students, many of whom had hardly been with me more than several months. Our enrollment list shows over 200 students, yet a visit to our school at the present time would scarcely show an attendance of more than 40, and these prefer to finish their course, or I could place them also."

Editorial.

RECENT violent breaks in the prices of stocks on Wall Street have been imputed to various causes besides the increasing stringency of the money market in Europe and America. It is due largely to the colossal gambling of a few unscrupulous men, whose operations tend to become a constant menace to the stability of our financial institutions, whether they be banks, trust companies, insurance corporations, or railroads. Men of poor judgment and great daring are in control of forces, the momentum of which is becoming intensified as wealth grows. The performances of Jay Gould and Fisk, a generation ago, are being reproduced on a bigger scale.

SOME of our readers will have received a circular inviting them to subscribe to some oil stock in an Eastern State. Among other statements was one asserting that the Jamaica earthquake had increased the flow of oil from wells in northern Texas and Louisiana, by reason of a favorable disturbance among the subterranean strata. This is a geological myth. But no scrap of half-knowledge is too flimsy to serve the purpose of promoters.

AT THIS TIME the State Mining Bureau of California and the similar departments in other States are sending statistical blanks to the persons and companies that produce mineral substances. The information thus obtained is regarded as confidential and is used only in estimating the total production of the county or State. The managers of mines and smelters ought to reply to these requests for information in the spirit with which they are sent, namely, to afford information useful to many and injurious to none.

OUR CONTEMPORARY, *The Iron Age*, refers to the waste in trade literature, in the form of catalogues and descriptive matter, that is never read, nor even examined, by a large portion of those to whom it is sent. There is also a great deal of waste in the imitation technical periodicals that some machinery houses publish for the specific purpose of doing their own advertising. Not much of this stuff is effective. Busy men never read it. Those who have the responsibility of buying machinery are content to read one or two technical papers of the highest character, and if the machinery man wants to arrest his attention, it can be done on the regular advertising pages of such periodicals, which are carefully perused, and in which the distinction between the write-up of the manufacturer and the testimony of the engineer is carefully maintained.

SUCH a break-down of railroad transport as we have seen lately in California by reason of floods, emphasizes the neglect of our rivers as arteries of traffic. There

was a time when the Sacramento did notable service as an avenue of trade, but owing to the neglect of this and other waterways, through lack of maintenance of the levees and insufficient dredging, the commerce of the State is crippled each time the rainfall happens to be excessive. This loss of service is due mainly to the railroad companies, the policy of which is to have the rivers useless for navigation, thereby strengthening their hold on the business of transportation. In many countries, such as England and Germany, the river systems play a notable part in the traffic of the interior and a useful check is thereby maintained against the exactions of the railroads and the congestion of traffic. If San Francisco in particular and California in general are occasionally paralyzed by the temporary disruption of the highways of commerce, it is due to a short-sighted policy and the corrupting hold of the railroad companies. In the same way, despite the chronic interruption to railroad communication with Los Angeles, the steamboat service is not used as much as it might be, because it is not as good as it ought to be, for the sufficient reason that any attempt to make it an effective competitor of the railroads, would be followed by vigorous action on the part of those in control of the transportation system of the State.

Mining Engineering.

THE growth of mining as an engineering problem is made manifest in these days by the magnitude of the ore reserves in some of the copper mines of the West. There was a time, twenty years ago—or even ten—when anyone who spoke of a million tons of ore 'in sight' was regarded as an ignoramus or a knave, for in those days such statements were not true, and they appeared only in the irresponsible descriptions of a flamboyant prospectus or in the careless talk of a middleman intoxicated by the exuberance of his own scheming. Other times, other facts. Many mines can now show, blocked out and ready to stope, more than the apochryphal million tons of a by-gone promoter's dream. But, as if to suggest that we have done with the loose talk of an earlier day, we no longer say that the ore is 'in sight,' which, manifestly, it is *not* until in the bins, but we label it 'in reserve,' or 'blocked out,' or 'ready for stoping,' all of which are phrases that keep alongside the reality. They indicate that the irregular mass of ore or the tabular body of it between the walls of a vein is exposed on two, three, or even four sides, sufficiently at least to afford conclusive evidence as to the tonnage available. It is on the amount thus assured that the engineering operations are based, and it is because that amount is so large in many modern mines that it has become possible to devise comprehensive schemes of exploitation and reduction. For instance, in the mines of the Nevada Consolidated Copper Co. there is blocked out no less than twenty-two million (22,000,000) tons of ore, of an average copper content of 2.31 per cent, from which an average recovery of 33 pounds of copper per ton is practically certain. This ore occurs in two separate and disconnected masses, the orebody in the Ruth mine being estimated at 6,000,000 tons of 2.6 per cent copper ore. In concentrating by water the loss is expected to be 25 per cent, or 13 pounds per ton of ore, the further loss by smelting (and converting) being estimated at 14 pounds per ton of concentrate, on a concentration of seven into one; thus the total loss is 15 pounds and the estimated recovery is 37 pounds of copper per ton. The other orebody, in the Copper Flat mine, is estimated at 16,000,000 tons of ore averaging 2.2 per cent. In working this ore the loss in concentrating will be 11 pounds per ton of ore, and in smelting (and converting) 18 pounds per ton of concentrate. The concentration will be in the ratio of nine to one; therefore the total loss is estimated at 18 pounds and the recovery at 31 pounds of copper per ton. By working two tons of Copper Flat ore and one of Ruth ore, the average yield will be 33 pounds per ton. The two orebodies are of entirely different shape and will be mined by different systems. That in the Ruth has an average width of about 200 feet; it has been developed for a length of about 1,000 feet and goes down to a depth of about 580 feet below the surface. Of this 580 feet the first 180 feet below the surface has been leached and is valueless. The orebody dips at an angle of about 40°. On the other hand, the Copper Flat orebody is a flat deposit, about 900 feet wide by 1,100 feet long and 200 feet thick. The cap at the thinnest point is 25 feet deep and at its thickest it is 150 feet, that is, the orebody is nearly horizontal and does not conform to the surface contour. This cap will be stripped by steam-shovel and the ore itself will be worked by this system at a total cost for mining and development of 30 cents per ton. The Ruth orebody will be worked by the caving system at a total cost, for mining and development, of 90 cents per ton. Mining two tons of Copper Flat steam-shovel ore to one ton of Ruth caved ore makes the total cost, including all development work, of 50 cents per ton. The concentrating and smelting plant now under way is designed to have a capacity of 4,500 tons of ore per 24 hours. This means the smelting of about 550 tons of concentrate per day. These facts are given because they are interesting and for no other reason; most of them have been stated before in other publications, but with less exactness.

The orebodies occur in a zone of impregnation, limited in vertical extent. How far it goes, remains yet to be proved. This is the largest tonnage of ore available in any one mining property, as far as we know, with the exception of Rio Tinto, which is said to be capable of producing a million tons per annum (the present rate of output) for a hundred years. In the Transvaal there are mines with as much as ten million tons of ore assured, for example, in the Simmer & Jack and the Robinson Deep, and this is why methods on the Rand have been developed to so high a degree of efficiency. We have mentioned the great mine at Ely, in Nevada, for the reason that its true character as a low-grade proposition was recognized by several experienced mining engineers, who then went to work in thorough fashion to test the size of it, expecting that either it would be proved too small for the

large scheme of operations required to secure a low working cost, or it would be demonstrated to afford the means for bringing such an enterprise to successful fruition, that is, commercial success. Fortunately, chemical activity and geological structure had inter-acted with sufficient intensity to produce an ore measure of such extraordinary dimensions, although of humble tenor, as to give Mark L. Requa, F. W. Bradley, J. H. Mackenzie, and J. Parke Channing the material upon which to base a plan of mining and metallurgical operations on a tremendous scale. Total costs can be brought to seven cents per pound of copper produced, because a comprehensive scheme can be applied by the aid of the most elaborate machinery, and this in turn can be purchased freely because the security for it exists in the mine. After all, the first requisite for good engineering is the stuff to operate upon, and that is exactly why mining engineering so often lacks the perfection or the completeness of other branches of the science. Is it any wonder that a manager should be careless over the saving of five cents per ton in his working cost when the assay-value of his ore fluctuates by five dollars? His energies are so fully occupied in finding the richest ore that he is bound to subordinate the question of a minimum cost. But give him the stuff to work upon and a reasonable margin in the way of contents, so that he knows he is to deal with a product of a certain kind; then indeed he can suit his methods to his ore and the scale of his operations to his tonnage. That is mining engineering.

TIME WAS when tellurides were regarded as the indication of rich veins of a non-persistent character. In Transylvania, in New Zealand, in the Boulder and La Plata counties in Colorado, in Shasta and Calaveras counties, California, there were numerous occurrences of telluride ore, which were satisfactory as far as they went, but that was not as deep as gold-bearing quartz of other kinds. Cripple Creek and Kalgoorlie proved that tellurides could go deep enough to make magnificent mines and today profitable ore is being broken in these districts between 1,500 and 1,900 feet, with signs of impoverishment at the bottom levels. The matter is of interest in relation to the ore deposits of Tonopah and Goldfield, where gold exists in combination with tellurium, as well as in native form. Apart from the fact that these minerals are not confined to the upper portion of gold veins, there is geological evidence to prove that tellurides may be formed at a depth of several thousand feet below the surface. At Cripple Creek, according to Waldemar Lindgren, the deposition was largely in the nature of fissure-filling and it was not a deep-seated process; there the tellurides occur in crystalline form. At Kalgoorlie, the tellurides are massive and associated with tourmaline, magnetite, and albite, in such a way as to indicate deposition far below the surface. The general evidence goes to prove that no generalization can be based on the presence of tellurides and that persistence in depth is contingent upon structural conditions and the intensity of the thermal activity to which is due the precipitation of metallic ore.

By the Way.

A recent issue of *Nature* contains some interesting observations on the distribution of radium. It says:

When considering the influence of radium on earth history, it is generally assumed that the radium detected everywhere in the surface materials of the earth is an original constituent of the igneous rock. A recent study of the matter has led J. Jolly to a different view, as there seems to be difficulties in the way of accepting the original or primary nature of the radium in rocks. The original nature of the radium cannot be maintained without at the same time assuming the presence of the associated uranium to make good the radioactive decay. If such uranium existed, difficulties would arise from the facts of solvent denudation. The ocean receives the dissolved rock materials, and even assuming geological time as only a very few million years, according to this explanation the quantity of radium now in the ocean should be much greater than has been observed. If the river supply of dissolved rock materials had been sustained for only 20,000,000 years, sea-salt should possess a richness twenty-five times as great as the ascertained amount. In making this statement it is assumed that the radioactive substances are removed from the land along with other mineral matter, and that along with the radium brought into river water on the break-up of rock minerals the postulated uranium is also carried to the ocean. R. J. Strutt has estimated that the radium in sea-salt is 0.15×10^{12} gram per gram. From this there must be in the ocean about 8×10^{9} grams. From Boltwood's experiments, to maintain this quantity of radium in the ocean there must be brought into it annually 1.78×10^{6} grams of radium. Taking the accepted figures for the total volume of river water and the dissolved matter therein which annually enter the ocean, and assuming that the matter in solution possesses the mean radium content of the igneous rock, it is found that only 10^{4} grams should enter the ocean annually in the waste of the land. This is not nearly what is required to maintain the oceanic radium at its approximate present value.

If the associated uranium enters along with the radium there would be in 800,000 years an accumulation of uranium in the ocean sufficient to account for the existing amount of radium; but evidently this period is too short geologically. For these reasons the author seeks to explain the presence of radium in other ways. The simplest explanation is that there is no associated uranium generally distributed throughout the surface materials of the earth. Exception, of course, must be made to the orebodies and thermal springs, and to certain igneous masses which contain uranium. The radium cannot come from volcanic sources, nor can it reach the surface as ores in general do by means of fissure veins. By a process of exclusion the author thinks that he is justified in considering the possibility that the radium is picked up by the earth in its motion through space. The probable source of it is the sun, and there are arguments in support of this view besides that of exclusion. The radium is fairly uniformly distributed over the earth's surface, and it would be expected that the more impervious mineral substances would show the least amount, as has been found to be the case by Strutt. There appears to be no improbability that matter in minute quantities might reach us from the sun, and here we are observing the most minute traces. If the observations are correct as to the velocities of solar ejections, it would take but a few days to bring solar matter into the orbit of the earth. Sun-spot weather action may also be involved, as well as the phenomena of atmospheric radioactivity.

Personal.

THOS. B. STEARNS is at New York.

ERNEST L. ADKINS is assayer at Mullan, Idaho.

GUSTAVE SCHRADER is at Sutter Creek, California.

NORMAN C. STINES is examining mines in Lower California.

W. C. NESBITT is with the Yankee Con. Mining Co. at Eureka, Utah.

W. H. MCDOWELL is with the Traylor Engineering Co. at Kimberly, Nevada.

E. S. SCHRADER, lately with the Bald Butte Mining Co., is at Helena, Montana.

WILLIAM FORSTNER has been examining mines in Siskiyou county, California.

A. C. DE JONGH is at Telluride, Colo. He will go to Houghton, Mich., shortly.

D. E. BIGELOW is consulting engineer with Bewick, Moreing & Co., at Melbourne.

DUNCAN TURNER is employed in the mill of the Tonopah Mining Co. at Millers, Nevada.

WILLIS LAWRENCE is superintendent at the Picacho Basin mines, at Yuma, Arizona.

RAYMOND A. FULLER is assayer with the Penn Chemical Works at Campo Seco, California.

GODFREY D. DOVETON has returned to Denver from a four months' engagement in Mexico.

R. M. BAGG, JR., is temporarily employed with the Portland Gold Mining Co. at Cripple Creek.

J. W. MERCER is in San Francisco, on his return from examining mines in southern California.

W. B. ROUNTREE is now smelter superintendent for the Mountain Copper Co. at Martinez, California.

AUGUSTINE LAWRENCE, lately with the Mariposa Commercial & Mining Co., is now in San Francisco.

ARTHUR GOODALL, manager of the Fremont Con. Mining Co., of Amador City, is visiting San Francisco.

WOOLSEY MCA. JOHNSON is metallurgical engineer for the Tri-Bullion Smelting & Development Co., of Chicago.

FRANK ROBINS is at the nitrate mines in Death Valley, being consulting engineer for the Pacific Nitrate Syndicate.

SEWALL TRUAX has lately been appointed manager of the Grenadeña Mining Co. at Santa Barbara, in Chihuahua, Mexico.

WILLIAM A. HEYWOOD left London on March 6 for a two years' engagement with the Spassky Copper Co. at Akmolinsk, Siberia.

C. L. NEWCOMB, JR., has been appointed manager of the Western office of the Platt Iron Works Co., with offices in the Monadnock Bdg., San Francisco.

D. P. MITCHELL, lately manager of the Oroya-Brownhill mine at Kalgoorlie, is now general manager of the Melbourne office of Bewick, Moreing & Co.

H. A. PARKER has returned to Los Angeles after spending six months examining mines in Arizona; he has now joined the staff of the Blaisdell Company.

EDWIN C. ECKEL has resigned from the U. S. Geological Survey to go into general practice as expert in cement material. His office will be at Washington.

E. M. MCILVAIN, formerly president of the Bethlehem Steel Co., has been elected president and general manager of the Robins Conveying Belt Co., Park Row Bdg., New York.

E. G. DEWALD has resigned as manager of the Western office of the Platt Iron Works Co. and will return to Dayton, where he will be manager of the water-wheel department of the same company.

T. A. JAGGAR, JR., of the Massachusetts Institute of Technology, accompanied by ARTHUR EAKLE, of the University of California, will go to the Aleutian islands, leaving San Francisco on April 20.

PHILIP ARGALL has completed his engagement as consulting metallurgist to the Golden Cycle Mining Co. and is now busy designing two plants for the treatment of ores at mines in the Cripple Creek district.

J. B. FLEMING, well-known as the designer of the Detroit Copper Mining Co.'s concentrator, at Morenci, Arizona, and also of the Silver King mill at Park City, Utah, is now associated with the Joshua Hendy Iron Works, San Francisco.

H. E. NELSON, who has been superintendent of construction for the Golden Cycle mill at Colorado City, has resigned to take charge of the construction work of the new mill of Stratton's Independence at Victor, in the Cripple Creek district.

W. E. DEFTY who has been general manager for two years for the Mina Juarez, in Sonora, now resigns that position, but holds his connection with the company as its consulting engineer. Mr. Defty desires to devote more time to other branches of his profession.

ALLIS-CHALMERS CO. state that for some time past the Smuggler Union Mining Co., of Telluride, Colorado, has been operating a No. 5 K Gates ore-breaker, driven by an Allis-Chalmers motor, in one of its tunnels, for the reduction of ore underground to a convenient form for handling, before it is lifted to the surface. This device has answered the demands put upon it so adequately that the Smuggler Union Mining Co. has recently ordered an additional crusher, a No. 4 Gates type K machine, to be used for the same purpose as the older equipment, and to be driven also by an Allis-Chalmers 20-h.p. induction-motor of standard design.

Mining Summary.

ALASKA.

Some good specimens of ore are coming from the mine at Auk bay, owned by William Winn. A tunnel is being driven on the vein, and the lode is uniform in size.——Some fine bornite ore is being brought from the ridge bordering on the north fork of the Kuskokwin river. The vein is from 18 to 36 in. wide, with the pay-streak from 3 to 15 in. wide, while the gangue is quartz.—— The 20-stamp mill of the Big Hurrah mine, near Solomon, is running steadily.

ARIZONA.

COCHISE COUNTY.

The Bisbee miners have been given a raise in wages, which is the second advance within five months. Without any demand on the part of the miners, a statement was issued by the Copper Queen Con., the Calumet & Arizona, Superior & Pittsburg, Shattuck-Arizona, Denn-Arizona, and American-Saginaw companies that owing to the rise in the price of copper since the scale of wages went into effect on November 7, the following scale would become effective April 1: Miners and earmen, $4 per day; shaftsmen, timbermen, pumpmen, and cagers, $4.50; mule-drivers and firemen, $4; first-motion hoist engineers, $5.50; second-motion hoist engineers and dinky engineers, $5 per day. Sawmill men, timber-framers, blacksmiths and helpers, hand-tool sharpeners, carpenters and helpers, machinists and helpers, boiler-makers and helpers, all get an advance of 25c. per day over the old rate. It is the intention that this scale shall be maintained until there is a material drop in the price of copper. The increase in rates is also to be shared by the men connected with the smelters of the Copper Queen and Calumet & Arizona companies, at Douglas. Considering everything, Bisbee is one of the best mining camps in America, as the mines are large producers, wages are good, and the workmen are surrounded by desirable conditions and means of intellectual improvement and healthful recreation.

This recalls the various prices paid to labor since mining began in Bisbee. In 1885, the wages were $3.50 per day. In 1887 copper dropped to 8c. per lb. and the miners agreed to work for $3, which they did for some time before the wage was placed at $3.50 again. The $3.50 scale continued until 1893, when copper again dropped, and $3 became the pay for a day's work and continued so for about a year, when it was again raised to $3.50. Since 1904 and up to last November, $3.50 was the pay for an eight-hour shift. The eight-hour day was voluntarily given the men in 1902 by the operators and has continued since then.——The tunnel on the Gardner property at Paradise is 130 ft. long, and will be driven 80 ft. further to get under the vertical shaft. The ore carries copper and lead. About 500 ft. of work has been done on the group by the owner, G. I. Gardner.——The Bisbee-Sonora Dev. Co. has absorbed the property of the Paradise Dev. Co., consisting of 10 claims. The new company has also taken over 30 claims in the Warren district, another group of 30 claims in the Paradise district, and other ground, making 70 claims in all.——About 1,700 ft. of work has been done on the Lavery & Hedberg group.

GILA COUNTY.

The Old Dominion mine will, after April 1, pay all miners $4 per day and a proportionate increase for others connected with the mine above ground. The great sulphide strike, a body on the 14th level which has been penetrated to a depth of 73 ft. and yet shows no ending, is occasioning some wonder. The assays run from 22 to 60%. Two crosscuts will soon be run on the 500-ft. level of the Globe Con. Mines Co.'s property.——For a consideration of $285,000, the first payment to be made on May 1, this year, an Eastern syndicate, represented by Sam. W. Osgood, acquired the Collins-Doyle and the Lucky Doyle groups of claims, which are reckoned among the best properties in this district. It is understood that development work will soon begin.

GRAHAM COUNTY.

The Buena Vista group, consisting of seven claims, has been sold to the Arichise Copper Co. for $40,000. This group is situated seven miles north of Solomonville, in the Gila Mtn. A contract to sink a 100-ft. shaft has been let, and ore cars, etc., have been ordered from Los Angeles.

The Chase Creek Copper Co. had made a strike in the long tunnel, which is now in 1,600 ft., giving a depth of 800 ft. About two feet of low-grade ore was cut. I. N. Stevens is the superintendent.——The Comstock shaft of the Gold Belt company is down 100 ft., and will be continued down to the 500-ft. point. Gasoline hoists are used at the Comstock and Gold shafts.

MARICOPA COUNTY.

The Blue Lead mine is shipping ore to the Humboldt smelter and it is said that development work on a large scale will soon commence on this property.

MOHAVE COUNTY.

A party of men from Colorado is engaged in sampling the Bimetal mine, of the Maguire group, south of Kingman. The ore is free-milling gold ore, low in grade, but the deposit is extensive.——The Benedictine company is working a large force of men on the road and in the mines and mill. The Arnold shaft will be sunk.

Map of Arizona.

PIMA COUNTY.

The Keystone copper claims, situated about six miles west of Redington, in the San Pedro valley, have been sold to parties from Butte. Development work will begin immediately, as assessment work has disclosed favorable conditions.

PINAL COUNTY.

D. H. MacKay, acting for Eastern and Los Angeles capitalists, has recently purchased a bond on five claims adjacent to the Silver Queen mine, in the Pioneer mining district in Pinal county. There is great activity in this district at present, owing to the recent rich strike of copper glance in the Queen mine. About ten companies are now at work, their operations covering a radius of about five miles. ——The Mitchell company has recently struck some rich silver ore in a tunnel on its property, which is a mile and a half south of Superior.——The Oregon-Arizona Copper Co. is installing a steam-hoist on its claim half a mile south of the Mitchell property.——The Calumet Con. Copper Co. has 40 claims in this district and is working a good force of men. Men have made a new strike on the south end of the group, having discovered a four-foot vein of copper-glance ore.

CALIFORNIA.

AMADOR COUNTY.

The Bright mine has been pumped out and examined by an engineer with a view to purchase. The result of his sampling has not been made known.——The 2,500-ft. level of the Argonaut is being opened, and promises to be as productive as the 2,400-ft. level, although no ore has been milled from the lower point.——The Wildman company, which has been financially embarrassed for some time, has been forced to stop operations, as the men would work no longer without pay. The top of the shaft has been boarded over and the mine may be permanently abandoned.——The broken compressor at the Keystone has not been repaired, and operations are retarded.

ELDORADO COUNTY.

Engineers are examining the Delevish mine in the Georgetown district, and the property may be re-opened.—— The Pyramid Mining Co., operating in the Shingle Springs district, is advertising for bids for extending the tunnel 500 ft. farther on the vein.——The asbestos deposits in the north end of this county are being examined with a view to using the material in manufacturing enterprises in San Francisco.

KERN COUNTY.

Joseph Weringer of the Greenback Copper mine, near Woody, will commence shipping ore again, after a shutdown of several years, as soon as the roads are in shape for hauling.

The Randsburg district is quite active. The Sunshine mine has been examined with a view to purchase. The shaft is down 410 ft. on this property and the mill and cyanide plant are in good condition, although not running.—— La Crosse mine has been bonded along with a number of other claims, and work has started.——The Alameda mine, just beyond the Johannesburg, will be worked again.

MONO COUNTY.

The long tunnel of the Tanawa Mining Co. will be finished this summer, to a length of 2,800 ft. It has already cut some good veins.——The travertine quarry in this county may be worked again this summer, to furnish ornamental stone for new buildings in San Francisco.——In the Masonic district, the Pittsburg-Liberty company is leasing blocks of ground. A mill will be built in Calavada cañon.

NEVADA COUNTY.

(Special Correspondence).—Attention is again directed to the Washington district on account of a recent strike in the Grey Eagle mine. Free gold has been found in the 14-ft vein, resembling placer nuggets more than gold from a quartz vein. This mine is situated near Maybert, over the ridge from the Arctic mine, which made a strike not long ago.——Some rich specimens have been taken from the 400-ft. tunnel of the Worthley mine, showing free gold and quantities of sulphides. This mine is situated near the Giant King mine, on Washington creek.——Flattering reports are coming from the Truckee district, and miners investigating the district assert that the showing there is good.——A strike has been made in the Lincoln mine, situated about one mile east of Nevada City. The shaft is down 60 ft. The rich ore was encountered at the bottom and along a 25-ft. drift to the east. The ore assays $200 per ton and the vein is two feet wide. The Resartus company, which bonded the mine from the owners, John R. Tyrrell and associates, is developing it and intends erecting a complete plant.——The Canada Hill Consolidated mine is again in operation and sinking from the 1,300-ft. level is in progress. Work had to be suspended the first part of last month on account of the flooding of the mine from a cave from the Greenman mine. The shaft was filled with driftwood and debris, the removal of which was accomplished with difficulty. A two-foot lode of fine ore is displayed in the bottom of the shaft. The corporation consists largely of Berkeley men and they have installed upon the property one of the best plants in the district, consisting of a pump and hoist and a compressor. A 10-stamp mill will be erected during the summer.——The Boss mine, near Sweetland, is to be systematically developed. A plant has been erected that is run by electric power and the company is sinking a shaft, which is down 150 ft. and will go to the 600-ft. level as rapidly as possible.——The Ethel mine in the Washington district is to resume operations in two weeks. This is a thoroughly equipped mine and has a promising future. It has been in operation two years and has extensive underground workings and surface improvements.

Nevada City, March 18.

SHASTA COUNTY.

Grading for the Mammoth Copper Co.'s railroad from Central Spur to the Quartz Hill mine will be completed about April 1. From the Quartz Hill mine to the Southern Pacific siding the road will be narrow gauge and bunkers will be built for storing the ore while effecting the transfer. About 360 men are employed at present in this work.—— The Guggenheims will ship 100 tons of ore per day from the Golinsky mine, on which they hold a bond. Holt & Gregg's narrow-gauge railway will be extended from the limestone quarry to this mine, a distance of two miles, the motive power to be furnished by mules.——The new 10-stamp mill at the Brunswick mine has been started and is working satisfactorily. All machinery at the mine and mill is run by electricity. This mine, which is near French Gulch, was sold two years ago to H. D. Lacey, of New York.

TUOLUMNE COUNTY.

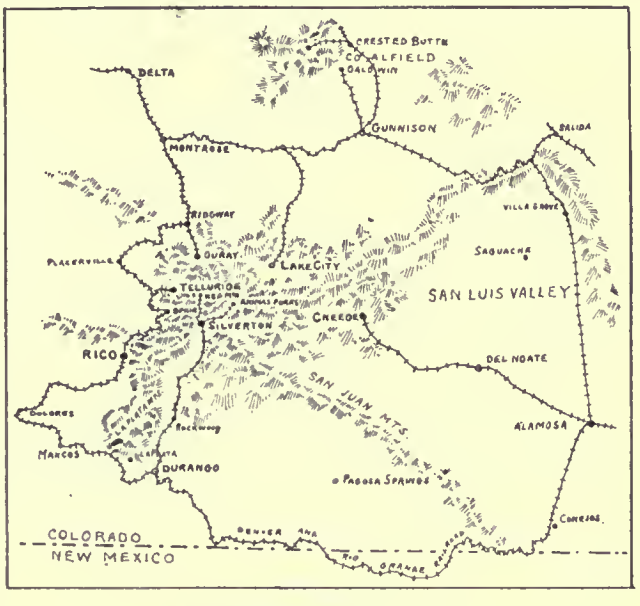
(Special Correspondenee).—Another rich strike has been made in the Soulsby mine, operated by the Bagdad-Chase G. M. Co. A cross-cut from the drift on the 200 level to the hanging wall exposed a body of ore rich in free gold.——It is reported that the Draper M. Co. has been reorganized and that the indebtedness against the Draper mine will be liquidated and operations resumed.——Instructions to resume operations at the Nonpareil mine are daily expected by A. P. Dron, the superintendent.——Development work is going on uninterruptedly at the Preciosa mine, situated eight miles south of Tuolumne, and large bodies of low-grade ore have been opened up. Adit No. 3 is in 200 ft., and cross-cuts show 15 ft. of good ore.——A road two miles long has been built to the Ellen Winton mine, and as soon as the weather permits a stamp-mill and other machinery will be installed on the property.——It is reported that the Bagdad-Chase G. M. Co. proposes to run a cross-cut from the Davidson shaft of the Soulsby mine for the purpose of developing the Wheal Perrin mine, whose vein runs parallel with the Soulsby. Another cross-cut is to be run from a point north of the Pennsylvania shaft to tap the Churchill vein. Many years ago, rich ore was extracted from both the Wheal Perrin and the Churchill, but neither has been worked for a long time, and the old workings have caved in. The proposed cross-cuts will each be about 300 ft. long and will tap the veins several hundred feet below surface. ——The company, composed of Austrian people, which recently bonded the Duffield mine, situated north of Tuolumne, has begun development work with a crew of six men.——The Tennessee Pards G. M. Co. will shortly begin operations at the Esmeralda mine, near Groveland, and Harry Holden will be superintendent. The shaft will be retimbered and development work will then follow.——At the Harvard, 10 more stamps will soon be set in motion, making 40 in all. The winze being sunk from the 800-ft. level is down 115 ft., from which point a drift has been started on the vein. Stoping is in progress on the 500 level, and the extraction of ore from the 700, north and south, will soon be commenced. Seventy-five men are employed.—— An air-compressor has been installed at the Experimental Gulch mine, owned by Conlin Bros., of Columbia, and machine-drills will be used in the cross-cut being driven to tap the vein. The cross-cut will be 1,000 ft. long, and from the point where it taps the vein a drift will be run an additional 1,000 ft. to reach the main shoot, when the face of the adit will be in line with the shaft and 550 ft. below surface. ——The Springfield Deep Gravel mine, the property of the Springfield Tunnel & Dev. Co., will be unwatered at an early date, preparatory to active operations. J. M. Buthenuth is superintendent.

Tuolumne, March 24.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—There is an improvement in the block of ground being worked by Riley & Roehrl on the Sunburst. The orebody has gained in size during the past two weeks from 18 in. to three feet, with assay values increasing from 80 to 175 oz. silver per ton. From 10 to 15 tons are broken daily, and heavy shipments are in order. These lessees are making arrangements to resume work in the winze directly under the stope, and in view of the fact that a 16-in. streak of 600-oz. ore was left in the bottom, previous to the suspension of work, important discoveries should be made in opening the ground by a drift.——Work is being crowded on the Ramsdell mill, and the machinery should be ready inside of 60 days. This plant is to be a modern one. The specifications call for the setting of the crusher, tables, and jigs in cement. In addition, all the floors will be of cement. Hendrle & Bolthoff secured the contract, the price being $22,000.——The Lincoln cross-cut has been advanced 750 ft. and according to surveys the Virginia City vein will be reached within 400 ft. Great results are expected with the cutting of this lode, as from the shaft a heavy production resulted a number of years ago.——Workmen are laying the pipe-line for the 50-ton mill to be erected by the Linn Consolidated M. Co., operating the Mineral Chief on Republican Mtn. According to report, construction of the plant will be started within 30 days. The 10-ton concentrator situated below the portal of the Moline tunnel is running on full time and enough of the finished lead and zinc product is being turned out to insure the payment monthly of one per cent in dividends on all outstanding stock.——The electric plant of the Two American Sisters M. Co. has been started and as a result the 50-ton concentrating plant at the mine is being operated on full time. Wires are being strung throughout the Columbian Mtn. section and power is to be supplied to a number of operators, contracts having already been signed. J. J. White, the resident manager, expects to be employing a force of 40 men within 30 days.——The strike made in the Prince Albert, situated on Columbian Mtn., is improving. The discovery was made in a shaft sunk to a depth of 32 ft., a body of $400-ore having been uncovered. The streak measures two feet in width, and for a distance of 45 ft. the ore-shoot has been found to be continuous. The old workings are being cleaned out and re-timbered, and shipments of about 30 tons per week are being maintained.——Lawson & Co., leasing in the Millington, have encountered a 14-in. streak of $125 silver-lead ore and shipments began this week.—The Dictator continues to ship high-grade ore. A rich streak is being followed and returns in some instances are received in settlement at the rate of 2,200 oz. silver per ton.——Chas. Carlson, lessee of the Lucky Hesperus on Democrat Mtn., is making ready to start shipments. This operator has a streak of ore four inches wide, which mills on an average, 350 oz. silver per ton. A body of quartz is being followed which is worth $40 per ton.——The Krupp M. Co., operating on the Friar Tuck and Bellmont lodes on Saxon Mtn. is working on development. Good headway is being made in driving the adit, and the junction of the two lodes will be reached within 60 days. F. N. Tucker is the manager.——Carson & Swanton, operating a group of claims in East Argentine, have completed the year's assessment work, and a number of important discoveries have been made. Ore is showing in a number of places and now that work is to be resumed on the cross-cut, the holdings should shortly be on the list of producers. These claims are close to the Vidler tunnel property.——Report has it that the Lebanon group of 39 claims, is about to pass to a syndicate of New York capitalists, the consideration being $80,000. In the event of the deal being finally consummated, a milling plant with a capacity of 100 tons will be erected. W. H. Maxton of Georgetown is in charge of operations.——Heavy shipments are being made from the Silver Cloud on Sherman Mtn. A body of smelting-ore is showing in the stope which measures two feet in width, returns of 71% lead and 35 oz. silver per ton being received in settlement.——Shipments are in order from the Mammoth on Brown Mtn. A big body of lead-zinc ore is being followed, the product being shipped to the Kaverne mill at Dumont, where the two metals are separated.——F. A. Maxwell, lessee of the Colorado Central, is making arrangements for shipping several hundred tons of lead-zinc ore to the mills at Idaho Springs. The first lot of 150 tons will go out next week. If the expected saving is made, the output from this property will be increased during the year. The ore is taken from the Sleepy drift, run from the Equator adit, and one of the largest bodies of medium-grade ore in the history of the mine is being stoped, measuring from five to seven feet in width.——Work was resumed this week upon the Clyde group of claims on Leavenworth Mtn. The tunnel is in 500 ft., and is being cleaned out and re-timbered, after which the bore is to be driven to intersect the veins lying ahead. H. K. Miller of Georgetown is the owner.——A lode was intersected on the Annie May cross-cut this week at a distance of 100 ft. from the portal. Two feet of mineralized quartz is showing, through which are running a number of feeders of high-grade ore. E. E. Grubb, the manager, states that a compressor-plant will be installed.——Driving on the Magenta-Turner lode intersected through the Prudential adit, is bringing forth good results. A streak



Map of Southwestern Colorado.

of fair-grade ore was encountered a few days ago which measures eight inches across. Assay-tests show the stuff to be worth $52 per ton in silver and lead. J. J. White is the resident manager.——Work will be resumed in a few days upon the Scott property situated on Republican Mtn. There is at the present time exposed an 18-in. streak of lead ore which is worth $63 per ton. As soon as the ground has been opened for another 100 ft., stoping will be started. John White of Georgetown is the manager.——The Douglass on Douglass Mtn. is shipping a good tonnage of fair-grade ore. The material goes to the mills at Idaho Springs for treatment. The returns show 40% lead, 34% zinc, and 19 oz. silver per ton. L. G. Shepard, the manager, states that the property will be equipped with a 25-ton concentrating plant.

Georgetown, March 22.

DOLORES COUNTY.

At a depth of 185 ft., in the Atlantic Cable mine of the United Rico Mines Co., the porphyry gave way to quartzite, and these is every indication that a new vein will be struck. Rich seams of copper-sulphide ore, of a character never before found in Rico, have been encountered. There is a good deal of trouble from gas in the lower level, and a blower has been installed.——At the Enterprise group, the work, under Murray Lee, is largely of a reclamative nature, old drifts and workings being cleaned out and re-timbered.

LAKE COUNTY.

(Special Correspondence).—The Midland Mining Co., for which F. J. McNair, is the manager, is operating the Hellena Black Cloud and Jane-Eugene lodes in Iowa gulch and shipping one car per week which runs $25 to $45 per

ton. The shaft on the Hellena is now 600 ft. deep and will be sunk 200 ft. deeper later on. At the 650-ft. level they estimate they will strike the contact and will probably encounter water at that depth, necessitating more machinery. Sinking is in what is known as the Weston fault. The company is composed mostly of Pittsburg men.——Activity is being shown in California gulch, more particularly at the Yak tunnel. Four 420-h.p., Stirling Water Tube boilers are being installed at the Yak power-house by the Leadville Light & Power Co.; also electrical apparatus. This company is closely allied to the Yak company.——The A. Y. & Minnie mill is handling the usual amount of material. The Iron Silver is also doing the regular amount of work.

Leadville, March 18.

OURAY COUNTY.

Shipments of rich ore continue from the lease belonging to C. A. Scoope, on the Jonathan property, within the city limits of Ouray. The last carload ran about $20,000.——The Chipeta tunnel is now past the 1,900-ft. mark. At this point the big fracture-zone was encountered and the ground had to be heavily timbered. A raise will now be run to connect with the O. & N. tunnel, a distance of 150 feet.

IDAHO.

BOISE COUNTY.

The Idaho Eastern Railroad is now under construction through the Boise mineral basin to Centerville. As an instance of the impetus that has been given to the development of the district, it is stated that at the McKinley mine, on Jupiter Mtn., a working tunnel will be started to cut the veins at a depth of 1,500 ft. This property has already been opened by prospect-tunnels and open-cuts, and good ore has been removed from depths of 50 or 60 ft. The new railroad will pass within half a mile of the McKinley mine.

IDAHO COUNTY.

It is believed that F. W. Bradley, and associates, who hold a bond on the Buster mine, near Elk City, will purchase the property. The shaft is down 100 ft., and cross-cutting has started from the bottom. J. R. Hutcheson and sons have taken a contract to run a 250-ft. tunnel on the Twin Butte property, near Orogrande, and about 75 ft. has been completed.

NEVADA.

WHITE PINE COUNTY.

A report comes from Boston that the Guggenheim engineers are examining the Giroux property at Ely, with a view to taking control.——It is estimated that over $14,000,000 has been spent by the Cumberland-Ely and Nevada Consolidated Copper companies, in the purchase of properties, development of mines, construction of the Nevada Northern railroad, and the erection of the reduction plant of the Steptoe Valley company. When the reduction plant is completed, the total expenditure of the two companies will have exceeded $20,000,000 which is a pretty large first-cost, before any revenue is derived. The concentrator, to handle 5,000 tons, and the smelter with a daily capacity of 1,500 tons, will be in operation by January, 1908. The largest orebodies thus far opened in the district are in the Ruth and Eureka workings of the Nevada Consolidated, and the best high-grade ore is in the Veteran mine of the Cumberland-Ely group. At the 360-ft. level in the latter mine is a large body of ore averaging from three to six per cent copper.——The raise at the Ely Witch, from the tunnel to the surface, has been completed, having a total length of 260 ft. This will be used as the main shaft in the future.——A new shaft has been started by the Butte & Ely Copper Co., east of the present shaft on the Beehive claim.——About 20 men are employed at the Ely Central property. Two Keystone drills are at work, one being down 325 ft. S. F. Hunt is the superintendent.——Electric lights are being hung at the Steptoe smelter, to enable the steam-shovels, engaged in excavating for the foundations, to work night and day.

NEW MEXICO.

TAOS COUNTY.

The Philadelphia group of four claims was recently sold to a Milwaukee syndicate. B. F. Baker is the manager. The same company purchased the Copper George group of 15 claims adjoining this ground.——The Humboldt shaft, of the Hermosa company, is down 500 ft. From the shaft, a cross-cut is being driven northwest to prospect the granite between the Tourmaline and Honeycomb veins and the Humboldt contact. It is intended to sink to 1,000 ft., and the mine is well equipped with machinery for working at this depth.

MEXICO.

CHIHUAHUA.

Zinc shipments will be started from the station of Baca, being the first ore shipped from the properties of the Almoloya company since the old shipping contract expired in February. The new contract is a good one, and the 10,000 tons now stored at the station will be loaded at once.——Two good strikes have been reported from the Santa Eulalia camp. One was in the Reina de Plata mine, owned by A. McKenzie, and was made at a depth of 340 ft. It is estimated that 50,000 tons of ore are developed, running from 40 to 200 oz. silver per ton. The other strike was made at the 850-ft. level of the Buena Tierra mine of the Santa Eulalia Exploration Co.——Shortage of coal prevents the starting of the new pumps in the Americana mine at Terrazas camp.

NUEVA LEON.

The manager of the German interests owning the Mexican Metals Co., the Peñoles M. & S. Co., and kindred interests in Mexico, has purchased for his companies the Minas Viejas property, near Villaldama, together with the railroad leading from the mines to a point on the National railroad. The new company will take possession immediately, and it looks as though it intends to extend its operations over a larger field than ever before. The property produces zinc ore. F. F. Salisbury is the manager.

SONORA.

Ore has been struck in the lower limestone tunnel of the Sierra de Cobre property at Cananea. The strike was made at the 175-ft. point, and the ore is similar to that in the upper limestone tunnel. Connection will shortly be made between the two tunnels. In the main shaft, the 750-ft. point has been passed and work is continuing toward the 800-ft. point. The property is looking well.——At San Javier, the Wyman Mining Co. is sinking a shaft on the Animas mine. The Ohio-Mexican company is doing development work, with satisfactory results.——It is reported that 50,000 tons of rich silver ore has been developed, ready for stoping, at the Belen property, in the Arizpe district, out of Hermosillo.——The Buena Vista company has cut the vein at a depth of 300 ft.——The Congress mine, west of Carbo, which was sold by L. W. Cowan to an English syndicate, is looking well. The adjoining property, the Rosalia, is also being worked.

Four veins have been discovered on the claims of the International Copper M. Co., in the Carnero Mtn., 30 miles west from Carbo.——At Fundicion, the present terminus of the Alamos extension of the Cananea, Rio Yaqui & Pacific Railway, the Pacific Smelting & Refining Co. is erecting a 1,000-ton reduction plant, to reduce the ores of the Douglas Copper Co., which has properties at El Cobre, in the Bayoreca region; and of the Sonora Con. M. Co., operating the Trigo mines, in the Quiriego region. A narrow-gauge railway is to be built to connect the mines with the reduction plant, which latter will also treat custom ore.——The U. S. A. Mines Syndicate, which owns and operates the Constitucion and Italia mines in the Tortuga region, 25 miles east of Hermosillo, has a carload of mining machinery coming from Denver. The mill will be started May 1, with four Huntington mills in operation. The same corporation has ordered a cyanide plant for the Yeso camp, where another property will be operated under the same management.

It is stated that another 100-ton stack will be built at the Promontorio mines, below Moctezuma. This company has only been producing for about a year, since Illinois capitalists took hold of it. The ore bears copper and silver, and some high-grade ore has been shipped to Douglas and El Paso, but the majority is so low in grade that it was decided to smelt it on the ground.

Special Correspondence.

London.

Mining in Cornwall.—No Increase in Production of Tin.—The Future of Dolcoath.—Persistence of Tin Ore in Depth.—Use of Hammer-Drills.—Scarcity of Labor.—New Flotations.—The Zinc Corporation.—Drop in the Shares.—The Reason for It.—Annual Report of the Mysore.—Progress at the Dolores.

While stockholders in the two or three dividend-paying mines in Cornwall are feeling pleased with themselves over the continued high price of tin, onlookers are wondering why advantage is not taken of the exceptionally favorable circumstances to create larger ore reserves by more extensive development. It is pointed out that while Cornish black tin received the record price of £117 4s. 10d. per ton at the last ticketing, the quantities sold by five of the leading mines, namely, Dolcoath, Carn Brea & Tincroft, Grenville, Levant, and South Crofty, in January and February of this year showed a decrease in each case as compared with the corresponding period of 1906. The reason given for the decreased output of Dolcoath is a slight decrease in the produce of tin per ton of stuff treated, and is expected to be only temporary. The saving point is that Dolcoath has made £3,000 more from a smaller quantity of tin. But Carn Brea is not only lower in output, but also in money value. Basset makes a capital advance, being 14¼ tons to the good and £3,307 in money. Grenville, like Carn Brea, shows a serious decline, being no less than 35½ tons short of the quantity sold in the first four sales of 1906, with £2,015 less. The disastrous series of breakages accounts for a good deal. East Pool has sold nine tons more and realized an additional £2,265. West Kitty has jumped up five tons and placed an additional £1,270 to its credit. Levant, owing to labor difficulty, has fallen off nine tons and has £447 less in cash. At South Crofty the tin has been raised, but the magnetic separator broke down soon after its installation and the management kept back a good proportion of the stuff until it had been readjusted; in fact no tin was sent to the ticketing on February 11. Clitters, like West Kitty, adds five tons and receives £899 more in cash.

In the light of these particulars the manager's remarks at the Dolcoath meeting last week are of general interest. He thought that the proof of the persistence of tin ore in depth might be considered as demonstrated by the extent and richness of the recent discovery in the bottom workings, which were half a mile deep. Referring to the eastern portion of the mine, the manager (Mr. R. Arthur Thomas) said such a large output necessitates ground being opened up to keep the reserves proportionate to the output, and without detailing the various development works in hand, he remarked that on the whole the position in this respect is more assured than it has been for some years past. This portion of the mine is the greatest contributor both in the returns of tin and tin-stuff, while the produce for tin is lower than that of the bottom of the mine. Various developments are in hand, and it is difficult to determine the most important. The most interesting, however, is the work that is being done in opening up the large mass of granite lying between the two lodes to the west of the eastern shaft at the 375-fm. level, and its importance lies in the fact that large profits are expected therefrom. This formation might be described as a brecciated granite with numerous fissures filled with the tin oxide. A large tonnage will be rendered available for working when the developments now in hand are more forward; in all probability at least from 50,000 to 60,000 tons of ore at about 35 lb. tin per ton of stuff. The winze below the 375-fm. level west of the eastern shaft is now down about 10 fm. and a raise over the 400 a little to the west of it have both improved in value and are now producing 60 lb. tin per ton of stuff. Dealing with the question of the working costs per ton Mr. Thomas explained that these have increased consequent upon the higher prices of materials and the increased labor charges, which are higher now than they have been for some time past. A great deal of renovation work has been done at the surface, which is charged to profit and loss account, and in consequence no diminution in the charges can be expected, but a decrease in the cost, especially of dressing, will shortly be secured. The prospect for a reduction in the underground working charges under the conditions obtaining are rather remote, and the manager considers that a solution will lie in the direction of the employment of more mechanical means. Experiments have been made with a hammer-drill, which is virtually the ordinary pneumatic tool, and the results are so satisfactory that their employment is likely, especially if unskilled labor can be employed. There is even now a dearth of skilled miners, and if, as appears the case, the development of the tin mines generally throughout the County are taken seriously in hand, that question is one to be faced; and it would appear that the solution may lie in the direction indicated. Mr. Thomas gave the meeting some particulars as to what was proposed with regard to the utilization of the copper ores left in the upper levels of the mine formerly, when they had no means for the treatment of such complex material. He said the ore they had in view chiefly consists of zinc, copper, and arsenic sulphides in combination with the oxide of tin. The Elmore process extracts the sulphides from the oxides. The oxide of tin is treated in the ordinary method of tin dressing. The sulphides consist of zinc to the extent possibly of 35%, and copper to, say, 4 to 5%. The treatment of this ore presents an interesting problem.

The Cornish labor question will have to be solved in some way if the existing mines mean to make more energetic efforts to benefit by the present opportunity. It is thought that Cornishmen might be brought back from the north of England and south of Wales, while there is talk of importing Italians or Scandinavians, who are excellent workers. The importation of Chinamen is no doubt barred; but the same objections will not apply to 'Dagoes.' This is very well so far as it goes, but the difficulty is in recruiting the old tributer class of miner so essential to the finding and profitable working of tin-bearing ground. The supply of such skilled miners is a matter of first importance to the financial groups responsible for the various new flotations. During the past year it is said 30 Cornish companies were formed with an aggregate capital of £1,184,700 nominal. Among the further flotations in the new year is the Falmouth Consolidated Mines, formed to acquire the Wheal Jane group of mines. Worked in the past in an erratic manner, these properties are said to have paid substantial dividends for many years on the capital employed in them, but with up-to-date plant and under one control greatly improved results are expected. Of the nominal capital of £150,000, £70,000 is set apart for working capital and the general purposes of the company. The Tresavean mine in the Gwennap district, has also been started by a company registered in Glasgow, with a capital of £40,000. When Tresavean was last worked in August, 1885, the output of tin was small. Tin was then £97 against £87 the previous year, 1884. When the mine was at her climax as a copper mine, tin was only £85, so with the present price of metal, Tresavean should be successful. The mine is exceptionally dry and electric power will now

be requisitioned. New Wheal Eliza Consols (St. Austell district) has also been registered, with a capital of £60,000, the promoters being Cornish Tin Properties Ltd. Several of the leading members of Cornish Consols and the Syndicate now owning the Tehidy mineral rights have joined in forming the Cornish Trust. The capital, £100,000, is to be employed in doing mining business generally, and the organization should prove to be an important factor in the development of the mineral resources of the Connty.

It is reported on the market that the anxiety among the shareholders of the Zinc Corporation has not been allayed by the news recently circulated. The proprietors, who have seen their shares as high as 55s., can only now realize at about 28s. They are unable to account for the large amount of selling that has taken place, except on the assumption that there is truth in the rumor that the new plant is a failure. Readers of my correspondence will remember that the Zinc Corporation was formed toward the close of 1905 with a capital of 350,000 shares of £1 each. There were strong local and London boards, the general managers being Bewick, Moreing & Co. The Corporation purchased, approximately, 2,000,000 tons of tailing, containing an estimated value of £10,000,000. For 12 years the Barrier tailings had baffled the metallurgists of the world. Experiments had been tried everywhere without satisfactory results. The Ashcroft process was used at first. Under the old system the Barrier companies were content to save 35 to 40% of the silver, and 56 to 75% of the lead, the zinc passing away with the residue. The Zinc Corporation is understood to be trying the Potter-Carmichael-Bradford process to start with, and to have acquired a large interest in the Potter Sulphide Treatment Co. Mr. Queneau, who was announced as a metallurgical chemist of high attainments and of great experience in the treatment of such ores in the United States, has been removed from the control. The official version of the matter appears to be that this gentleman's services have been invaluable to the company. He is, however, a man who, if anything, aims too high. When he has got his plant and works into such a state that they will give him a 96% return, he would be tempted to undertake their entire reconstruction from floor to roof, if by so doing he could get 97%. This kind of thing, while it appeals to a scientist with considerable force, does not influence in the same way the people that have invested their money, and who are waiting for returns upon it. It has therefore been thought desirable that Mr. Queneau's position should be modified, in order that less of the ideal and more of the real may be infused into the company's program. The change involves no reflection upon Mr. Queneau. In fact, it is rather a tribute to his scientific abitity, which is of a higher standard than the needs of the company require.

The report of the Mysore Gold Mining Co. for 1906, just issued, states that 185,900 tons of quartz were passed through the mills for a yield by amalgamation of 184,163 oz. bar gold, an average of 19 dwt. 19 gr. per ton. In the cyanide department 158,848 tons of tailing were treated, from which 21,755 oz. gold were extracted, an average of 2 dwt. 18 gr. per ton. By amalgamation and cyanidation, together, 208,188 oz. of bar, or 205,918 oz. standard gold were obtained; this realized £809,412, or, after deducting £40,111 paid to the Mysore Government as royalty, a net sum of £769,301. Rents, interest, transfer fees, and rebates on freight increased the income to £775,024. The expenditure chargeable against revenue was £318,924, leaving a profit of £456,100. The three dividends for the year equal 14s. per share, or 140% upon the issued capital, and aggregate £418,674. The authorized capital is now £305,000, in 10s. shares. The underground developments have exceeded in extent, importance, and value those recorded within any similar period in the history of the mine. At Ribblesdale's the workings have now reached a depth of 3,504 ft., and throughout the twelve months the vein at the deepest levels continued wide and rich. The superintendent says: "The developments during 1906 in the bottom of Ribblesdale's have disclosed ore of very good quality, and, seeing that these are the deepest workings on the mine, the outlook in depth on this section is of a very reassuring nature." Referring to the ore-shoot south of Tennant's shaft, the superintendent says: "The new ore-shoot discovered beyond the main shoot in the 1,870-ft. level south of Tennant's shaft, mentioned in last year's report, has opened up exceedingly well, and proved to be continuous at that level for over 400 ft. It still holds forward in the above drift, and has been driven on at

Eastern Australia.

the 1,750, 2,000, 2,120, and 2,240 ft. levels south, and there is every indication that it will not only continue in deeper levels, but will be found to extend to higher ones. As this shoot is uniformly of high grade, it will be seen that a very important and valuable extent of stoping ground has been developed in this part of the mine." A new shaft from surface, named Hancock's, which has reached a depth of 258 ft., is being sunk to facilitate the development of this orebody. Within the past few weeks the vein has entered the shaft, where it is of a promising nature. The deposit is thus proved to exist, both vertically and laterally, to the full extent of the present operations upon it; that is to say, from 250 ft. from surface to the 2,240-ft. level, and for 400 ft. in length. Taken in conjunction with Tennant's main shoot (which maintains its productiveness), this new orebody renders Tennant's section of the property a mine of considerable magnitude in itself.

With regard to the discovery at McTaggart's, the superintendent writes: "In McTaggart's section, where hitherto exploratory work has been attended with little success, a rich body of ore has recently been discovered

south of the shaft, and has been proved for a considerable distance in the two bottom levels, namely, the 1,960 and 2,060-ft. levels, which are farther west than any others previously driven at this end of the property. As to ore reserves, at December 31, 1905, the estimated quantity of payable ore in the mine was 613,000 tons; this has since been increased, after allowing for the 185,900 tons extracted, by 134,000 tons, making at December 31, 1906, 747,000 tons described by the superintendent as profitable. Although the opening up of the mine was temporarily interfered with during the drought, 29,890 ft. of driving, sinking, and rising—being slightly in excess of 1905—were accomplished. The directors are of the opinion that, notwithstanding the past year was one of unparalleled success in connection with the mining developments, there is every reason to anticipate that the current year will be equally satisfactory. The reserves show a substantial increase over those of 1905, and it may be assumed that they will be materially added to during the current twelve months by reason of the discovery at McTaggart's, and in view also of the continued richness of the ore-shoots at Tennant's and Ribblesdale's. About a fortnight ago the news was cabled to London from the mine that Rowse's shaft from the 400-ft. level to surface had been destroyed by fire with head-frames and portions of floors. It is now reported that the fire is extinguished.

Dolores (Mexico) developments continue to prosper. According to the latest cabled news, at the fourth (bottom) level, in the shoot extending from the main workings on the third level, a rich body of ore two feet wide has been struck, assaying $367 per ton, and the rich streak in the vein recently discovered by the San Francisco cross-cut, 330 ft. east of the main workings, has increased to a width of one foot, assaying $438 per ton. The next event awaited is the cutting of the San Francisco vein itself.

Butte, Montana.

Davis-Daly Estates.—Progress of Development.—Important Discoveries in Several Mines.—Green Campbell Co.—Heinze and His Partner.—Dividend From the Snowstorm.—The Iron Mountain Mine.—Troubles of the Raven.—Original Finds Ore on Lower Level.—East Butte Production.

The Davis-Daly Estates Co. is doing a lot of development work on its properties. The long cross-cut going south from the 1,800-ft. station of the Original mine is now 1,500 ft. long. Several veins of good ore have been cut, but they do not apex in Davis-Daly ground. Recently another stringer was cut and it was generally believed that the cross-cut was penetrating the Thomas lode, but the manager says that it will not be reached for a further distance of 100 to 150 ft. The end of the cross-cut is now under Park St., the principal business street of Butte. At the Smokehouse, driving on the vein at the 500 level continues westward and it is expected that good ore will be found within 100 ft. Eastward the drift has encountered a broken and displaced condition of country and some exploration work will be necessary there. Operations at the Smokehouse are expensive, every pound of waste must be hauled away as fast as hoisted out of the mine, which is situated on a small lot in the heart of the business district of Butte. The shaft of the Colorado is down 750 ft. and will be sent to a depth of 1,000. Cross-cutting is also being done at the 500, but the opening is in country-rock. Sinking has been resumed at the Silver King, where the shaft has been straightened and skips put in. At the Mt. Moriah cross-cutting to the vein is in progress. In the west drift of the Smokehouse stringers of copper glance have been found and Mr. Palmer, the manager, is confident that commercial ore will soon be found in that property.

It is reported that the Butte Coalition Co. has cut a big vein in the ground of the Alice Co., north of the Corra mine. At a depth of 2,200 ft. the Coalition ran a cross-cut from the Corra northward. The vein cut is believed to be in the Magna Charta claim; the value of it is not known, but the information is that it is a good one.

It is reported that the North Butte Co. has decided to sink a new shaft on the Berlin claim, and that it will be used as a second working shaft, the one on the Speculator not being of sufficient capacity to mine all the property of the North Butte. This decision was made after the vein in the Berlin was cut by the 1,600 ft. cross-cut from the Jessie mine. At a depth of 1,800 ft. the vein of the Edith May has also been opened. The North Butte Co. has just purchased the Gem millsite, a small claim lying in Silver Bow creek, south of the Margaretha of the Berlin group, paying $50,000 therefor.

The Green Campbell Gold Mining Co., which has stockholders both in the East and West, has suspended operations at its mines in the Silver Star district of Madison county. The company owns a number of claims and several mines from which, many years ago, a great deal of gold was taken. What remains and has been opened comprises several large bodies of low-grade ore, yielding

Montana.

from $2 to $14 per ton, the average being low. A lot of money has been spent developing the property, and about a year ago it was decided to build a concentrating and amalgamating mill, which was recently completed. The company built a good mill but neglected to figure on a water supply, depending on the water taken from the mines. That, however, proved insufficient and instead of treating 100 tons of ore daily, as the company has expected to do with the new mill, it could only take care of about 20 tons. After a short run, it was also discovered that the mill was imperfect, and a shut-down became necessary. Before work can be resumed a water supply must be obtained, and that will cost considerable money, as it must be brought a long way and by means of a pumping plant. Additional machinery for the mill is necessary, and the company is deeply in debt, having a bonded indebtedness of $75,000 and unsecured debts of more than $25,000. The nominal capital is $1,000,000. A reorganization will be necessary.

F. Augustus Heinze and his former banking and business associate, Thomas M. Hodgens, are giving promise of airing a lot of trouble in the courts, and the friends of each predict sensations. Hodgens has already instituted two actions in the courts of Montana and two in New

York. The Montana suits are for an accounting of a stock investment business. One of the suits instituted in New York is for an accounting of a Long Island real estate deal, in which they paid $150,000 for 966 acres of land, now claimed to be worth $1,000,000. The other suit is against the United Copper Co. for an accounting. Hodgens owns 1,300 shares of preferred stock and he charges that during the past year the company has paid a total of $3,450,000 in dividends when as a fact, as he claims, it did not earn to exceed $1,000,000 net. He therefore demands an investigation to ascertain the standing of the company and the source from whence came the surplus put into the dividends.

The Snowstorm Mining Co. has declared another monthly dividend of 3%, which calls for a distribution of $45,000 to the holders of the stock. Equal sums were distributed in dividends in November, February, and March, making a total of $135,000 to date. The manager, W. D. Greenough, has been in New York for several weeks and that fact has given rise again to reports that the Greenoughs may sell their interests in the Snowstorm to Heinze. It is a fact that Mr. Heinze tried to buy the Snowstorm, but they could not agree on a price. The Lewisohns also made an offer for the property. It is also reported that the Greenoughs have secured absolute control of the stock of the old Iron Mountain Mining Co., whose property lies just east of the Cœur d'Alene and north of De Borgia, Mont. At one time the Iron Mountain was a more famous producer of silver and lead than the Bunker Hill & Sullivan, but for more than eight years no work was done. The old workings consist of one shaft 1,800 ft. deep, and some drifts and cross-cuts. When a law was passed requiring more than one exit to a mine, work was stopped on the Iron Mountain. The ore-body, though rich, is but 350 ft. long, and, the ore having been taken out to so a great depth as 1,800 ft., the owners were in doubt if enough ore could be mined to pay for the driving of an adit that would tap the ore-shoot at a greater depth. Last spring, however, work was started on a long opening which will be driven more than 10,000 ft., and is being pushed ahead at the rate of 10 ft. per day. It will require at least three years to complete the adit.

So far as Butte stockholders and officers of the Raven Co. are concerned, there is little knowledge of what progress is being made toward a reorganization of the company. They claim to be in entire ignorance as to what, if anything, is going on. The hope of the Raven people is that the Amalgamated and Coalition interests may be induced to put their holdings into the company, but, as far as can be learned in Butte, no progress has been made in that direction.——It is reported that the Colusa-Leonard Extension Co. has cut a small vein at a depth of 185 ft. in the shaft, but it carries little value. The vein is about three feet wide and was in the shaft a distance of 50 ft. before it passed out to the south. The Colusa-Leonard made a record in shaft-sinking. Work was started about the first of December and a station is now being cut at the 500-ft. point. When the station is completed sinking will be resumed and the shaft will be put to a depth of 1,000 ft. The Colusa-Leonard lies just east of the property of the Reins Copper Co. The Colusa and Leonard mines are east of the Reins.

The Original Mining Co. has opened some better ore on the lower levels of the Stewart and Original mines and the output has been considerably increased. Nearly a thousand tons of ore are shipped daily to the Butte Reduction works. It is estimated that the March production of copper by the Clark works will be between 1,300,000 and 1,400,000 lb., including the custom ore treated there.——The East Butte Mining Co. has started a cross-cut south from No. 11 shaft and will open the Yankee Boy vein at a depth of 400 ft., probably within a week. The north cross-cut from the same point is being pushed north and will shortly connect with the cross-cut from No. 1 shaft. The latter shaft is now 800 ft. deep, and another station will be cut there. During the past week this company made two shipments of precipitate, which yielded about $14,000 in smelter returns.

Calumet, Michigan.

Approach of Spring.—New Exploratory Work.—Tracing the Baltic Lode.—Activity in Keweenaw County.—Calumet & Hecla Testing Large Tracts.—The Keweenaw Co.—The Medora Amygdaloid.—Diamond-Drilling on the Empire Tract.—The Centennial Equipment.

Present indications are that the spring in the Lake Superior copper country will come in three or four weeks. There are already signs of a break-up, but the snow will not be sufficiently melted to permit of exploratory work for a few weeks. The high price of copper for the past year has placed the mining companies in an excellent position to do an exceptionally large amount of exploratory work and unusual activity along this line is expected.

In Ontonagon county, at the southwestern end of the Michigan copper region, it is expected that there will be considerable work. The Lake Copper Co., which now owns and operates the old Belt property, has found by means of diamond-drill explorations what is believed to be the Baltic amygdaloid bed. A shaft will be started as soon as the ground is in good condition. The top of the lode is near the surface, and, as the overburden is light, no trouble is anticipated in getting the shaft down to the solid rock. There are a number of companies in the vicinity of the Belt mine that may explore for the Baltic lode. The Mass Consolidated Mining Co.'s property is well located and it is believed that the lode exists on its land. The Mass management has also signified its intention of exploring for this lode during the spring. The Adventure property probably contains the dip of the Baltic lode, but the formation could be opened only by means of vertical or very sharply inclined shafts. The St. Mary's Mineral Land Co. owns land adjoining the Lake Co.'s property and the tract undoubtedly carries the continuation of the lode.

In Keweenaw county, which is at the other end of the copper region, the coming summer is expected to witness a great deal of activity. Near the Houghton county line the Allouez and Ahmeek mines are developing into valuable properties, and adjoining the latter on the north is the Mohawk, the most important producer in that vicinity. But beyond the Mohawk, the work which is now in progress, and is contemplated, is largely exploratory in character. The Calumet & Hecla Mining Co. and the Keweenaw Copper Co. are the most important concerns operating in that district. The Calumet & Hecla is working through subsidiary companies, which are developing and exploring a big territory. Immediately north of the Mohawk is the Gratiot, controlled by the Calumet & Hecla. This property, like the Mohawk, is being developed on the Kearsarge amygdaloid. Two shafts are being sunk, but the work has not reached sufficient depth as yet to give an adequate idea of the lode. The Ojibway is developing lands north of the Gratiot; it is a new company, in which the Cole-Hoatson-Ryan people are interested, being largely the same group as that which controls the Keweenaw Copper Co. The Ojibway property was explored with a diamond-drill under the direction of Dr. L. L. Hubbard, of Houghton, former State Geologist and at present

general manager of the St. Mary's Mineral Land Co.'s Challenge, King Philip, and Winona mines. At Delaware, the Calumet & Hecla is working two shafts on the Montreal River lode, an amygdaloid that gave much promise at surface, but the showing in the lowest openings is not so favorable. Another shaft was started not long ago on what is believed to be the northerly extension of the Kearsarge amygdaloid. The showing in this is encouraging.

The Keweenaw Copper Co.'s principal work is at the Mandan location, where a shaft is being opened on the Medora amygdaloid. The representative of the MINING AND SCIENTIFIC PRESS was underground in the mine this week and carefully examined all the openings. The showing is most encouraging. The Medora lode is crossed at some points by fissure veins, and at the points of intersection is greatly enriched. The shaft has reached a depth of 500 ft. and the rock in the bottom is uniformly well charged with copper. There is considerable 'mass' and 'barrel work' at the shaft that was

At the Centennial mine the new steel shaft and rock-house at No. 2 shaft is enclosed, and work on the interior is progressing rapidly. The power-equipment for No. 2 shaft, consisting of a hoisting-engine and high-duty air-compressor, supplementing the power-equipment in service at No. 1 shaft, is well advanced, and will be ready for operation by the time the rock-house is completed.

Goldfield, Nevada.

The Labor Trouble.— A Fight Between Two Organizations.—Mining Operations Hindered.— Scarcity of Supplies.— Probable Settlement of the Quarrel.

The probability of serious disturbances in Goldfield is increasing. A number of incidents contribute to bring about the present situation. The camp is infested by a number of agitators from all directions, and the criminal element of camp hangers-on is strongly in evidence. There are many men who cannot get work and a greater

The Copper Region of Lake Superior.

taken out in the course of development work and a few thousand tons of good milling rock is on the dump. Capt. James Bryant is in charge, the general supervision of the company's work being in the hands of Capt. Thomas Hoatson of Calumet, who is mining director for the Keweenaw company. The Medora shaft has a good surface equipment, consisting of shaft-house, two 150-h.p. boilers, a Lidgerwood hoist, 12-drill compressor, office and dry building, blacksmith-shop, machine-shop, and warehouse.

At a point about four miles north of the Medora shaft the Keeweenaw company is preparing to sink a shaft on the Empire property. This tract has been thoroughly tested with diamond-drills. The new shaft will be sunk on the Montreal River amygdaloid. Three diamond-drill cores of a favorable character have been taken from this formation. The first hole intersected the lode close to the surface; the second core was taken out at a depth of 400 ft., and the third drill-hole penetrated the lode at a depth of 1,300 ft. The Keweenaw company owns such a vast territory, extending nearly 11 miles on the stretch of the formation, that it has abundant room for the development of several large mines, if copper can be found in paying quantity. It will take many years to explore and determine the actual value of all the company's lands. The Mandan property gives indications of providing a good mine, the openings in the Medora shaft having a highly encouraging appearance.

number who are not looking for it. Between the miner and operators there is no trouble or ill-feeling, in fact, the Miners' Union is accused of siding with the operators. The fact is that times are prosperous alike for the miners and operators. Wages in Goldfield are now $5 per day for miners, while at Tonopah the men are far more content, and are only getting $4 per day. The origin of the trouble lies entirely with the agitators and a dispute between the labor organizations. The Industrial Workers of the World, an affiliation of various trades-unions, has tried to act with a high hand, and manage the affairs of the Western Federation of Miners and the Carpenters' Union. This was resented by the latter, and the trouble began. A determined fight is being made by the I. W. W. to prevent the Miners' Union from leaving them. The miners say they do not want their affairs managed by waiters and bartenders. Public sentiment, both among operators and working men, is running high against the I. W. W., though the latter retain a strong hold on the tradesmen by threats. Organized labor in Goldfield is now divided, the consolidated mines are shut down and many stores are closed, but there is no strike. At present it looks as if some little rioting and disorder may occur before any settlement is reached, because the feeling is fiery on both sides. The larger mines have little to lose by a temporary shut-down, and the lessees get an extension of time in case of labor troubles. The scarcity of mining timbers and supplies

had necessitated stopping work on many properties, in fact, the present cessation will be far more serious for the workingmen, who are suffering severely from the high price of supplies, than for the operators, who are awaiting the arrival of material. A depression in mining will be serious for some of the smaller companies, but it will probably eliminate many of the undesirable people and mining schemes, which infest Goldfield, without serious injury to the more stable enterprises. Everyone, miners and operators, clerks and waiters, wish to see these difficulties thrashed out once and for all, so that the mines and the many branches of business rooted in them may again thrive without the uneasiness and lawlessness, which has permeated Goldfield during the last few months.

Toronto, Canada.

A Canadian Department of Mines.—Shipments From Cobalt.—A New Gold District.— A Mass of Silver.— News From Cobalt Mines.— Several Rich Finds.— Smelter and Concentrator.

A bill has been introduced in the Canadian Parliament to create a Department of Mines, which will take over and reorganize the Geological Survey and the Mines branch, extending their scope. The Department will be in charge of a minister of the Crown, and the Geological and Mines branches will each be under a deputy minister. The public lands in Manitoba, Saskatchewan, and Alberta are under Federal jurisdiction, and one of the principal duties of the Department will be the regulation of the mining industry in those Provinces. Mr. Templeman, who represents British Columbia in the cabinet, is slated for the position of Minister of Mines. The Ontario Government has under consideration the construction of a branch of the Temiskaming & Northern Ontario Railway from Cobalt to Sudbury, to open up a rich mineral area. This policy has been steadily urged by the T. & N. O. Ry. commission, which operates the road for the Provincial Government.

Shipments of Cobalt ore for the week ending March 16 were 262 tons from the following mines: Nipissing, 159 tons; Buffalo, 50 tons; O'Brien, 32 tons; and Red Rock, 20 tons.

Dan Mosher, a veteran New Ontario prospector, and Capt. F. W. Coates, arrived in Toronto this week from the Abitibi country north of the Height of Land, where they have been working all winter, and report the discovery of a new goldfield. They found good silver and copper-bearing quartz, and staked 27 claims, on which they have had a gang of men steadily employed on development work for six months. Several shafts have been sunk, and the ore, in addition to other minerals, shows good gold contents. Camp buildings have been erected, and the fame of the new field, which is known as the Mosher Gold Camp, is attracting an influx of prospectors.——Harold P. Davis, of New York, president of the Davis Exploration Co., is seeking to interest Cobalt mining men in the Mines Exposition to be held in New York during April. It is hoped to get a representative exhibit of samples of Cobalt ores, as well as of mining machinery and processes.

A mass of silver was fonnd at the Temiskaming mine, Cobalt, on Mareh 16; it weighs 276 lb., and assays 12,000 oz. per ton. It was taken from the 75-ft. level. At the Empress mine the shaft has reached a depth of 52 ft., the vein having narrowed downward from 6 to 4 ft., the ore, however, being more highly mineralized.—— The Erie-Cobalt shaft has reached the 100-ft. level, and driving is being done westward so as to cross-cut other veins. The shaft is on a 14-in. vein, from which ore is being taken out.—— Silver has been struck on the North Cobalt mine in Bucke township at the 43-ft. level. The vein is calcite, of about 12-in. width, and interspersed with native silver.—— A calcite and slate vein, in alternate layers of about 30-in. width, has been discovered on the Cleveland-Cobalt property, about 16 ft. from the main vein. It carries native silver.—— An Ottawa syndicate, headed by George R. Lyon, has secured five locations just west of the Silver Queen and north of the Cleveland-Cobalt, and will begin development immediately. It is stated that on one of the properties there is a 14-in. vein running 600 oz. silver per ton.——At the Gordon-Cobalt the shaft is down 59 ft., at which depth a good find has been made, the vein being wide and well mineralized. A plant has been ordered comprising a 55-h.p. boiler, 40-h.p. engine, drills, etc.—— The Buffalo mine, second only to the Nipissing as a shipping mine, is working three shafts day and night. The main shaft is down 135 ft., with 400 ft. of drifts at the 70-ft. level, and 100 ft. of cross-cuts at the 130-ft. level, where 120 ft. of driving has been done. Shaft No. 5 has been sunk 97 ft., and is connected with the main shaft at the 85-ft. level by an adit 360 ft. long. No. 5 shaft is sunk on two veins that are being worked, and extensive driving has been done in several directions. The wall-rock in these veins is rich, containing much native silver in leaf form. No. 4 shaft is down 60 ft., and driving has been commenced at that level. An assay of ore taken from the bottom of this shaft showed 5,490 oz. silver per ton. Prospecting shafts have been sunk in several places on the property. T. R. Jones is the superintendent.

The small smelter at Hamilton, Ontario, which was used for some time by the North American Cobalt-Refining Co., composed of Cobalt mine-owners, in conducting experiments previous to constructing a large plant for the treatment of their ore, has been bought by W. G. Tretheway, who has withdrawn from the company. The ore from the Tretheway mine will be treated at Hamilton. The company is letting contracts for the building of a smelter at Thorald, Ontario. The Cobalt Concentrators, Ltd., has closed a contract with the Ore Reduction Co., Ltd., of Toronto, for the building and installation of a concentrating plant at Cobalt, with a capacity of 100 tons of ore per day, the total cost being $35,000. The machinery comprises the new process of dry concentration, by which it is claimed that any ore in the district can be successfully treated, and at least 90% of its value recovered.

Denver, Colorado.

Shortage of Labor.—Exodus to Nevada.—Newhouse Tunnel Stopped. —Long Adits Generally Disappointing.—Work of theGeological Survey.—Pumping at Cripple Creek.—Colorado College Adds to Its Equipment.

The excitement of the present developments in Nevada has had the effect of attracting miners in large numbers from the principal mining camps of Colorado, so that the present supply is hardly equal to the demand. The exodus is most strongly marked from the camps that are essentially prospective in their nature, and many camps that were thriving a few years ago now contain many deserted cabins. Whether, with the present high cost of living, this demand for labor will cause trouble is not yet clear, but so far no marked signs of it have appeared. Wages remain at the level they have maintained for years past and demands for increases have not been made.

After reaching a length of 17,500 ft., the Newhouse tunnel has been stopped. The companies already operating through it produce sufficient to employ its haulage equipment to full capacity and the organizers of the enterprise are now hoping to reap the reward of their expenditure. The water in the district as a whole is slowly being lowered by this adit. Numerous other

adits are under construction or are proposed. Strangely enough, few of them ever cut veins at points where the ore is rich, and as a rule the results of the investment are disappointing to everyone except the owners of mines above the tunnel water-level.

The geology and mineral resources of Colorado have been investigated in the past by the United States Geological Survey, and the results of the investigation have appeared in three monographs, three professional papers, seven bulletins, and ten folios of the geologic atlas, covering the more important mining districts of the State. Besides these many papers have appeared in the annual reports of the Director of the Survey and numerous other papers have dealt in part with Colorado. In addition many sheets of the topographic map have appeared, and many papers have been prepared by the Division of Water Supply & Irrigation. The State has shown itself slow to co-operate with the National Survey and work that otherwise could have been done at half cost or less to the State has been neglected. The best investment the State could possibly make would be to appoint a State Geologist who should have power to co-operate with the United States Survey, and to carry out such investigations himself as are not within the province of the larger organization.

Several properties on the eastern border of the Cripple Creek district have combined in a joint pumping arrangement. In this way the Portland, Strong, and Granite are to be drained by a pump on the Gold Coin mine's 1,200-ft. level. El Paso is contemplating closing down until the new drainage adit shall have reached it and unwatered its lower level.

The department of mining and metallurgy of Colorado College, at Colorado Springs, has added a Féry radiation pyrometer to its equipment and with this addition to its other instruments, is now better equipped for investigations into commercial high temperature problems than any other school west of the Mississippi. The problems developed in the roasting of the telluride ores of Cripple Creek are being studied to determine the temperature most suitable for conducting the roast, and later a study of the heat developed in the converting of copper matte will be made.

Johannesburg, Transvaal.

Satisfactory Output. — Interesting Details of Yields. — Chinese Behaving Better.—Hot Political Contest.—A Diamond Mine Boom.—Good Rainfall.

The returns for January, just published, are satisfactory. In December, 19,115 oz. of reserve gold were included in the output, so the returns for that month were inflated. For January no reserve gold was declared, which makes the total less than for December, but there is an actual increase in the monthly returns of 6,586 oz. The yield for January is therefore a record, and stands at 537,638 oz. Of course, the published output for December of 550,167 is higher on account of the reserve gold.

The Rand advanced in its stamping power last month. There were 50 more stamps at work. Outside districts, however, show a decrease of 10 stamps. During January there were 8,120 stamps at work on the Rand, and 330 in outside districts, making a total of 8,450 for the Transvaal. The Simmer & Jack was the first mine on the list, with an output of 24,419 oz.; the Robinson was second with 22,090 oz.; while the Robinson Deep was third with 20,047 oz. As regards profits, the Robinson establishes a record for the Transvaal, with £60,000. The Simmer & Jack made a profit of £47,078, and the Robinson Deep £40,939.

On January 31, 1907, there were 53,828 coolies available for the mines. Chinese labor for the month remained steady. Very little trouble was experienced from the coolies during January. There were practically no outrages.

Politics and politicians are the chief attractions just now. The combatants have come to close quarters, and the din of the battle is heard on every side. Dignity has been thrown to the winds, and some of the meetings have been as rough as any political meeting ever heard of in America. The epithets being used are somewhat spicy. For instance, in today's paper, one of the upholders of the Het Volk party refers to a leading knight of the Progressives in these words: "I declare that if he has been guilty of making the above statement, he is not only a malicious slanderer, but an unscrupulous liar." A bit warm, is it not? At the meetings on the mines we are hearing men refer to their opponents in anything but choice language. The press is simply full of politics, with comments on the candidates. All their past history, right back to Adam and Eve, is being dragged out for the benefit of the voters. Lurid cartoons and posters are to be seen on every hand. Electioneering agents of both sides are making themselves agreeable to

Map of South Africa.

the voters. People are getting tired, and will be heartily glad when the election is over. In my next letter I hope to be able to write of the newly elected members. Election day is on February 20. All kinds of discussion has taken place as to the granting of a holiday on the 20th. It has been decided not to make it a legal holiday, and the labor leaders are maligning the capitalists for this. No one pays much attention to the labor leaders. It is doubtful whether a single labor candidate will be elected.

The sensation of the week on the Stock Exchange was the phenomenal rise of the stocks of Lion Hill Diamond mine, a venture in the Orange River Colony. Three weeks ago these shares stood at 13 shillings each. Yellow ground was finally discovered by means of boring operations, and when the consulting geologist handed in a favorable report, there was a wild boom, the shares going up as high as £20. Today they stand at £14 10s. per share. Development work is being pushed on, and if the results are at all favorable, it is probable that the shares will go to £50. Quite a rise from 13 shillings!

During the past fortnight the Transvaal has been blessed with heavy rains, the best rainfall we have had for years. All the mine-dams are overflowing, and there is no danger of a scarcity of water for the mills. One or two smaller dams broke away, but no damage was done. In one or two mines there has been a rush of water into the workings, necessitating increased pumping and bailing.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

BRASS is an alloy of copper and zinc, or of copper, zinc, and tin.

ROLLED PLATINUM has a specific gravity of 22; gold, 22 carats fine, 17.49; pure lead, 11.33; pure silver, 10.47.

CLAY is the term applied to those earthy materials occurring in nature whose most prominent property is that of plasticity when wet.

WHEN inexperienced in estimating the amount of gold in the bottom of a pan or horn, a useful thing to remember is that a cent is a piece of gold about 1/32 in. square, and half as thick as a $5 piece.

AS a usual thing, in looking for placer gold, an abundance of quartz pebbles in the gravel is a good indication, especially when accompanied by black sand, garnets, and small, round pebbles of chrome-iron.

MOST of the boulders in ordinary placer ground are waterworn fragments of local rocks, the large proportion of quartz boulders being due to their hardness and ability to resist decomposition and corrasion.

THE distance between the bearings of a line-shaft should not be great enough to permit a deflection of more than 1/100 in. per foot of length; hence the bearings must be closer when the shaft is heavily loaded with pulleys.

THE ordinary gold pan is stamped out of a single piece of charcoal sheet-iron. It is about 16 in. in diameter across the top, and 2¾ in. deep, with flaring sides. Such a pan will hold about 25 lb. of gravel if heaped in the centre, and about 150 pans make a cubic yard.

IN the adjustment of the transit, the level tubes should be parallel to the vernier plate; the line of collimation should be perpendicular to the horizontal axis; the horizontal axis should be parallel to the vernier plate; and the intersection of the cross-hairs should appear in the centre of the field of view.

THE hydraulic elevator can only be used on moderately coarse material, as the diameter of the tube and the force of the lifting jet prevent the passage of very coarse material. Often the gravel is raised by elevators to a height of 30 to 50 ft., or more, and in this way the sluice-boxes can be from one-eighth to a quarter of a mile longer.

AN engine-stage is the division of a railroad to which an engine is limited, and over which it regularly hauls a train. Its length varies from 50 to 200 miles or more, depending on the grades, length of the whole line, and on the distance between points favorable for the situation of shops. The average engine-stage in America is not far from 75 miles.

CLAYS are always of secondary origin and result primarily from the decomposition of other rocks, very frequently from rocks containing feldspar, but there are some rocks which contain no feldspar (such as serpentine), and others with very little (as some gabbros), which, on weathering, produce some of the most plastic clays known.

WATER-WHEELS do not get all the power out of falling water. Undershot-wheels realize only about one-third; breast-wheels about one-half; overshots, from two-thirds to three-quarters; turbines and impact-wheels, from three-quarters to 85%. Large quantities of water under small heads are best utilized by turbines; but above 20-ft. heads, the impact-wheels will be found satisfactory, even up to 2,000-ft. heads.

THE right to use timber growing on an unpatented mining claim is limited to its necessary use *on the claim* for mining purposes. The abuse of this right will not cause a forfeiture of the claim, but will subject the transgressor to a civil action by the Government, and possibly to something more unpleasant. Whether cottonwood is 'timber' may be debatable. As a matter of prudence we would prefer that the judicial determination of this question should be at the expense of the other fellow.

WHEN a mass of rock, as, for instance, granite, is exposed to the weather, minute cracks are formed in it, due to the rock expanding when heated by the sun and contracting when cooled at night, or there may be joint planes formed by the contraction of the rock as it cooled from a molten condition. Into these cracks the rain-water percolates, and, when it freezes, it expands, thereby prying open the fissures or even wedging off fragments of the rock. Plant-roots often supplement the action of the frost. These processes alone may eventually reduce the rock to a mass of small angular fragments, or even to fine sand.

ANY error in the adjustment of a Y-level gives the line of sight a slight angle of elevation or depression, causing a slight error in every reading, proportional to the distance of the rod from the instrument. But the errors being equal for equal distances, and the backsights and the foresights having opposite signs in the calculations, the errors cancel when the distances are equal. Hence, to avoid errors in elevation, each new turning-point should be as nearly as possible at the same distance from the instrument as the point on which the last backsight was taken. For precise reading, the rod should not be more than 400 ft. from the instrument.

A LODE-CLAIM crosses a placer-claim within which there is a water-tunnel. It is sought to get credit as assessment work for the work done in the water-tunnel within that part of the lode-area in conflict with the placer-claim. The water thus developed is carried off the placer to another lode-claim upon which there is a quartz-mill, where the developed water is utilized for milling purposes. It is obvious that work done for the avowed purpose of developing water on the placer within the area common to the first lode-claim and the placer for use elsewhere does not tend to develop the lode-claim within which the work was done or facilitate the extraction of its ore, and this is the test. Without attempting to prejudge the case, we think this is skating on thin ice.

WESTERN AUSTRALIA forms a tableland of moderate elevation surmounted by short and low ridges. Crystalline schists and granites are the principal rocks of which this plateau is constructed. The schists extend with general north-south strike and vertical or steep dip across the whole central part of the State and consist largely of amphibolites, massive or foliated, which have been derived by matamorphism from a basic rock like diorite, gabbro, or diabase. There are also highly altered sedimentary rocks such as quartzites, slates, etc., more rarely limestones. At Kalgoorlie, for example, slates are intimately associated with amphibolites, and on a more extensive scale these altered sediments are developed in the Pilbara district on the northern coast.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Tube-Mill Lining.

The Editor:

Sir—The experience of Mr. A. E. Drucker, in Korea, as given in your issue of November 17, 1906, is interesting. To my mind, the reasons why he obtained such very unsatisfactory results in his ingenious experiment are the following:

(1) His mill is probably too light in construction, thus allowing the lining to 'work.' Any continuous bonding movement in the walls of his mill must gradually break up his lining, which is in one continuous long length.

(2) I think it was a mistake to make the lining in two distinct layers and to cover the tops of the rails.

In reference to my 'honeycomb' linings which he refers to as 'proposed to be used,' I can assure him there is no doubt about the matter, they have actually been in use for over a year, showing over three times the life of imported silex. Nine tube-mills are now running in Waihi with my patent linings.

By dividing up the spaces, as I do, the lining material has not the same chance of working loose as in the method tried by Mr. Drucker. He is quite right in saying that no cement will stand the terrific wear, but it only wears to a certain depth, when it becomes protected by the quartz projecting around it. If Mr. Drucker has a foundry handy I am sure he will find it worth while to try my system, as his only difficulty seems to be in holding the quartz in position and not in the wearing quality of the quartz lining.

H. P. BARRY,

Waihi Gold Mining Co. Ltd., Waihi, New Zealand, February 1.

Tappets and Cams.

The Editor:

Sir—You will confer a kind act on me and other millmen, if you will mention in your paper the annoyance I have had through an order for tappets, cams, and guides.

I ordered the tappets bored for 3¼-in. stems and the cams for a shaft of 5 in. diam. The tappets came bored 3/32 in. less than the stems and the cams ⅛ in. less than the shaft. The foundrymen tell me that this is the present standard system in shaft-measurement. I know that there is such a gauge in cold-rolled shafting, but it is new to me, in regard to mill-stems and cam-shafts, although I have milled off and on for 34 years. I have gained the reputation of being a careful and conscientious man and feel this botch very keenly. Of course, in future, I shall state *actual measurement by rule*, and wish to warn my fellow millmen to do the same.

MILLMAN.

Los Angeles, March 10.

Tufa and Tuff.

The Editor:

Sir—Just a few words in relation to the enclosed clipping from your issue of February 16. "Tufa is a cellular deposit of mineral springs, usually calcareous or silicious. The name is not to be confused with tuff, which is the name given to the finer, fragmental ejectments from the explosive eruptions of volcanoes." Your definition of 'tufa' and its origin is correct. So also as to 'tuff,' except that you do not go far enough to show that tuff can, and is, found in other ways than by the "explosive eruptions of volcanoes." Like eruptive rocks, tuff originates in two ways—first, volcanic ejections, and secondly as a dike material. In Arizona and Mexico, in Cochise county and in the State of Sonora, the source of all lava rock is from fissures and not volcanic or thrown out by violent explosions. The same is true of the tuffs found in the above localities. In Sonora great dikes of porphyritic tuff, rhyolite tuff, etc., exist, and can be traced for miles. Now the point I wish to make is this: That those dikes of tuff, as above classed, are fissure veins filled and formed in a like manner to metalliferous veins, minus the metal. From Cananea southeasterly two or three hundred miles, in a mineral zone several miles wide, many of these tuff veins or dikes are to be seen. They occupy a place in this great mineral belt, and undoubtedly owe their presence to an altering agent contained therein. Their dip is nearly vertical and the strike cross-wise to the trend of the metalliferous veins. That they are part and parcel of the rock in which they exist, there can be no doubt, the parentage and relationship is too evident to permit of question or argument. Porphyritic tuff is found in porphyry, and rhyolitic tuff in rhyolite, and andesitic tuff in andesite, and so on. Again, a vein or dike of black obsidian four feet wide is found. Now you would not say that this had its origin "from explosive eruptions of volcanoes," would you?

On the Train. March 5.

[No, we would not. We would call it a lava or compromise by labeling it tufaceous lava.—Editor.]

The Salton Sea.

The Editor:

Sir—In regard to the popular idea that the Salton Sea has changed the climate: I remember back in '69 in Nevada that there was a wet cycle of years culminating in '74 by the removal of a large part of the town of Eureka, and the drowning of 15 people, by a flood down the cañon. Old-timers in Arizona will testify that about that time grass and water were plentiful in the land, as they have been in the last three years. By the rain records the year '84 was by far the wettest year in the history of this Coast. In '89 I started as helper with a 16-mule team from Phœnix to Wickenburg. It rained. By using much profanity and many buckskin poppers we made eight miles in five days. Then by chaining the mules together so that when one went under the mud the others could pull him out, we miraculously got back to Phœnix without any of the outfit being drowned. I saw it rain more in this part of the country in three months in '96 than it has rained in the whole of the last three years. All the foregoing happened when there was no Salton Sea, which may seem singular to a good many people nowadays.

Only about 75 or 100 miles south of the Sea lies the Gulf of California, a body of water 50 times the area of Salton Sea, with the same conditions of evaporation and distribution of its vapors. Why has the Gulf of California not been deluging the country with floods of water? This would be a very wet country indeed if that Gulf had been dropping 50 times as much water as the imaginations of a great many people have made the Salton Sea to drop. In traveling over an area of 300,000 square miles in Arizona, Nevada, and California, I find the same impression that the Salton Sea is the cause of it, and for aught I know they may have the same idea away over in Texas and up in Oregon, where it rains all the time. The area of Salton Sea is, I suppose, about 1,500 square miles, and I suppose that an evaporation of six or seven feet of its water in the last two years would be a fair estimate, which, if spread out, would cover 10,000 square miles of surface 12 in. deep. Now I think that there has fallen 12 in. of rain in the last two years on the 300,000 square miles of area mentioned above; if so, the

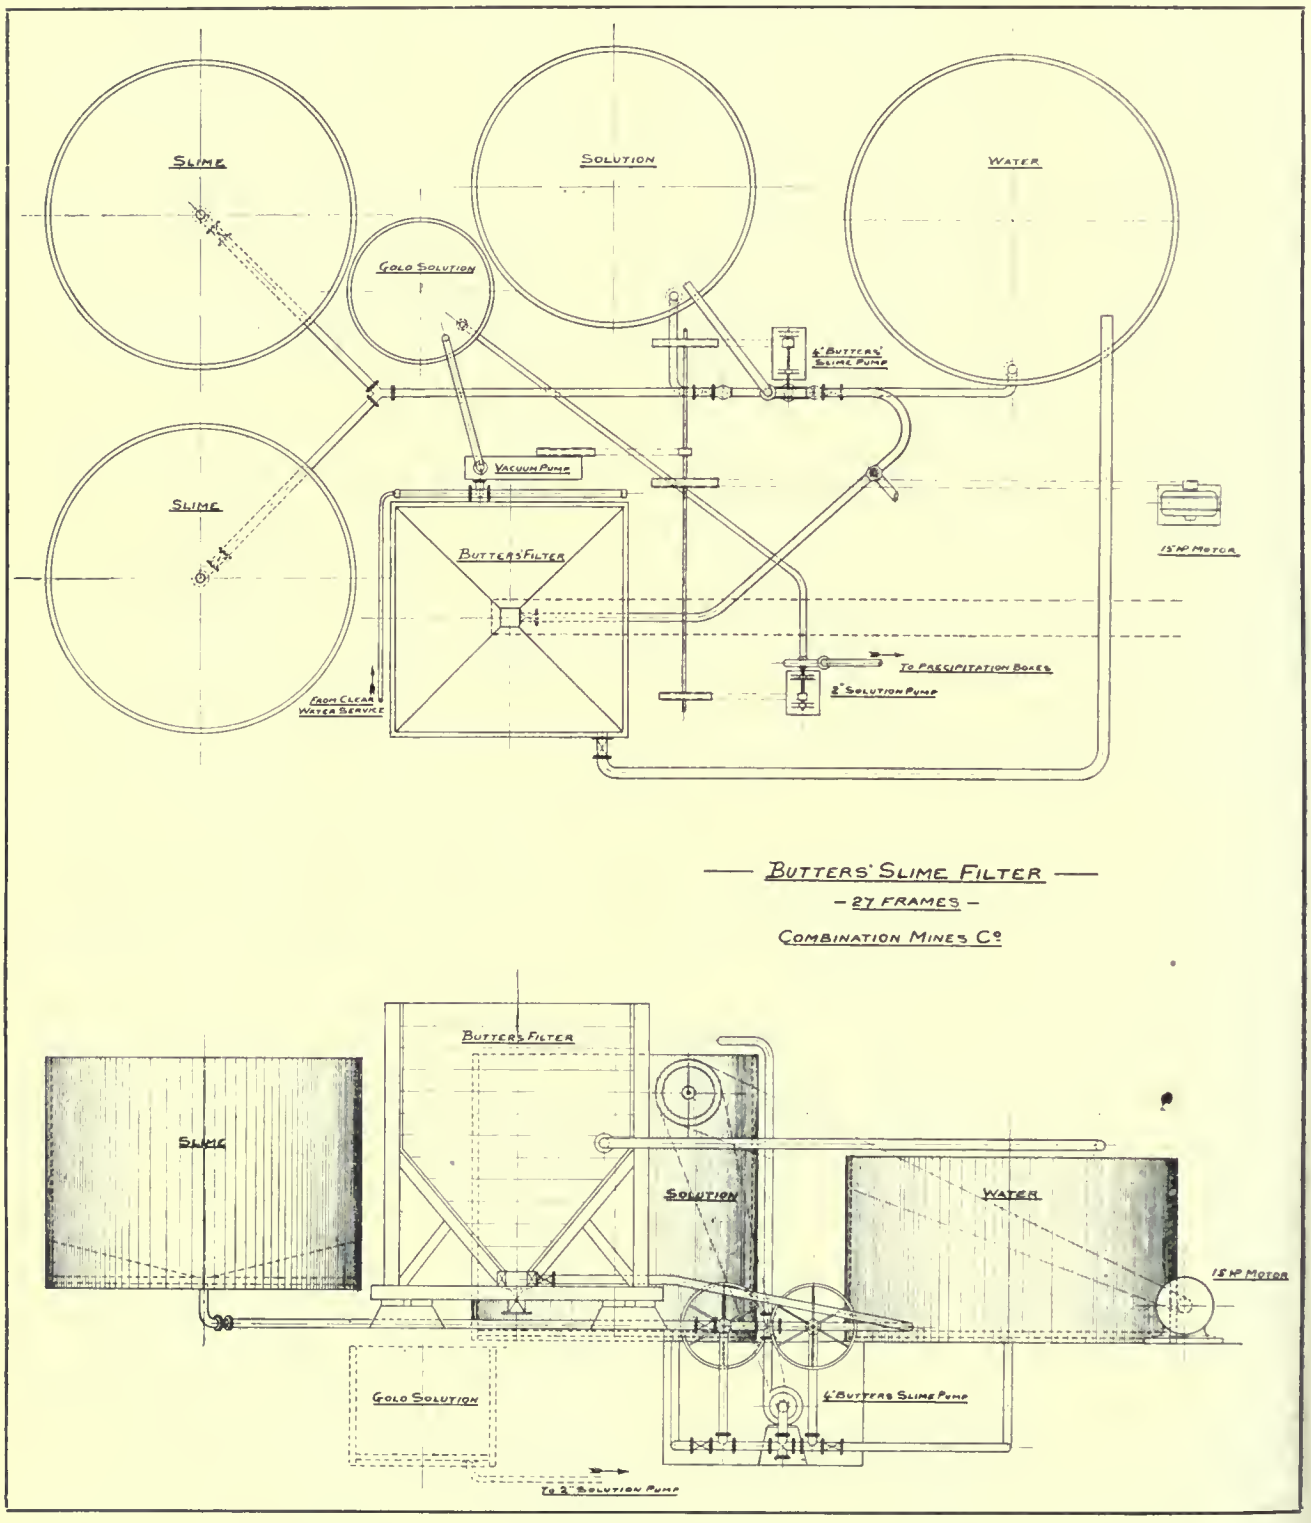
evaporation of Salton Sea would equal only one-thirtieth of the rain which it has been supposed to be furnishing. An increase of only one-thirtieth of the annual rainfall would be so small as to pass unnoticed.

It seems to me that in watching the Salton Sea so intently, we have forgotten about the Gulf of Mexico and the Pacific Ocean, where the rain used to come from.

WM. R. BAILEY.

Needles, March 7.

My error in regard to the number of filter-leaves at Millers was due to the fact that 216 leaves were billed to the company. I presume that it has been found that less leaves will treat their slime. I should perhaps have said that, "a plant designed according to my ideas," instead of "a properly designed plant," would be arranged for a maximum lift of 10 ft. I enclose a tracing covering this point. The *average* lift is of course much less, varying from minus 10 to plus 10 ft. This is Mr. Bosqui's



The Butters Filter.

The Editor:

Sir—As Mr. Nutter says, in your issue of February 16, the data given in my former criticism were not taken from the plant at Millers, since at the time of my visit to that camp, the plant was not in operation.

I am glad to get the data supplied by Mr. Nutter, and knowing the possibilities of the filter, I feel sure that the results now being attained by Mr. Parsons will shortly be even better.

arrangement at the Combination mill at Goldfield, Nevada. The actual maximum lift varies from hour to hour, depending on the stage of the tide in the various tanks of pulp, solution, and water. It is therefore clear that any construction entailing a maximum lift of 25 ft. will necessitate large pumps (or more time) and more power. The tracing sent you is wrong in showing the discharge from the pump to the wash solution tank as going over the top of the tank. This should be connected to the tank below the low-water level. It will be easily

seen from this drawing that the greatest possible lift would occur in returning pulp or solution, with the storage-tanks full at the moment that the filter-box was empty. This tank is 10 ft. higher than the outlet of the filter-box, and I am unable to see any advantage to be gained by increasing this height. The same arrangement can be applied to a plant of whatsoever size.

As regards the cubic capacity of the filter-box, I must explain that this depends upon the spaciug of the leaves, and this spacing depends upon the nature of the slime treated. As an example, experiments are being made upon slime here in Guanajuato of which a cake 1½ in. thick forms with a 22 in. vaccum in 30 min. This slime necessitates a spacing of five or more inches (instead of four). The filter-box for this slime will be 5 ft. 10 in. from the top of the filter-leaves to the hopper, and the latter will be 6 ft. 3 in. deep. I repeat that for 250 leaves for slime ordinarily produced in milling, a Butters filter-box should not exceed 7,000 cubic feet.

As regards the time and size of pump necessary for transferring pulp and water, and taking Mr. Nutter's figure of 1,900 cu. ft. as the displacement of the loaded leaves, 5,100 cu. ft. of pulp would have to be transferred. A 10-in. pump (I have no data at hand on the capacity of a nine-inch pump) would actually require "according to the manufacturer" 7.5 min. and 15 h.p. to do this.

As regards filter repairs, it is hardly putting it strongly enough (in view of the fact that Butters filter-leaves have been in operation over two years without any signs of deterioration) to merely say that filter repairs are "less" for the Butters than for the Moore process. One of the great points of superiority of the Butters method is that the leaves hang perfectly still, and are subject to no strains, are not scraped (as are the "better type at Bodie") or even touched for months at a time.

As a point of interest, I may state that the filter now being constructed for the Pinguico mill of this place, is designed on "gravity" lines, as illustrated in your issue of recent date, and not "all pumping;" and in this case (where the filter is filled and emptied by gravity, and the pulp returned from a low sump-tank) their maximum lift will not exceed 30 feet.

I must not be suspected of being convinced of the merits of the Butters filter on account of being interested in its success—rather the contrary, having become interested after conviction as to its merits.

MARK R. LAMB.

Guanajuato, Mexico, March 6.

[Having been favored by Mr. Lamb with a copy of the foregoing contribution, Mr. E. H. Nutter writes to say that "the filters at Bodie have not been, and are not, scraped in order to clean off the cake. The discharge is accomplished entirely by blowing the cake off with compressed air, as stated by Mr. R. Gilman Brown in an earlier article."—Editor.]

Assay of Cyanide Solutions.

The Editor:

Sir—Will you kindly publish the following scheme for the assay of cyanide solutions; it is a modification of Crosse; it is quick and accurate, does away with tedious evaporation, and chance of loss, and the furnace.

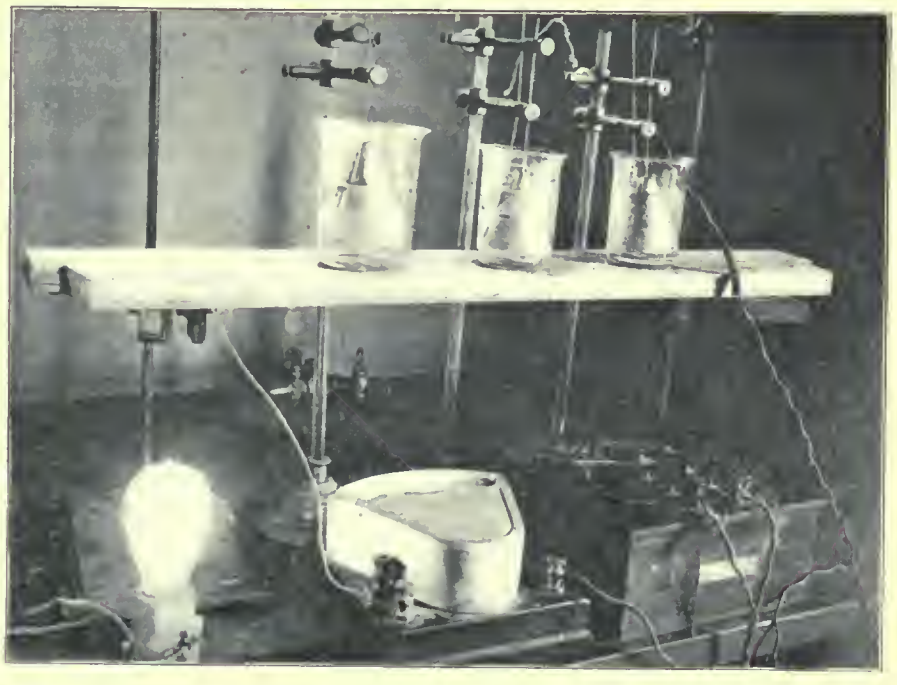
Measure 30 c.c. KCy (working solution), add silver nitrate solution used ordinarily in titrating, until precipitate ceases to form; the gold is all now precipitated as argenti-auric cyanide.

Allow precipitate to settle; decant clear solution, then with wash-bottle transfer precipitate into small funnel, using thin paper; wash several times to get precipitate well down into point of paper; draw out paper and cut off just above the precipitate; place this cone into a hole cut in charcoal, blow-pipe, flatten, part, anneal, and weigh.

H. W. GENDAR.

Ballarat, Cal., March 5.

[Many thanks. Such hints are useful.—Editor.]



Apparatus for the Electrolytic Assay of Copper Ore.

Electrolytic Copper Assay.

The accompanying photograph shows the electrical apparatus used by E. R. Pichrell, a senior student at the Washington State College, in experimenting upon the electrolytic assay of copper ore. The ores treated came from Phœnix and Rossland, B. C., from Butte, Montana, from Hadley in Alaska, and from two camps in Washington. They ran from 1 to 70% copper. It was found that by using a direct current of 120 volts and stepping it down with an 8-volt light and rheostat to a current of 0.5 amperes and 8 volts the electrolytic copper assay could be made in the short time of 2½ hours, instead of 12 to 14, as is usually the case in assay-offices using this method. In all the experiments exceedingly accurate results were obtained. The samples were run in triplicate and most of them checked to hundredths, the average variation being one-tenth of one per cent.

THE temperatures at which some of the metals fuse are as follows, all expressed in degrees Fahrenheit: Tin, 442; zinc, 773; lead, 617; silver, 1,832; copper, 2,200; gold, 2,518; iron, 2,800.

Some New Points in the Geology of Copper Ores.

Contributed to the MINING AND SCIENTIFIC PRESS
By JAMES F. KEMP.

*During the past year or two cobalt and silver have been the metals most prominently in the foreground in Ontario; but south of the national boundary and in other parts of the world, copper has occupied the centre of the stage. The growth of electrical applications and the increasing consumption of brass have made the market wellnigh insatiable. Copper mining has greatly increased, and with the growth of new districts and with widening experience, we have found it necessary to modify some of our old-time conceptions.

Twenty-five years ago when the classes in the mining schools were taught the mineralogy of the ores of copper, it was chalcopyrite that was esteemed the principal mineral. Of course the importance of the native metal on Keweenaw Point† was appreciated, but we used to define an ore as "the compound of a metal and a mineralizer such as sulphur or oxygen"—and the native form, even though abundant in one locality, was thus ruled out. Experience with the lenticular beds or veins, in the slates and schists along the Appalachian belt from Sherbrooke, Quebec, to Ducktown, Tennessee, and the historic orebodies of the Rio Tinto district in Spain, whose geological relations are similar, gave good ground for the esteem in which chalcopyrite was held. It was considered, moreover, to be the original mineral from which the others were generally believed to have been derived. Observers of those days were perfectly familiar with the oxidized zone, and with the zone of enrichment, at the level of the ground-water. At the latter horizon the Ducktown mines had taught all of us in America that rich black ores were precipitated, but the dark mineral was for many years believed to be the oxide, tenorite or melaconite, until W. H. Weed proved it to be chalcocite. Chalcocite was esteemed to be rather uncommon, and, when we students saw it at all, it was chiefly in the crystals from the old copper mine at Bristol, Connecticut, an enterprise that had astonished its shareholders rather by the lack of copper than by its abundance.

Today, on the contrary, in the United States and Mexico, chalcocite furnishes much the largest part of the copper produced, and for some years to come its relative importance bids fair to increase rather than diminish. Butte, Morenci, Bisbee, Globe, and Cananea derive most of their output from it, while Bingham and Ely will soon be concentrating the glance from the porphyries on an enormous scale.

So far is chalcopyrite from being the principal and original mineral at Butte that, on the one hand, it is rather uncommon and, on the other, it is one of the latest of the secondary minerals, since we find it in veinlets cutting covellite. The original mineral alike at Butte and in Arizona appears to be a lean copper-bearing iron pyrite, which is then, by secondary enrichment, oxidized in one place and deprived of its copper, only to gain the latter elsewhere in the form of chalcocite, which brings the lean original up to grade.

In later years and for a period lasting well up to the present, we laid great and just emphasis on the processes of secondary enrichment by the descending surface waters. We believed that the new chalcocite and other minerals were deposited at the level of the ground-water and for a limited distance below it. That is, we gradually grew to recognize the necessity of a greater diffusion of the descending copper solution throughout the quiet ground-water than we had at first thought either necessary or probable. But in the issue of the MINING AND SCIENTIFIC PRESS for February 23, 1907, page 236, we learned that a cross-cut in the Berlin claim at Butte had cut a great body of glance, at 1,800 ft. from the surface, and that in the Neversweat, at 2,400 ft., a similar occurrence had been noted. Even before this it was generally reported that a cross-cut from the shaft at 2,000 ft. in the Speculator claim had intercepted these rich ores in a still different lode.

Various suggestions tending to reorganize our old views either have been made or may be made in consequence of these discoveries. The hillside on which the copper mines are situated at Butte rises gradually to the north from the valley of Silver Bow creek, or more steeply to the west from the same creek at Meaderville. In the latter area shafts are said to have found the bedrock under 600 ft. of overlying loose material. Obviously, as the valley was excavated by erosion, and as the former representative of Silver Bow creek established the low point of the ground-water upon its bedrock itself, the subterranean water-level must have risen from this point, in the hill, roughly following the surface, but at a flatter slope. The present outcrops of the copper veins are from 500 to 700 ft. above the present valley, or from 1,100 to 1,300 ft. above the bedrock. To estimate the ancient level of the ground-water we must diminish 1,100 to 1,300 by such figures as will allow for its rise, roughly parallel with the surface. Whatever assumptions we make, moreover, regarding wall-rock and vein-matter removed by erosion, but operate to further raise the ground-water level. It certainly can scarcely have been lower than 800 to 1,000 ft. below the collars of the present shafts. The recently discovered bonanzas are from 1,000 to 1,500 ft. below this level, and, according to our old ideas of the diffusion of the descending copper-bearing solutions, they must have penetrated at least 1,000 to 1,500 ft. of standing water. This seems unlikely.

On the other hand, we may raise the question, could the ground-water have been so irregular in its distribution that no standing body of it intervened to stagnate the descending water? This seems unlikely. Again, is chalcocite necessarily a secondary mineral? May it not be of original deposition? Experience thus far leads us to think that the presumption of its secondary nature is well grounded.

Most reasonable of all would appear to be W. H. Weed's suggestion of secondary enrichment by uprising solutions of copper—set in action perhaps by the late rhyolite. From these no lean pyrite of primary deposition thus far observed would be too deep to escape, although solutions of oxidized copper salts such as bring about the enrichment by descending surface waters are not what we associate with waters uprising from the depths. Mr. Weed applies his conclusions especially to the enargite at Butte, but, as the glance is being found deeper and deeper, we may at least raise the question whether its lower deposits may not also have been introduced from the depths.

Ten years ago, or even less, great apprehension was felt about the persistence of the ore in depth. The newly appreciated doctrines of secondary enrichment from above had emphasized and increased the misgivings, and much experience corroborated them. Rio Tinto was most often cited, where, in the San Domingo vein or lens, 4 to 5% of copper had been obtained at the surface; 2% at 260 ft.; 1½ to 1¾% at 325, and 1¼% at 425 ft. In the Dionisio there was 4% at the surface; 2% at 650, and 2½% at 1,500 ft. In the last citation there was a ray of comfort, but the general result was decidedly discouraging. At Butte, too, the general yield of the ores has

*Read at the meeting of the Canadian Mining Institute, Toronto, March 8, 1907.
†The copper region of Lake Superior.

gone down. A few years ago it was 5 to 6%; now it is 3 to 4%. In Arizona 15 to 20% was not uncommon twenty years ago. The ores run 6 to 7% now and the glance in the porphyries 3% as it goes to the mill. Improved transportation and milling processes are responsible for bringing lower and lower ores within the range of profit, and, as we must realize, there is the tendency steadily to reduce the general average; but if, at Butte, 40% ore occurs in great stopes at 1,800 ft., and 60% ore at 2,400 ft., we may raise the question as to whether the old-time generalization is as sweeping as we formerly thought.

Reverting again to the time-honored conceptions of the lenticular orebodies or *kieslager* of the slate and schist of the Appalachian belt and of Rio Tinto, many of us will recall that these were esteemed our typical deposits. But in later years developments in the southwestern United States, in Mexico, and in Queensland, have proved the frequent occurrence and great importance of garnet zones produced by contact metamorphism in limestone along intrusive rocks. Bisbee and Morenci in Arizona; San Pedro, New Mexico; Aranzazu and San José, Mexico; Chillagoe, Queensland; and many more, have shown the importance and wide distribution of this type. Garnet, vesuvianite, wollastonite, and diopside are the associated minerals, and the orebodies are of irregular shape. They often need secondary enrichment to bring them up to grade. They are not lenses as are the ores at Thedford and Rio Tinto; nor veins as at Butte; nor beds as at Mansfeld; nor impregnations of shattered rock as at Nacosari; but are a new type when compared with our old conceptions.

One of our tendencies in earlier years was to connect orebodies, especially of copper, with basic eruptives. Keweenaw Point and Sudbury gave good support to these inferences. It was also natural to infer that, as iron and the other bases increased in rocks, therefore copper, lead, and other metals would do the same in less degree. But recent experience is just the opposite in the case of copper. Globe, in Arizona, with its diabase, and the Nikolai and other greenstones of the Northwest coast are almost the only basic ones that appear in the newer districts. On the contrary, we find quartz-bearing rocks of various kinds, and more especially a fairly acidic variety midway between syenite and diorite, called monzonite. Bingham, Ely, Bisbee, Morenci, Nacosari, and the granite at Butte all afford a similar experience. The great deposits of northern California are in rhyolite porphyries. We cannot but reflect that the acidic magmas are richest in dissolved vapors, that they probably in cooling yield relatively abundant magmatic waters; and that, being at the outset copper-bearing, the orebodies are perhaps due to these characteristics.

But the most striking feature of the last year or two is the tendency of mines first worked for other metals to yield copper in depth. From Butte we learn that the silver mines along the Rainbow lode, in which, in the upper workings, no copper was found, are now showing as much as 3% at 1,000 ft. The old Black Rock claim, once a silver mine and a participant in the famous Black Rock-Niagara apex suit, is being revived and deepened for copper; and others in the vicinity are actually yielding the red metal. The Cable gold mines farther west in Montana supply now 3% ore to the Washoe smelter. Bingham, once a lead-silver camp, has changed to copper. From Leadville the same report has been coming for some years, that much copper was found with the unchanged sulphides in depth. At Red Mountain, where, near the surface, lead-silver was formerly the yield of the ore, now, in the 1,100-ft. adit into the mountain, copper has been found. In North Carolina, some gold mines of former years have become copper mines today. Most striking of all, at the great Mt. Morgan gold mine at Queensland, the diamond-drill, at 725 ft., has shown great bodies of copper-bearing sulphides, which now go to the furnace, as the earlier gold ores went to the chlorination mill.

We have for years known that lead above often passed into zinc below. We may perhaps now add a still deeper copper zone, when, in the uprising waters that brought in the ore, copper was present with the other two. Gold above may also change to copper below, or be associated with it, and apparently not always because copper once general throughout the vein has passed downward with the atmospheric waters.

An interesting corroboration is thus afforded of views advanced by W. H. Weed in the paper already cited, of which one of the closing paragraphs is: "Ascending hot-spring waters, if metalliferous, may deposit different ores with an orderly vertical distribution. Existing veins now mined often show their arrangement of metallic sulphides." *

Sulphur in Utah.

Sulphurdale is a small mining camp about 20 miles north of Beaver, Utah. The deposits are locally known as the Cove Creek sulphur beds. Cove Creek sulphur has supplied the local market for about thirty years, the average annual output being estimated at 1,000 tons. An area of several acres has been exploited, but the lateral extent as well as the depth of the deposits is unknown.

Some of the sulphur occurs in cylindrical masses or cores 10 or 15 ft. in diameter, having a rude radial structure as if they had been formed about a central vent extending indefinitely downward into beds of tuff. But it occurs mainly as a dark-colored impregnation or cementing substance in the rhyolitic tuff. In certain places it appears as irregular veins of nearly pure, yellow sulphur ramifying through the beds. Occasionally a smaller cavity is found lined either with flowers of sulphur or with sulphur crystals.

This sulphur is probably the result of volcanic action, as shown by its presence in a volcanic region where recent eruptions have occurred. Gas is escaping in large volumes, in some areas by thousands of small jets from the porous beds of tuff. Wherever water is found standing in the excavations, the gas is noted boiling up through it at short intervals.

The ore varies in richness from a trace to practically pure sulphur. Samples taken at the extremities of the workings and analyzed in the laboratory of the Geological Survey were found to contain respectively 80 and 65% sulphur. Material running as low as 15% is considered paying ore. At the smelter the ore is placed in iron retorts and the sulphur is melted out by steam. Analysis of the product, as it comes from the retorts, shows that it contains 99.71% sulphur, 0.23% non-volatile residue, and 0.06% moisture.

In the gold belt of Western Australia all the characters of the deposits point to genesis under conditions of great depth and dynamic metamorphism; the deposits, although occurring mostly in amphibolites and slates, are later than the granites intrusive in the former rocks, and are probably in closest genetic relations to the granites. Analogous occurrences are those in Victoria and California, where the gold veins are usually contained in the schists and slates, although they assuredly were formed closely after the intrusion of great masses of granitic magma.—W. Lindgren in *Economic Geology*.

A Simple Classification of Igneous Rocks.

Prepared for the MINING AND SCIENTIFIC PRESS
By SCOTT TURNER.

The accompanying table is designed to help in the identification of the common eruptive rocks. It is arranged in a condensed form and is based on Rosenbusch's classification and a subsequent more elaborate tabulation by F. E. Wright. The general heading 'Lime-Alkali Series' is given to distinguish this group from the rare group in which the feldspars contain no lime, and which is known as the 'Alkali Series.' The rocks of the alkali series are generally characterized by a duller color, and the only rock of special importance that it contains is phonolite, which does contain some alkali-feldspar, along with nephelite or leucite, and is porphyritic in texture.

Identification is accomplished with this table, by means of two co-ordinates, arranged in horizontal and vertical columns. These co-ordinates are texture and mineralogical composition. The three abcissæ thus are the three textures, namely, granitic, holocrystalline-porphyritic, and porphyritic. The first needs no explanation, being a term suggested by granite, and used to describe those igneous rocks that are composed entirely of recognizable minerals, approximately the same in size, and in which there is no groundmass. Hypidiomorphic-grained is a term that has been used to describe the same texture. The rocks included under the second head of holocrystalline-porphyritic texture, are those that are entirely crystalline, but with crystals of different size, and no groundmass, giving a porphyritic appearance. They are deep-seated magmas that have solidified in dikes, with the same chemical composition as the deep-seated forms. The third heading—porphyritic texture—includes those rocks that have comparatively large crystals or phenocrysts, embedded in a finer-grained groundmass, which is often finely crystalline, but which may be even glassy in some cases. The name of the holocrystalline-porphyritic rock is formed by adding 'porphyry' to the name of the corresponding deep-seated variety, if the feldspar is orthoclase, and 'porphyrite' if the feldspar is plagioclase.

The characteristics that are arranged as vertical co-ordinates, refer to the mineralogical composition of the rock, which, having been once ascertained, and considered in connection with the texture, determines at once the position of the rock in the table. For instance, if it has been ascertained by inspection of the hand-specimen, or the thin section under the microscope, that the texture is porphyritic, and the principal mineral constituent a feldspar with no triclinic striations showing, and probably an orthoclase variety, and that there is no quartz present, glancing down the 'porphyritic' column to the point where the 'alkali feldspar, no quartz' horizontal division meets it, it is seen that the rock is trachyte.

The chemical composition of the rocks in the granitic and porphyritic columns is given. These are average values, obtained from the analyses of several typical individuals in each class. The silica and alumina content is given for each; also the iron oxides, including FeO and Fe_2O_3; the alkaline earths, MgO and CaO; and the alkalis, Na_2O and K_2O. The water, and the titanic and phosphoric acid content are not given, as they are relatively unimportant, and small in amount. The amount of water varies from 0.6%, to a maximum of 3% in the peridotites, and 5% in the picrites, but seldom exceeds 1% in the others. The phosphoric acid ranges from 0.1 to 0.3%, and the titanic acid, TiO_2, runs from 0.3 to 0.9% in the rocks included in the table. An increasing basicity will be noted in proceeding from the top to the bottom of the table; the granite is the most acid of the deep-seated rocks, with a silica content of about 68%, and the pyroxenites are the least acid, with only 43% SiO_2, all others being intermediate between these two extremes. In the porphyritic column, the rhyolite is the most acid of all, with 75% SiO_2, while the basalts contain only 50% of silica.

Only the essential components are given in the classification. The tabulation might be made more complete by including, besides the essential components, the appellative as well, which might be still further subdivided into auxiliary and accessory constituents. The table being condensed, these are omitted in column-tabulation, but show in the variety names under the general family head. Thus, it will be readily understood that a hypersthene-granite is a granite containing the mineral hypersthene as an auxiliary component.

Under each family head are grouped the more definite variety-names, which are determined by the appellative constituents, and other characteristics. Thus:

GRANITE is the general name for the family, and is typically a rock containing quartz, feldspar (orthoclase and oligoclase), and mica (biotite and muscovite).

GRANITITE is a special name for a biotite-granite.

AMPHIBOLE-GRANITE, PYROXENE-GRANITE, and HYPERSTHENE-GRANITE, explain themselves.

RHYOLITE is also called QUARTZ-PORPHYRY, and LIPARITE. Under this name are grouped a list of more definite terms that are used as prefixes to the family name. Thus:

MICROGRANITIC-RHYOLITE is one in which the groundmass consists of quartz and feldspar crystals on a small scale, but shows under the microscope as granitoid in texture. GRANOPHYRIC-RHYOLITES are those in which the quartz and feldspar crystals have formed simultaneously and inter-penetrate each other. FELSITIC-RHYOLITES are finely crystalline, and have but few, or no phenocrysts. VITROPHYRIC-RHYOLITES have glassy groundmasses. OBSIDIAN is volcanic glass. PITCHSTONES are hydrated rhyolites with a resinous lustre. PEARLITE is hydrous, with a concentric structure. PUMICE is a cellular variety.

GABBRO, as a variety-name, indicates the presence of diallage.

NORITE is a gabbro with plagioclase and orthorhombic pyroxene, generally hypersthene.

ANORTHOSITE is principally labradorite.

BASALT, as a family-name, includes all dark, basic volcanic rocks.

BASALTS and MELAPHYRS, as used in the table, are dark colored, dull rocks, often either aphanitic or fine-grained, with basic lime-alkali feldspars and augite. Rosenbusch uses melaphyr to mean a pre-Tertiary olivine-basalt.

DIABASES are a special form of basalt. Strictly speaking, they are not porphyritic in texture, the diabase texture being peculiar to this form. In the diabase texture the feldspars are lath-shaped, and well formed, the augite crystals filling the interstices. They are often green in color.

In the table, the class of acid and basic differentiation products is omitted, although it might be arranged in a fourth column under a general head of dike rocks. The APLITES AND PEGMATITES are the chief ones. APLITES are young dike rocks, occurring in nearly all granitic areas, and are simply a muscovite-granite dike rock, finely crystalline, containing no colored constituents, and with small cavities into which well-formed crystals project. PEGMATITES are coarse-grained quartz-orthoclase feldspar dike rocks, containing large feldspar individuals, with several quartz-masses which show prominently in each feldspar cleavage face, and intercalated between the feldspar individuals.

Condensed Table.

The Smelting of Cobalt Ores.

By Hiram W. Hixon.

*Experience in custom smelting permits me to suggest a system of treating these ores, as is herewith submitted:

1. The ores should be sorted, the metallic silver being separated for direct smelting by cupellation with lead, or melted in crucibles and poured into bars to be sold to refiners.

2. The ore should be ground in a dust-proof ball-mill to such a fineness that it can be accurately sampled.

3. The ground ore should be roasted in a suitable furnace to expel the arsenic and sulphur.

4. The gases from this roaster should pass through a long sheet-iron dust-chamber to cool them and then be passed through a bag-house where all the dust and volatilized arsenic will be recovered.

5. The roasted ore should then be briquetted with a strong bond of red clay and lime-water and dried or frozen, after which it should be smelted in a blast-furnace with about an equal weight of galena or lead concentrate containing about 50 to 60% lead. The necessary iron and lime would have to be added to the charge to produce a slag of the proper composition.

The sulphur for matte-formation would be supplied by the galena, while the arsenic remaining in the ore will form some speiss. The base bullion resulting from this smelting would be sold to lead refiners, or refined to separate the silver.

The matte and speiss will contain all the nickel and cobalt that can be recovered from the first smelting and also some lead and silver. This matte and speiss should be accumulated until sufficient for a special run and then ground in the ball-mill, roasted and smelted separately with more lead to free it from silver. The resulting bullion is sold or refined.

The second matte should be run into a converter, to free it from iron. In the process of converting, the lead, and most of the cobalt, will oxidize at the same time as the iron and go into the converter slag, except that portion of the lead that is volatilized with the remaining arsenic. This will go with the flue-gases and should—for safety—be passed through the bag-house, as they are both poisonous.

The converter slag will, therefore, contain the greater portion of the cobalt as oxide, and, in order to recover, it should be re-smelted in a separate blast-furnace along with a portion of the briquetted flue-dust from the roasting of the ore. The flue-dust highest in arsenic should be used, as the recovery of the cobalt depends upon the formation of a cobalt speiss or arsenide of cobalt. This would be separated from the slag in the same manner as the matte and its further treatment for cobalt would be by chemical methods, after roasting to expel the arsenic, which should be recovered in the bag-house in the manner first described.

The flue-dust containing arsenic would have to be roasted separately to sublime the arsenic, which should be recovered in a separate flue and bag-house provided for that purpose. The arsenic would be marketed as white arsenic, and great precaution would be necessary to provide against poisoning.

By the scheme outlined, the silver would be produced either as silver or in base lead bullion; the nickel would go into high-grade nickel matte containing some cobalt suitable for further refining by the Orford, Mond, or other processes; the cobalt would be produced as cobalt speiss, and the arsenic as white arsenic.

The smelters who buy these ores have not seen fit to give out any information, but the fact that they allow nothing for nickel, cobalt, or arsenic, is significant. To make even an attempt at a partial recovery of each of the metals, is a tedious process and most complicated, from a metallurgical standpoint.

*Abstracted from the *Journal* of the Canadian Mining Institute.

Thawing Dynamite.

Dynamite is one of the things that can not be made fool-proof. In consequence, accidents and injuries from handling it are frequent, the most common cause being ignorance of the best method for thawing frozen dynamite. Every manufacturer of explosives issues periodically a pamphlet describing how this may best be done, the general direction being as follows: Dynamite freezes at 42 to 50° F., and will freeze hard at times when water or moist earth does not freeze at all. When dynamite is completely frozen the cartridge is hard. In this condition it may be impossible to explode it, even with a strong cap, and it surely will not develop full strength. It must be carefully and thoroughly thawed to make sure that it will explode and do good work. The proper thawing of dynamite is a simple operation, and there is no reason why it can not be done safely.

There are a few peculiarities of nitro-glycerine and dynamite that are constantly ignored by many blasters. A dynamite cartridge can be lit with a match and burned without explosion—almost always. It must not be laid against a hot steam-pipe or smoke-stack, or be buried in hot sand, or stood near a fire. Use a heat that can be controlled, and that can never rise above 100°, even when neglected. Dynamite begins to undergo a change at 158° F., and, from that temperature up, becomes more sensitive to shock, until at a temperature of about 356° it will explode simply from the heat. Dynamite is not water-proof, and should not contain over 1% moisture. All over this amount will decrease the explosive power. Dynamite soaked in water for 15 minutes will take up 10% water, which will reduce its explosive force by half, and may make it non-explosive.

The best thawer for dynamite is one in which the cartridges are inserted in tubes that are completely surrounded by hot water. The sticks may be carried to the work in this thawer. Never place the thawer over a fire, or try to heat the water while there is dynamite in it. For thawing on a large scale a building heated with a steam or water coil is good, provided primers, men, and tools are kept out.

Reaction for Nickel.—The test depends on the formation of nickel-dicyanodiamidine $Ni(C_2H_5ON_4)_22H_2O$, which is a very slightly soluble, yellow precipitate of stellate-grouped needles. It is less soluble in ammonia than in water, and is not decomposed by boiling with potassium hydroxide solution. Potassium cyanide dissolves it readily. To apply the test, a 5% solution of dicyandiamide is boiled for a minute with a few drops of hydrochloric acid; the nickel solution is added, and then an excess of potassium hydroxide solution. In very dilute solutions the precipitate only comes down after long standing. The presence of a large excess of cobalt does not interfere with the reaction.

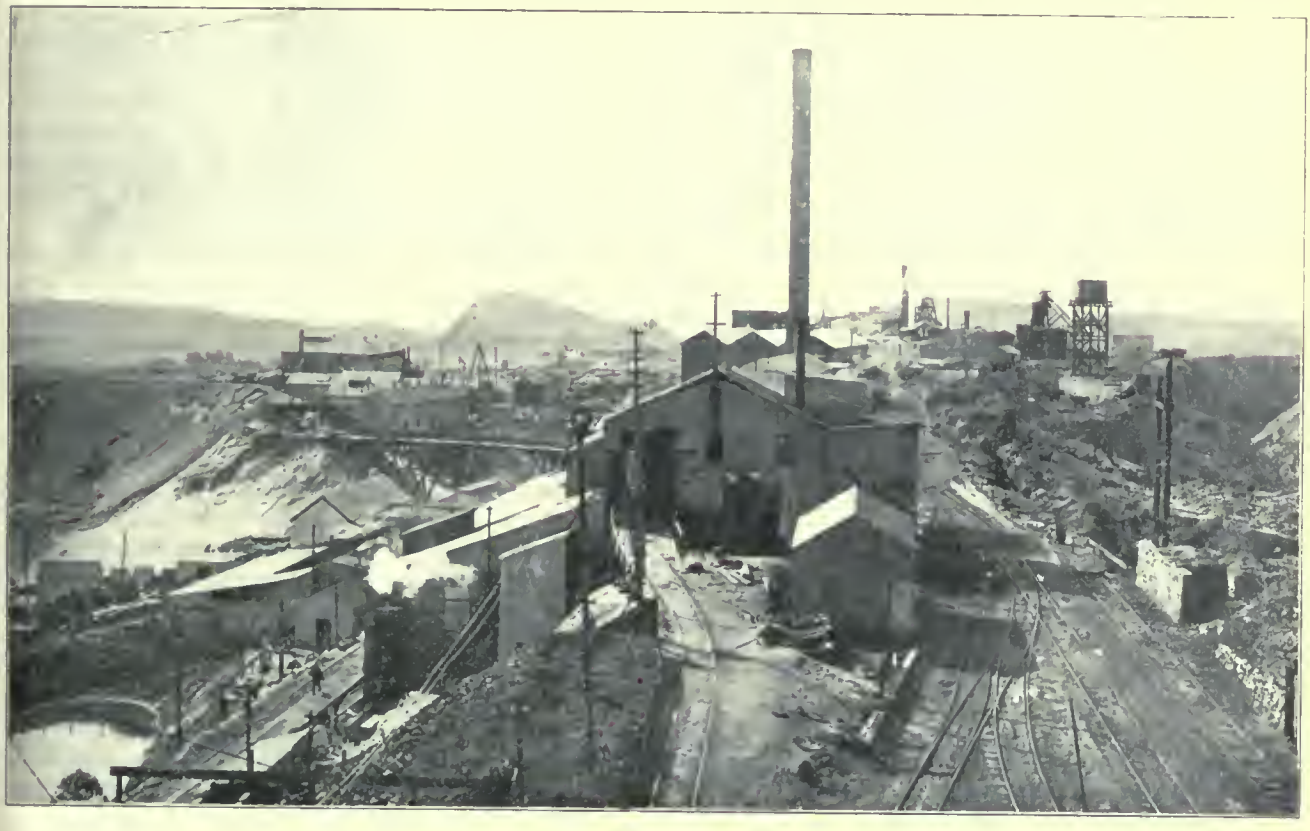
Nuggets.—The largest gold nugget ever found was the Welcome Stranger at Moliagul, in Victoria, in 1869. It weighed 2,520 oz. and was found at a depth of three inches. The Welcome nugget, found at Ballarat, in 1853, weighed 2,195 oz. and was discovered 180 ft. below the surface. Recently at Tarnagulla, also in Victoria, four nuggets, weighing 963, 675, 502, and 372 oz. respectively, have been secured in gravel at a depth of only 20 inches.

Ore Treatment at the Broken Hill Proprietary Mine.

By G. D. DELPRAT.

*The treatment of the Broken Hill ores has undergone many changes during the last ten years, and it may be of interest to some of our members to know what are the main lines on which the Proprietary mine works at present. It must be understood that the want of uniformity in the treatment among the various mines at the Barrier does not prove that some of the mines are working on wrong lines, for the ore is not exactly the same along the whole line of lode; this necessitates a variation in treatment, although generally only in detail.

At the Proprietary mine the ore is all mined by contract; the miners are paid so much per ton for clean ore.



The Broken Hill Proprietary Mine, New South Wales.

The ore in the mine in most stopes is mixed with gangue, and the inclination of the miners is, of course, to mix gangue with the ore, so as to be paid for as large a tonnage as possible. This is quite natural. Clean ore is easily distinguishable from clean gangue, but most lumps are a mixture of clean ore and gangue in varying proportions. The miner will naturally throw into his heap pieces which he considers still good enough, while the management may consider these pieces just a trifle too poor; consequently a check must be kept on this.

This necessitates the first operation to which the ore is submitted. The trucks (tare 5¼ cwt., average load 21 cwt.), as they are loaded underground, have a ticket attached showing to which contract they belong; on arrival at the top of the shaft they are passed over a weigh-bridge; the weight is entered in a book against the corresponding contract by the company's weigher, checked by a check-weigher appointed and paid by the men; this arrangement avoids all disputes. As the trucks leave the weigh-bridge, one is selected haphazard, tipped on a short inclined plate, where the ore lies in full view. A special man, called an 'ore inspector,' sorts this truck-load; he separates the waste from the ore; the ore is then allowed to fall through a chute into the same truck, which is raised by a hydraulic lift to the original level, and, after being re-weighed, rejoins the other trucks on their ordinary course to the mill; the result of the second weighing is that which is booked to the party. As soon as this truck is done with, another is taken, and so on. Generally, one out of every 40 trucks is taken and thus examined. If it is found that any party of men continually load waste into the trucks, such party is called to account; but this is seldom necessary.

On leaving the weigh-bridge, the trucks are hitched to an endless traveling steel rope, §-in. diam.; the distance of the trucks from one another on this rope is about 40 ft. The rope takes them to the tipping cradles, but before reaching these cradles they are automatically disengaged from the rope.

As there is a fall from the brace to the tipping cradles of about 9 ft. in a distance of 360 ft., there is very little motive power required to keep the rope in motion; in fact, when the work is fairly regular, so that an equal number of fulls are on the down-grade as there are empties on the up-grade, no power is required at all; power is practically only required on account of want of absolute uniformity in the work. The largest number of trucks disposed of in this manner for one shift of eight hours is 1,636, but the average per shift is 1,000.

The tipping cradles are placed above the ore-bins. The ore falls over grizzlies of tapered manganese steel. The life of these steel bars is about 12 months. The ore-bins hold about 800 tons and command five Gates crushers, No. 5, having openings of 10 by 30 in. in the spider. The crushers break the ore to 2-in. pieces. The cast-iron cones of these Gates breakers are covered with a removable mantle of toughened steel, and the outside shell of mortar is lined with manganese steel. It is found that, if the liners and mantles were both of manganese steel, the surfaces would wear too smooth, and the ore would not be gripped properly; one requires to be soft for grip-

*Abstract from an address by the president of the Australasian Institute of Mining Engineers at the Adelaide meeting. Mr. Delprat is general manager for the Broken Hill Proprietary Company.

ping, and the other hard for crushing. The life of the mantles is about 1,350 hours, and that of the manganese steel liners 2,700 hours. Many other combinations were tried, such as cast-iron with steel, and different kinds of steel, but the above gave the most economical results.

The crushed ore and the smalls then pass together into bins, which in their turn discharge into one-ton trucks. These are raised, two at a time, by means of a hydraulic lift to the original level on the top bins. The hydraulic elevator has two crushers on one side and three on the other, and the whole of this crushing plant stands between the two concentrating mills. When the trucks with crushed ore and smalls reach the top level they are alternately sent to the right and to the left — that is, to the one mill or the other — each mill having a capacity of about 6,000 tons of ore per six working days.

The new mill, which is the most up-to-date, will now be described: The broken ore is tipped from the trucks into bins, which command a set of three fast-running rolls 36 in. diam., 15 in. wide, ⅜ to ½ in. apart, with steel shells, and making 37 rev. per min. It is found that the shells which answer the purpose best are those of toughened steel; the thickness of these shells is 4⅛ in., and the life, taken over a good many shells, is approximately 3,000 hours. The shells are not turned up, but their surface kept smooth by shifting them sideways occasionally, so that the relative position of the shells opposite one another is not always the same.

The sampling of the ore going to the mill is done on the passage from the bins to the crushing rolls; a man goes around every hour and takes a scoop sample from the chutes that lead into the crushers; a sample is made up for every eight-hour shift; the total weight taken during the eight hours is 700 lb. approximately. This sample goes to the sample mill, which is arranged on the usual pattern, that is, the ore is crushed fine and mechanically divided and subdivided until a sample is obtained not too large for the assay office. A doubt arose whether or not the sample thus taken must be considered a fair sample. In order to test this, another man was put on to take an independent duplicate sample. As mentioned, the usual sample was taken every hour; the new man also took a sample every hour, but half an hour after the first man. The second sample was treated separately in the same way as the first sample. The first sample might represent samples taken at the hours of 8, 9, 10, 11, and so on; the second sample would therefore be taken at 8:30, 9:30, 10:30, etc. This was done for a period of six weeks; at the end of the six weeks it was found that the first sample assayed 16.46% Pb, and the second 16.57%, showing that the method of taking the samples was fairly reliable.

The ore (1½ to 2 in. in size) is fed automatically into the rolls by means of a roll feeder, assisted by a jet of water. On leaving the rolls, it passes over a rocking screen with 3/32-in. holes. The through ore goes to the concentrating plant, and the oversize falls on a traveling Balata belt, which discharges into the boot of an elevator, which elevator returns it to the original top level, and discharges into a second set of bins commanding a second set of three rolls, similar to the first set, but grinding finer and revolving at greater speed, making 45 rev. per min., and ⅛ to 3/16 in. apart. Here again the ore is fed automatically and follows the same process; that is, the through ore goes to the concentrating departments, and the oversize falls on a traveling belt similar to the previous one, and is again raised to the original level and discharged into a third bin. The third bin commands another set of rolls in the same way, which rotate at 78 rev. per min., and 1/16 in. apart; the oversize is raised in the same way into a bin, and from here into the last crusher, which is a No. 5 Krupp ball-mill, specially constructed for wet grinding; in this last mill the grinding reaches finality, as no ore can escape the ball-mill before it is crushed to a sufficient fineness to pass the screens.

From the description it will be clear that material that has once passed a set of rolls never comes back to the same rolls, but goes on to another set adjusted differently. This is one of the differences between the old mill and the new one. In the old mill the usual method is followed of returning the oversize of screens to the same set of rolls. The advantages of the new methods are, in the first place, that a much smaller proportion of slime is made, and in the second place that the gradual reduction effects at the same time a gradual concentration. That is to say, that the material fed into the first set of rolls is the richest. After crushing and screening, the oversize which goes to the second set of rolls is poorer, as the portion not crushed fine enough to pass the screen is the hardest, and therefore contains most of the gangue. The same selection takes place in the second set of rolls, and so on. The assay value of the feed into the first set of rolls is about 15% Pb, while the feed into the last set of rolls or ball-mill is only about 10%. It is found that this automatic selection gives an advantage in the working of the jigs and in the recovery.

The principle of never returning any ore to a machine through which it has once passed, but passing it on to another machine differently set, has been carried out as far as possible all through the mill. It seems right to conclude that a machine which allows material to go through without effecting its purpose should not be called upon once more to do it; the operation should be done in one differently set.

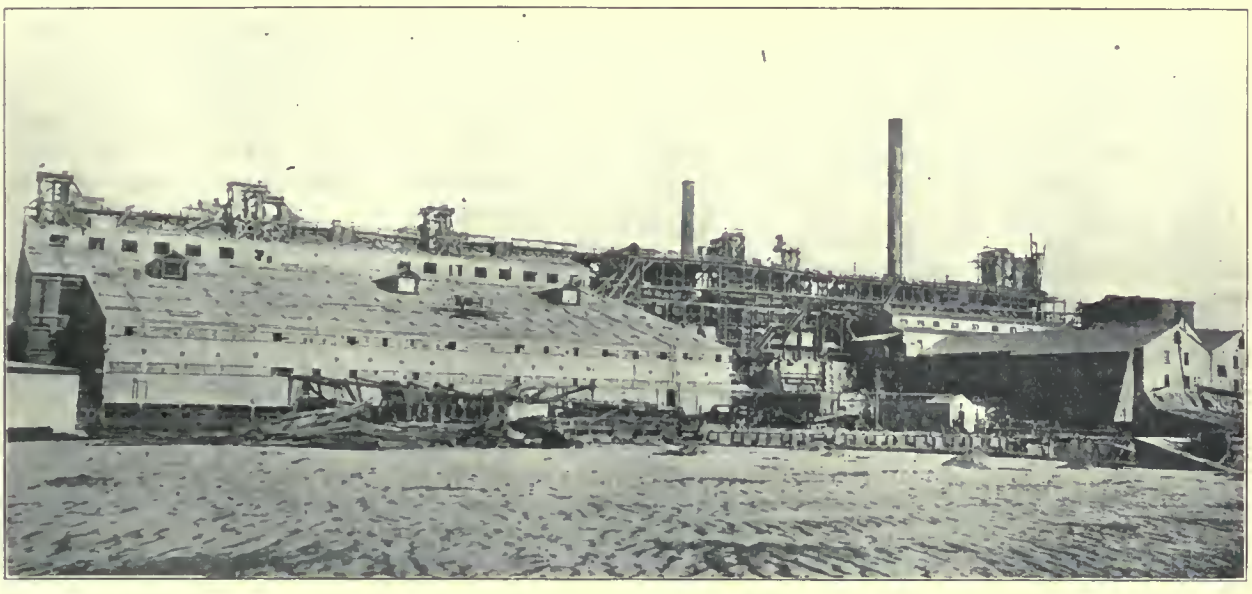
Instead of shaking screens, trommels were used at first, but it was found on experimenting with shaking screens that these did much more effective work than the trommels. The trommels only passed through 58% of the material that was fine enough to go through, while the shaking screen passed through 70%. Other advantages of the shaking screen over a trommel are:

1. Less initial cost.
2. Less water required for screening.
3. Repairs can be made so much more quickly, as it only takes about ten minutes to replace a screen plate, while in a trommel it takes hours.
4. The screen-plate lasts longer in the shaker than in the trommel; the screening area of a shaker is 21 sq. ft., and lasts six weeks, while a trommel to do the same work has an area of 54 sq. ft., and only lasts four weeks.
5. The shaking screen takes up much less room than a trommel, and is much more accessible for cleaning while in motion.

The ore is now all fine enough for the coarse jigs—that is to say, it will all pass through a 3/32-in. hole. On its way to the jigs (May plunger jigs with five compartments), the crushed material passes through a slime separator—an inverted cone with an inflow of water at the bottom, and an overflow which carries the water charged with all the slime. The coarse part of the material goes to the jigs, and the overflow slime to the slime department. In the first two compartments of the jigs, a concentrate of about 60% lead is obtained; in the third and fourth compartments a product assaying about 10% lead, 19% zinc, and 10 oz. silver; and in the last compartment tailing assaying from 3 to 4% lead. The discharge from these jigs is through a spigot at the bottom, and is continuous. The concentrate runs through launders into bins above the railway line, where it is drained of water, and when dry enough runs into railway trucks. The tailing is also run into bins, from which it is trucked to the tailing heap. The middle product is discharged into a

No. 4 ball-mill with slotted screens, 1/32-in. slots; the resulting pulp is raised by means of a bucket elevator into the fine jigs of four comparments, but on its way to these jigs it passes through a slime separator similar to the previous one, so as to remove the slime, which again goes to the slime department. The fine jigs make a concentrate assaying 40% lead, 13% zinc, and 22 oz. silver; a middle product assaying about 9% lead, 18% zinc, and 8 oz. silver. The concentrate and tailing are disposed of in the same way as with the coarse jigs, and the middle product passes into another ball-mill with screens with slotted holes 1/15 in. wide, and the resulting pulp is raised up to the slime separator belonging to the fine jigs. No handling of material takes place; every product finds its way automatically to its destination right through the process.

The slime coming from the various slime separators passes into V-shaped boxes, where it is classified into coarse and fine. The coarse goes to Wilfley tables, and the middling from these over a second set of Wilfley tables at a lower level, the concentrate finding its way to the concentrate bins, and the tailing to another set of bins, from which it is removed to the zinc-treatment plant.



The Broken Hill Proprietary Co.'s Mill.

The finer tailing classified into four sizes goes to the Luhrig vanners, upper and lower set, the same as the Wilfley, and the concentrate and tailing are disposed of in the same way.

During the crushing and subsequent grinding a fine slime is formed, which settles with great difficulty in the circulating water, and runs past all the concentrating appliances. This slime contains about 18% lead and 18 oz. silver, and forms a substantial portion of the total ore treated. At one time this slime was allowed to run away mixed with the tailing as untreatable, but now the circu-

Block 10 Mine, Broken Hill.

lating water is settled in a number of large tanks and the resulting slime (about 1,500 tons weekly, or about 12% of the total ore treated), is collected and further treated by means of the sintering process.

The recovery of lead in:

	Per Cent.
Coarse jigs is	7.50
Fine jigs	13.50
Willfley tables	3.15
Luhrig vanners	3.15

The quantity put through:

	Tons.
Coarse jigs, double, per hour, about	5¾
Fine jigs " "	2¾
Willfley tables "	¾
Luhrig vanners, single belt	⅙

From the former operations four products are obtained:

	Pb. %	Zn. %	Ag. oz.
Lead concentrate, averaging	55	10	26
Coarse tailing "	4	12	5
Fine tailing "	5	17	8
Slime "	18	17	17

The total quantity of ore put through the two mills is about 12,000 tons per week.

It will be noticed that sizing the broken ore previous to jigging is not done. At one time it was thought that sizing the ore—as is the practice in most concentrating mills—might be an advantage, but exhaustive trials made in this direction proved that with the Broken Hill ore there was no advantage in doing this. This may be due to the fact that the mixture of ore and gangue is so intimate that before any concentrate can be obtained crushing through a 3/32-in. mesh is necessary, and to size material smaller than this would be a cumbersome operation when dealing with such large quantities. However this may be, sizing did not give any higher recovery, nor was it more economical, and the idea was abandoned. This only refers to Broken Hill ores; other ores which are coarser should, no doubt, be sized previous to jigging.

AN interesting topic of discussion in the engineering world is the revival of the proposal to drive a railway tunnel under the English channel from England to France. The idea is an old one, but for several reasons has never been seriously considered. Now, however, the electric locomotive offers a solution of the problem and makes it practicable to draw trains through a tunnel over 20 miles long, placed under the sea where ventilating shafts cannot be constructed. The plan is one of some magnitude, involving as it does a 20-mile tunnel, with approaches 30 miles long at each end. But there are other engineering undertakings now being carried on which, while different in character, involve a greater amount of work, and the estimated cost of which is much more than that of the Channel tunnel, which, it is expected, would cost only about $30,000,000.

OF MINERALS associated with the native gold, in the mines of Kalgoorlie, Western Australia, tellurides prevail, and among these calaverite and coloradoite (telluride of mercury) are the most common. Pyrite is abundant, but almost always finely divided in contrast to the often massive tellurides. Further accessory minerals are chalcopyrite, blende, galena, pyrargyrite, enargite, lollingite, fluorite, magnetite, rutile, calcite, dolomite, siderite, ankerite, sericite, chlorite, and roscoelite. To these tourmaline and albite should be added.

THE presence of tourmaline, albite, and smaller amounts of magnetite and specularite indicates, I believe, that the veins were formed at great depth below the surface and at comparatively high pressure and temperature. The metasomatic processes active in the veins of Kalgoorlie are almost identical with those characterizing similar deposits elsewhere, for instance, in the California gold belt and at Cripple Creek.—Waldemar Lindgren.

Politics and the Transvaal Mining Industry.

Written for the MINING AND SCIENTIFIC PRESS
By EDGAR P. RATHBONE.

Since the first discovery, about twenty years ago, the Witwatersrand goldfield, occupying the comparatively small area of approximately a hundred square miles, has been the centre of more political unrest than any other district in the history of gold mining.

As I have had some personal connection with much of this political trouble, and as at the present time I take keen interest in the future political and industrial development of the Transvaal, I trust that my views on the present political situation will be welcome to some of your readers.

To commence with, I cannot too strongly insist, after a fairly intimate knowledge of the genuine Boer, as represented by such men as Louis Botha, De la Rey, and others, and also of the old 'colonials,' attracted to the Transvaal by the discovery of gold, that whatever else may happen politically in the future history of the country, *Krugerism is dead;* nor will it ever again be possible for an ambitious Hollander like the astute Dr. Leyds, to form out of the Transvaal what at one time was not only possible, but probable, namely, a strong and independent Dutch republic, as a nation of Transvaalers, greater and far more prosperous than Holland itself had ever been.

It was, I am firmly convinced, with the object of realizing this ambitious dream, that both Boer and Hollander fought during the late Boer War. Had Paul Kruger been possessed of a greater intelligence and been of a less stubborn character and at the same time listened more to the progressive Boers, who now form what is known as the Het Volk party of the Transvaal, the Jameson Raid would never have taken place. Even after the Jameson Raid, had Paul Kruger chosen to forgive and forget, and wisely granted a certainly reasonable measure of franchise to those who became naturalized citizens and took the oath of allegiance, his power in the Volksraad would not have been dangerously weakened and he probably would have been living today as the uncrowned King and powerful President of an immense and prosperous Dutch republic in South Africa. Under such conditions, disloyal as it may sound, I believe that the gold-mining industry would today have been in a far more prosperous condition than it now is under British rule.

The reason for this is not far to seek. The prosperity of the Transvaal depends largely on an intimate knowledge of the native and a proper policy in his treatment, and this, in my opinion, is a matter much better understood by the Boer and colonial Dutch and English of long residence, than by a British Government.

Since my return to England from the Transvaal, where I have resided during many of the best years of my life, I am constantly meeting those who seem still to fear that owing to the interference by the present Home Government in economic questions affecting the prosperity of the Transvaal, it may still be possible to so irritate both the Boer and old Colonial, that another rupture will take place. Before, however, this could possibly eventuate, all political parties in England would think and act alike! As to the country even going back to a state of Krugerism, with the most powerful of Het Volk, or Dutch representation, I do not believe it is possible, as there is no one to lead and dominate the old conservative and unintelligent Boer, as Paul Kruger undoubtedly did.

The great power at the present time of the Het Volk, or Dutch party, is that it mainly consists of a people content, like the native element, to reside permanently and make a 'home' in the country that they

can feel to be, and call, "*Our* land," whatever its Government might be. As for the others, they are still practically *uitlanders*, or foreigners, whom Paul Kruger at one time accurately described as those who came to fill their pockets out of the gold mines, and then went elsewhere to spend their money.

A Boer is content to live that simple life which to others accustomed to a higher civilization simply spells misery. The actual cost of living on the Witwatersrand must of necessity always remain comparatively high, since practically everything that makes life worth living, besides the bare necessities, must for a long time to come, be imported from countries 6,000 to 10,000 miles away.

At present, and in any case until there is a much larger population in the Transvaal and South Africa generally, the mining industries, principally confined to gold, coal, and diamonds, will be the only ones that will materially support this enormous continent of South Africa. The prosperity of these industries, as well as of agriculture, absolutely depends upon a plentiful supply of low-waged unskilled labor. Neither the Boer, nor certainly any civilized white European, will ever be willing to enter into competition for the wage that a Kaffir is more than content to receive.

In order that the Boer and the colonial immigrant, or old resident in the country, can even begin to think of cultivating the land and producing food-stuffs within the country, a plentiful supply of unskilled labor that can *compete* with the native on even terms is essential, and how can this be obtained if all of it, and far more than is now obtainable from all sources, is always to be absorbed by the gold mining industry?

Doubtless reduced ocean freightage and railway transport and a big reduction in duties on the necessaries of life, will account for some reduction in the cost of living, but if this only means that it has finally to be put onto the gold mining industry in the form of an increased gold tax, it is merely robbing Peter to pay Paul. It is too late now to talk of shutting down mines and restricting a large portion of the world's gold output and thus throwing South Africa back into barbarism. Towns have arisen and a large population has been attracted by this gold mining industry and the hands of the clock cannot be put back. The world requires an ever increasing amount of gold and at least one-third of it will continue to be supplied by the Witwatersand gold mines for the next 50 years or more.

Under these circumstances it is therefore certain that the future Transvaal legislature, whether composed principally of Boer or Briton, is bound to find some way that will permit of the steady increase in the prosperity of the Transvaal and its gold mining industry. For my own part, I still believe that, in the continued importation for mining purposes only, of strictly indentured Chinese coolies from northern China, lies the only practical solusion of the unskilled labor problem and that finally the mines of the Rand will be entirely worked by them. This would liberate the Kaffirs now working in the mines, and permit of their being employed by the Boers on the agricultural land, and thus gradually make it possible to produce at least some food-stuffs, and so reduce the cost of living as to enable more whites to be employed upon ordinary unskilled mining work. In this manner there would finally grow up a number of immigrants and others that could be included among the permanent population, who look upon the Transvaal as their home.

The forthcoming Transvaal elections will, I believe, result in the formation of a strong Nationalist party with Sir Richard Solomon as its first Premier, and the Boer element included in it will be strong enough to keep Sir Richard, who is credited with being a negrophilet, in check while insisting on a firm and just native policy—such a policy as would, in fact, induce every available and able-bodied Kaffir in the land to work hard and continuously, as all white unskilled labor has to do in other countries where there is competition.

As to the Chinese, I believe, that on the mines after some fencing has taken place between British and Boer politicians, they will continue to be employed under conditions that, despite some juggling with the words 'servile labor,' will not offend even the most sensitive minds.

Under these conditions I look for a period of greatly increased prosperity for the whole of South Africa, during which 'deep level' and 'deep deep-level' companies will be able to start work and produce gold, like the outcrop companies have already done or are doing. In this prosperity other countries will also benefit by the importation of increased amounts of machinery and stores, especially Great Britain, so that even a Liberal and a Radical Government could then afford to look with complacency on the retention of Chinese labor.

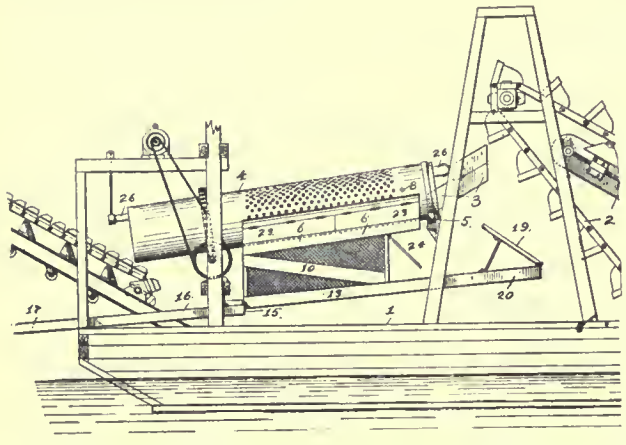
[Mr. Rathbone was formerly Government Mine Inspector in the Transvaal, under the Kruger administration. Since the above was written the elections in the Transvaal have taken place, with the result that the Boers are in control. Sir Richard Solomon stood for election as a Nationalist, of which group only six were elected. Het Volk, the Boer party, has 37 seats in the new Assembly, the Progressive, or British party, 21, the Labor party, three; and the Independents, two. As the Boers form a united party and the others are subdivided, the result has been that General Botha has been asked to form a ministry, of which he is Premier, with other leaders famous in the late war as members of his cabinet. Botha was on the side of reform long before Kruger was defeated, and as he proved an able military leader, he is likely to become a capable leader in Parliament In regard to the Chinese problem, it is probable that further importation will not be permitted, and that the anti-Chinese policy will prevail to the extent of the eventual re-patriation of the coolies.—Editor.]

DETERMINATION OF URANIUM AND VANADIUM.—In the usual method for separating uranium and vanadium, the former is precipitated as alkali or ammonium uranate, but the precipitate is gelatinous, and cannot be washed free from vanadium. The author describes a method in which the uranium is precipitated as ammonium uranyl phosphate. An amount of the substance containing not more than 0.25 gm. of uranium oxide, U_3O_8, is dissolved in sulphuric acid (1 : 5), and the solution evaporated till white fumes appear. After cooling, the solution is diluted, an excess of sodium carbonate added, and the whole boiled until the precipitate settles well. The precipitate is filtered off, washed with hot water, dissolved in the smallest possible quantity of sulphuric acid, the solution diluted, an excess of sodium carbonate added, and the whole again boiled. The precipitate is filtered off and washed, and the combined filtrates and washings are acidified with sulphuric acid. Ammonium phosphate (about 0.5 gm.) is next added, the solution heated to boiling, and made alkaline with ammonia, and, after boiling for a few minutes, the ammonium uranyl phosphate is filtered off, and washed with hot water containing a little ammonium sulphate. In the filtrate the vanadium is determined as usual by acidifying with sulphuric acid, reducing with sulphur dioxide, and titrating with permanganate. The uranium precipitate is dissolved in sulphuric acid, and the uranium determined in the ordinary manner by reducing with zinc and titrating with permanganate.—A. N. Finn, *Journal* Am. Chem. Society.

MINING AND METALLURGICAL PATENTS.

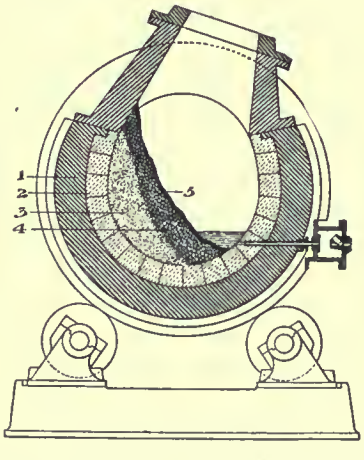
Specially reported for the MINING AND SCIENTIFIC PRESS.

GOLD-SAVING APPARATUS.—No. 846,483; James H. Leggett, Oroville, California.



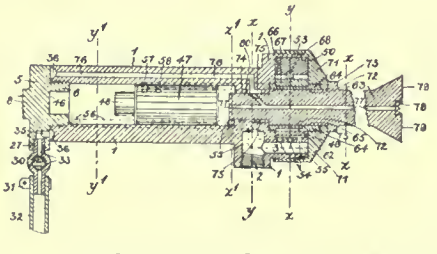
In an apparatus of the character described, the combination of a bucket-ladder and digging buckets, a movable screen for screening the material raised by said buckets, a pan beneath said screen, a grizzly located beneath the upper end of the bucket-ladder and adapted to catch the material discharged from the buckets and not reaching the screen, and a flume beneath the grizzly and connected with the pan beneath the screen.

METHOD OF RECOVERING VALUES FROM FLUE-DUST.—No. 846,818; Ralph Baggaley, Pittsburg, Pennsylvania.



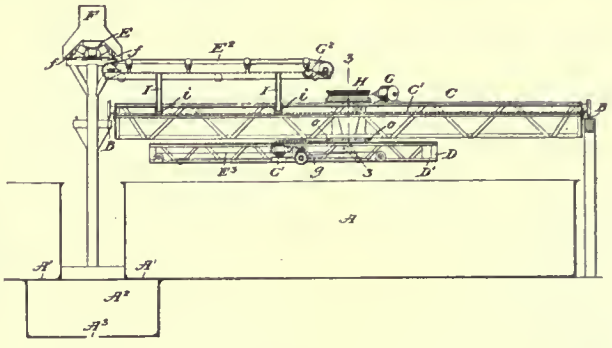
The method of recovering mineral values from finely divided value-bearing material, which consists in placing it in a converter, cementing it therein to the walls of the converter; adding molten matte; blowing air into the matte, and liquefying the dust thereby.

DRILL OR BIT ROTATING MECHANISM FOR ROCK-DRILLING MACHINES OR ENGINES.—No. 845,952; Henry Hellman and Lewis C. Bayles, Johannesburg, Transvaal.



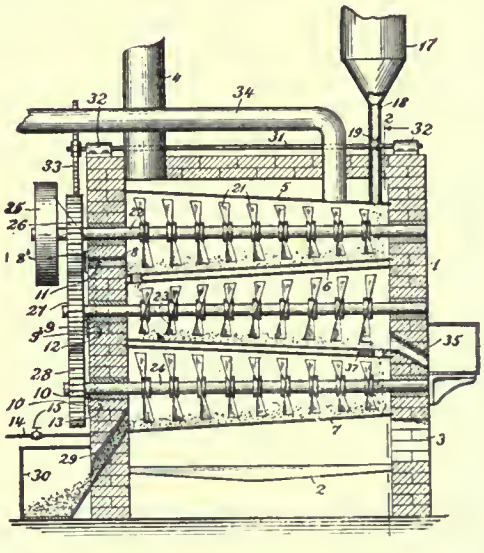
In a drilling or boring machine or engine, a power-cylinder, percussive apparatus within said cylinder, a drill or bit located at the forward end of said cylinder, a motor also located at the forward end of said cylinder, means for engaging said motor with said drill or bit, and means whereby the motor controls the distribution of actuating fluid in the power-cylinder.

DISTRIBUTING DEVICE FOR ORES.—No. 846,792; Joseph E. Kennedy, New York, N. Y., and Francis J. Hobson, Guanajuato, Mexico.



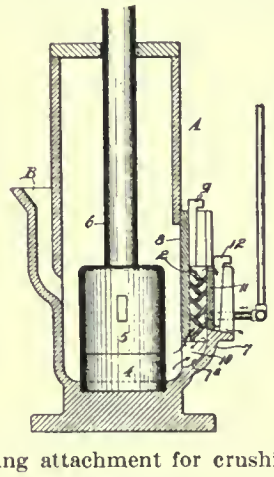
In a device for distributing finely divided material, a transverse beam or truss, a conveyor for carrying material to the centre of the truss; a revolving arm journaled at the centre, a radially moving conveyor carried by the arm for distributing the material, and a communication between the conveyor upon the truss and the distributing means.

PROCESS OF MAKING METALLIC OXIDES.—No. 846,444; John W. Bailey, Jersey City, N. J., assignor, by mesne assignments, to United Lead Company, a Corporation of New Jersey.



The process of making an oxide of a metal, which process consists in reducing the metal to an impalpable metallic powder and then slowly oxidizing the powder by heating it in the presence of an oxidizing agent.

CRUSHING MORTAR AND SEPARATOR.—No. 847,016; Hugh R. Logan, Carson City, Nevada.



An ore-separating attachment for crushing mortars said attachment including opposed series of oppositely inclined plates fixed vertically one above the other and having their lower ends overlapping and separated to form a vertically disposed tortuous channel for the discharge of the crushed material

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

E. A. H. T. sends an augite-biotite Diorite.

A. H. W., of Baker City, Ore., sends a specimen of volcanic Tuff.

The rock from Olalla, Canada, marked J. H. McD., is Diabase containing Pyrite.

The specimens from Temescal, sent by C. J. C., is an Epidote stained rock, of no value.

The specimens from Sheridan, Mont., marked D. G. D., are: No. 1, rock with Graphite scales; No. 2, Calcite; No. 3, Limestone; No. 4, Pyrite.

Specimens from W. L. B., of Manhattan, Nev., are. No. 1, Stibnite in calcite; No. 2, Realgar, the sulphide of arsenic; No. 3, altered Mica-schist.

The mineral from Los Angeles marked N. W. D. is Muscovite Mica. If in large sheets and perfectly transparent it would have a commercial value.

The specimens from Pilare de Nacozari, Sonora, Mex., marked T. N. S., are: No. 1, Feldspar-porphyry; No. 2, Andesite or Basalt; No. 3, Andesite; No. 4, Feldspar-porphyry; No. 5, Andesite; No. 6, Rhyolite; No. 7, serpentinized rock; No. 8, Cerussite, the carbonate of lead; No. 9, Feldspar-porphyry; No. 10, Quartzite; No. 11, Rhyolite; No. 12, altered volcanic, probably Rhyolite; No. 13, silicified Porphyry; No. 14, serpentinized Porphyry; No. 15, silicified Porphyry; No. 16, Andesite or Basalt.

LODE-FORMATION.—E. S. Simpson defined a West Australian 'lode formation' as a more or less vertical zone of rock, usually continuous with the surrounding rock, and of similar origin, but distinct from it in carrying metallic ores disseminated through it in payable quantities, and, as a rule, characterized by strong foliation. Deposits of this nature are probably deep-seated; at Kalgoorlie mining operations have already proved their persistence to 1,500 ft. below the surface. The typical lode formations probably owe their origin to a shearing action having crushed and foliated portions of a rock mass in a certain definite direction, producing a more or less well-defined band of rock through which, by virtue of the foliation, mineral-bearing solutions or vapors can have free circulation. In consequence of this, mineral deposits are formed within the rock, usually, but not necessarily, extending over the whole of the foliated zone, but seldom beyond it, and having no definite boundaries horizontally or vertically other than those determined by the decrease of the assay value of the rock in any one direction to a point at which it ceases to pay the expenses of working. Karl Schmeisser described them as 'composite veins.'

STRUCTURALLY there is great similarity between the gold deposits of Western Australia and the eastern part of the United States—the Appalachian belt. The lenticular shape is characteristic of both as it probably is of all such deposits formed during or before important epochs of dynamo metamorphism. There is a great difference between these veins and the clear cut, straight fissures of the California gold belt, for instance.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

One of two conflicting claimants made application for a patent. Thereupon adverse proceedings were commenced by the other claimant. For the purpose of settling and compromising the action a bond was executed by one party to the other, in which it was agreed that the person executing the bond should proceed as rapidly as possible to obtain a patent, and then to execute and deliver to the other party a deed of a part of the tract particularly described. After a demand and refusal, in an action for specific performance, a deed was executed to the tract described in the bond, giving its boundaries, the number of square feet contained therein, with the following additional clause: "Together with all the mineral therein contained. Together with all the dips, spurs, and angles, and also all the metals, ores, gold and silver-bearing quartz rock and earth therein, and all the rights, privileges, and franchises thereto incident, etc." After the date of the compromise agreement a secondary vein was discovered, which was distinct and separate from the discovery vein, the apex of which was between the compromise ground and the apex of the discovery vein of the person executing the bond. Under these circumstances it was held that the compromise and the deed was an adjustment of all sub-surface rights, and not merely the establishment of a surface boundary line between two conflicting lode-mining claims. In the course of the opinion the Court said: "While the bond made no mention of extra-lateral rights, yet in all probability it would have been held to pass them and the Court may have thought that the single specification 'all the mineral therein contained,' was liable to be construed as narrowing the conveyance so as to include only the mineral beneath the surface, and therefore required that there should be incorporated in the deed the words, 'together with all the dips, spurs,' etc. Yet, in requiring the introduction of these words, which in terms define extra-lateral rights, it also retained the phrase, 'together with all the minerals therein contained.' To the suggestion that giving this construction to the bond and conveyance is in effect the granting of a section of a vein of mineral, the answer is that there is nothing impractical or unnatural in such a conveyance. It does not operate to transfer the vein *in toto*, but simply carves out from the vein the section between the vertical side lines of the ground, and transfers that to the grantee. The title to the balance of the vein remains undisturbed."

Montana Min. Co. *v.* St. Louis Min. Co., 27 Sup. Ct., 254.

The requirement of parallelism of end-lines of lode-mining locations by the Act of 1872 cannot be deemed to apply where the location has been made at the time of the passage of that Act, and the proceedings under the Act of 1866 had then so far advanced as to exclude adverse claimants, in view of the various provisions of the latter Act for the protection of all rights previously acquired under existing laws, and of the provision that prior locators shall have "the exclusive right of possession and enjoyment of all the surface included within the lines of their locations, and of all veins, lodes, and ledges throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically, although such veins, lodes, or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side lines of said surface locations."

East Central &c. Min. Co. *v.* Central &c. Min. Co., 27 Sup. Ct. 258.

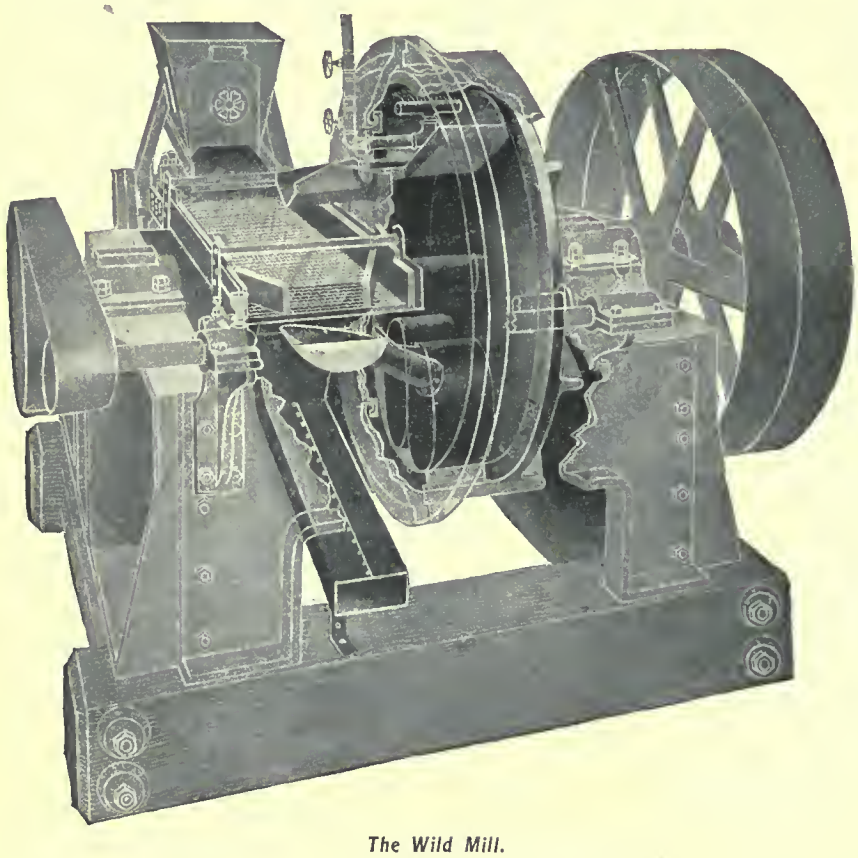
Where a statute required certain duties of a mine operator, without attaching any penalty, or providing any remedy for failure to comply with the statute, it was held that a mine operator was liable in an action at common law to an employee in the mine, injured in consequence of such a violation of the statute, and that such a regulation was valid for the protection of the public welfare and comfort.

Wolf *v.* Smith, (Ala.) 42 So. 824.

The Wild Mill.

It has been recognized for many years that there was need of a device whereby ores could be re-ground for concentration and amalgamation, without the excessive cost incidental to the use of stamps and re-grinding mills. The Morse Bros. Machinery & Supply Co., of Denver, Colorado, have recently designed a re-grinding machine, known as the Wild mill, which they claim will do this work, not only effectually, but at a reduced cost of operation. The machine is simple in construction, there being no complicated or intricate parts to get out of working order, but strong and rigid and capable of withstanding the roughest kind of treatment.

This mill, as will be seen from the illustration, showing the interior of the mill, comprises a feeder, a shaking screen, and a crushing mill combined, conveniently arranged and mounted on one base. The mill proper consists of a heavy revolving bed or ring-die, in which are placed two loose mullers or rollers, which obtain their crushing power from the contact with the revolving ring-die. This die is of



The Wild Mill.

rolled steel and is held in place by wedges. Each of the mullers has steel shells, which are also held with wedges. The action of these mullers is a blow and a grind at the same instant. The admission of the ore to the machine is into a hopper or feeder, which sets at the head of the mill, and is then automatically fed onto the head of a shaking screen. This screen is a Wild shaking screen, the motion of which is a forward and downward thrust, thus screening at each revolution and not permitting the screen to become congested. The undersize passes through, while the oversize passes over the end of the screen and into the spout, where it is then fed to the mill. The ore, after being fed into the spout at the end of the screen, is deposited directly in the path of the mullers and is crushed between these and the ring-die. The wear of the mullers and ring-die is true and smooth; being loose on the ring-die, they do not strike consecutively in the same place, causing them to corrugate, flange, or wear uneven. After the mullers have passed over the ore, the centrifugal motion of the machine carries it to the top of the mill, where a spray of water under 25-lb. pressure is constantly playing against the ring-die, breaking the momentum of the ore, which drops into the hopper and is carried through the spout or outlet, and deposited at the head of the screen It is then screened along with the feed, and that portion of the product which is crushed to the desired fineness at the first operation passes through the screen, together with the undersize of the feed and into the spout below.

By this operation, the machine is only working on that portion of the product that requires further grinding, and is not exerting its efforts in making slime, the quantity of which is reduced to a minimum; at the same time the machine makes a finished product that is as uniform as it is possible to obtain.

The mill does not require an elaborate foundation, but is simply mounted on substantial timbers and securely bolted thereto. The vibration of the machine is slight, its own weight being sufficient to retain it in alignment with the driving pulley on the line-shaft.

Trade Treatises.

THE JOSEPH DIXON CRUCIBLE CO., of Jersey City, N. J., has published an artistic little book on 'Crucibles: Their Care and Use.' The purpose of the book is to instruct users of graphite crucibles as to their proper care, and illustrates the effect of the use and abuse of crucibles by half-tones.

'Leyner Steam and Electric Geared Hoists,' is the title of Bulletin No. 510, sent us by the J. GEORGE LEYNER ENGINEERING WORKS CO., of Denver and Littleton, Colorado.

THE JOSHUA HENDY IRON WORKS, of San Francisco, has issued the following: Bulletin No. 100, describing the Pinder ore concentrator; No. 101, on quartz and gravel stamp-mills, with triple and quadruple-discharge mortars; No. 103, concerning standard ore and water-buckets, and wire rope and safety hooks; and Bulletin No. 105, describing water-gates, reservoir-gates, ball-joints, riveted sheet-steel pipe, pipe-line accessories, and hydraulic data. They are arranged in an attractive form, which is characteristic of all the matter sent out by this firm. This firm has also published a booklet entitled 'Notes on Black Sand-Tests,' by the hydraulic mining machinery department.

Commercial Paragraphs.

THE UNION IRON WORKS has opened a city office at 207 James Flood Bdg., San Francisco.

THE HEWITT MACHINERY CO., 37 Second St., San Francisco, report the sale of a 7 by 10 automatic single-valve Atlas engine to the Leland Stanford Jr. University.

THE AMERICAN SPIRAL PIPE WORKS, of Chicago, have taken over the entire business of the American Forged Steel Flange Company. In addition to a full line of flanges they made for their own pipe, they are now prepared to furnish steel pipe flanges for every class of work.

THE ABNER DOBLE CO., of San Francisco, is pleased to announce that the Appellate Court has affirmed the decision of the Circuit Court, upholding the non-infringement of the Dodd water-wheel bucket, patented June 23, 1891, and afterward assigned to the Pelton Water Wheel Company. About the same time this suit was brought covering the Dodd bucket, a similar suit was brought by the Pelton Water Wheel Co. against the Abner Doble Co., alleging infringement of the water guard used on the impulse wheels of the former. This suit also was dismissed by the Circuit Court, Judge Morrow holding that the Doble centrifugal water guard was not an infringement. This case was not appealed

Editorial.

ENGINEERS passing through London can obtain this journal from Leathwait & Simmons, at 5 Birchin Lane.

COMMENT ON our metal quotations has reached us frequently since we began to furnish the daily prices. These represent the average of actual transactions at New York on the date given, and they will be found to be trustworthy.

MINERS and managers of mines will find it interesting to read Mr. Whitman Symmes' articles describing how dynamite is made. It may be noted that the tendency is to use ammonium nitrate in the dynamite as a substitute for part of the nitro-glycerine. The manufacturers are feeling their way and testing the receptiveness of the public, which, of course, is not aware of this change in the composition of the explosive. There is no objection to the use of the ammonium nitrate; it gives less flame and is cheaper to manufacture, as it permits of the utilization of the weak nitric acid, formerly a waste product.

TO THOSE engaged in mining in Nevada, the bulletin on Goldfield will be most welcome. We publish a lengthy abstract, together with a map, from this geological report by Mr. F. L. Ransome. It represents the kind of work in which the Geological Survey excels, being a scientific treatment of matters closely related to actual mining, done by a geologist thoroughly versed in the study of ore deposits. In addition to his special knowledge of mining geology, Mr. Ransome is happily possessed of skill as a writer, not too much to render matter subordinate to manner, but enough to make his exposition clear and his description interesting.

TUNNEL SCHEMES are a lure for those ignorant of mining. Men of experience look at them askance. An adit that is planned to drain wet mines, like the Sutro tunnel, or one that is to serve as an artery for a large output of known ores, like the Ontario, the Cowenhoven, or the Yak tunnel, is a sound piece of engineering. But the idea of driving a long cross-cut into the heart of creation to cut lodes discovered at surface has been tried again and again without success. The most insiduous of such schemes is that which is planned to tap veins already worked in mines now abandoned, with the expectation of finding ore richer than that discovered near the surface. If a vein 'peters out' at fifty feet, or if it is poor at a hundred feet, it is neither sound logic nor sensible mining to spend a lot of money in order to tap it at 1,000 feet. Of course, if you make a drawing and represent a number of veins as pro-

ceeding downward uninterruptedly into the bowels of the earth, and then draw a horizontal line to represent the proposed adit, it does look as if you would have lots of mines—on paper. As a matter of fact, this sort of thing is the most illusive of all the imaginations conjured by the glamor of gold. But it serves to bait the circulars of irresponsible promoters. Before us lies a full page illustration taken from a contemporary. It gives a sectional view of a mountain penetrated—on paper—by an adit four miles long, and behind it is a fine panorama of Rocky Mountain scenery, with sunny peaks whose nobility of aspect puts to shame the sordid rot of this scheme to rob people. The 'tunnel' is to be driven—it is only on paper—to prospect at depth a particular portion of Clear Creek county, Colorado, that is least likely to yield rich ore, and that has been prospected at surface a great deal without any notable success. Other parts of the same county have proved richly productive, but in them such a scheme would be less likely to take root, because the mines have been more thoroughly explored, and less is left to the imagination. For after all, it is the imagination that makes the tunnel scheme so attractive to the simpletons in mining, and it is not the constructive imagination of the engineer or the scientist, who builds his mental pictures on facts and ascertained knowledge of the relations between facts, but the imagination of ignorance, soaring like soap bubbles and destined to a collapse as inevitable.

Salting Samples.

FOR ways that are dark the Heathen Chinee is not peculiar; there are others. Some of those ways are illustrated in the selling of mines; for instance, in 'salting.' This ought to be one of the 'lost arts,' but owing to the difficulty of legal conviction it survives through many changes of environment. Thus, this week we heard of a peculiarly elaborate trick. It was a gravel mine, in California, the yield of which was irregular and the value of which was uncertain; nevertheless, each time any engineer sampled it, he got good results by panning. Finally, the mine was sold; a new ditch was constructed and additional equipment was provided, in preparation for systematic work. The first trial proved the ground to be too poor to yield a profit. In the course of investigation, the explanation was discovered. The claim was owned by four brothers; whenever anyone examined the mine, it was the custom to pan the gravel in a side drift near the entrance of the 'tunnel' where there was a flow of water suitable for the purpose. The owners had driven an inclined drift and then walled it, but on the other side of the wall there was found a narrow passage that led to a point exactly above the place for panning; a small hole had been drilled through the 'hard pan' or cement, forming the roof at the spot where the panning was done, and through this one of the brothers had been in the habit of dropping the gold, which fell into the pan as the operator was busily washing the gravel. The particular tool, a short pick, with which the small passage had been dug, was found. There were so many of the brothers that one was never missed, if he occupied himself in the manner described. The others took the unsuspecting visitor through the mine and then stood a respectful distance away from him while he panned, so that the engineer felt positive as to the impossibility of any tampering with his results. Against the elaborations of such a nefarious scheme, there is apparently no defence except the removal of the gravel to a spot at some distance from the mine, to do which is likely to afford other chances for 'salting.' Thus we know of a mining engineer from New York who examined some dredging ground in Alabama, and owing to the lack of water, had his samples carried on a wagon to the nearest stream, getting results that were misleading, for the sufficient reason that all his samples were doctored by the driver of the wagon, at the instance of the owners of the claim. Another example may be quoted. An engineer now so well known that a daily newspaper would label him 'eminent,' examined the Vulture mine in Arizona, and took a number of samples carefully. The assays were satisfactory, almost too uniformly good. His chief arranged for a more detailed sampling before any payment was made to apply on the purchase of the mine, and a staff of samplers was sent to make a systematic examination. In the course of it, the suggestion of something wrong became manifest. A little detective work proved that the samples were being salted; a sack filled with coke was put where it could be tampered with, and the perpetrator was foolish enough not to notice the difference in weight, but enriched the coke with the usual allowance of gold. The salting was done with the gold precipitate from the zinc-boxes of the cyanide mill. An effort was made to get evidence for the prosecution of those responsible, but in this case, as in others, it was possible to convict the tool, but impossible to punish the principals. The moral of this incident is that an engineer should avoid accepting the assistance of men not wholly trustworthy, and never sample a large mine without an assistant of known integrity. As illustrating this point, we quote the story of an examination of the Martin White mine at the old camp of Ward, in Nevada, recently described in this journal. It happened thirty years ago, but the moral of it will apply as well today as then. It was a silver mine, and in the vein there were patches of loose manganese ore rich in silver chloride, affording a crumbly pulverulent stuff eminently adapted to the purpose of salting. An engineer came to examine the mine, and in his work he received the aid of a miner, who broke samples under his direction. The miner wore a coat with big pockets, and in them he had placed several handfuls of the black dust just described. He held some of it in the palm of his hand, and as he struck the vein with a pick he would let a little of the rich stuff drop with the ore detached from the vein. When this scheme did not work, he obtained another opportunity when sacking the sample, a pinch of the 'salt' finding its destination without much trouble. Never sample a mine alone. Write "*Caveat emptor*" on the front of your note-book, and on the back inscribe the proverb, "It is better to be sure than sorry."

By the Way.

Under the heading 'The Parents of Corporations' *The Evening Post*, of New York, comments upon the competition between States in the matter of licensing corporations. It says:

The point which is perhaps least considered in the warfare against corporations is that somebody created each of the pesky things, and turned them loose to plague us. Of course, everybody knows in a general way that some States cater to corporations more than others; but when a Trust exacts another penny, or our ribs are broken in a collision, it scarcely occurs to us to hold responsible the State which chartered the guilty corporation. The monster is so frightful that we forget all about Frankenstein.

The other day the Attorney-General of Kentucky began legal proceedings to secure the payment of a million dollars back taxes from the Southern Pacific Railway. That road at no point comes within three hundred miles of Kentucky. It does not even own property in the State. Yet Kentucky chartered the infant railroad, and expects to reap the benefit now. Nobody can tell from looking at the seal on a company's charter where it intends to do business.

In the *Central Law Journal*, Don Ensminger Mowry gives a brief account of the competition now going on between the States which want this corporation business, at any cost of fairness or self-respect. The familiar, standard corporation law, as he observes, is one in which "five men can sit around a table, put one dollar in the centre, organize a corporation calling for a million dollars' worth of capital, re-pocket the dollar, and go home after sending a certificate of incorporation to the Secretary of State, with a million-dollar enterprise ready to launch." It is from even this strict and hampering regulation that certain States have made concessions with a view to attracting corporations.

The legal press is filled with advertisements encouraging suspicious enterprises to avail themselves of the cheap cost, liberal laws, and freedom from liability which the particular State in question offers. Such conspicuous phrases as: "Incorporate in South Dakota," "The Corporation Laws of the State of Nevada offer the greatest inducements," and "We beat New Jersey," are not uncommon advertisements of our enterprising Western States.

In Delaware, Mr. Mowry's own request for information concerning the incorporation laws was referred by the Secretary of State to a private corporation engaged in the business of 'guaranteeing incorporations' for other concerns. The Secretary of State of South Dakota has given a letter of recommendation to such a concern in his State, saying that the papers it prepares "in all cases comply with the requirements of the statutes of this State."

The industrial promoter in these days stands in the position of the damsel of romance who demands proofs of devotion from her rival suitors. "Come live with me and be my love," cries New Jersey. "I ask of you only a brass name-plate, which you must affix to the front of some building in Jersey City. But one of your directors need reside in the State. You must pretend to have an annual stockholders' meeting here, but you need not come to it, because proxies 'go' to any extent you like. You need not even come over here to get your charter; an agent can secure it for you. And in exchange for these trivial duties and responsibilities I will protect you by avenging on outside corporations doing business here every insult or restriction that their States put upon you."

But New Jersey appears as a laggard in love compared with some of the other gallants. "Accept my name," urges Delaware. "You need not come here even for the annual meeting. You need not keep your records here. You can issue all the bonds you like without paying a cent of tax. Under my charter you can change your mind as often as you want to regarding your line of business. Incorporate a cheese factory, if you like, and if you decide later to turn it into a rolling-mill, or a gold mine, or a trust company—anything in the world except a bank—you have my permission. And besides all these advantages, my charter is the only kind in the country which is absolutely perpetual and unalterable, except at the instance of the party owning the franchise."

West Virginia's sighs are deep, but those young Lochinvars out of the West, Nevada and South Dakota, protest yet louder. Nevada charges no franchise tax. On a capitalization of a million dollars, New Jersey charges $1,000, Delaware $500, West Virginia $410, Nevada nothing. That sounds liberal when corporate purposes are unlimited and stockholders' meetings may be held outside the State. But South Dakota has made a bid favorable enough to get a thousand or more corporations a year away from all competitors. There no tax of any kind is imposed unless the corporation owns property within the State—an extremely unlikely contingency in any of these cases, of course. The entire expense of incorporation, including the maintenance of such an 'office' as the law requires, rarely exceeds $75, while "in nineteen cases out of twenty," on the word of a corporation charter company, "we are able to get the charter into the mails within ten hours after the application is received here." Thus the State which proposes to give up its divorce business, will still have something to fall back upon.

Speaking of similar matters, *The Mining Journal*, at London, says that the amendment to the Companies Acts, now before Parliament, embodies the opinion of the Departmental Committee of last year, that it is desirable to give more liberty to promoters and financiers in the interests of their business and, quite incidentally, of the Government's revenue. The history of the last ten years in company business is that the Government has been trying to raise more revenue from companies, and at the same time to protect the public from foolish or fraudulent finance, and in the result the revenue from stamps has suffered considerably. It has been urged that if the taxation were reduced, and notably the capital registration duty, business would revive, and the revenue would gain in the long run. The Government prefers, however, to keep up its tax, and is attempting to restore business by removing some of the legislative restrictions which at present hamper the company financier. With this end, the prospectus clause is to be modified, and in future information as to amounts of previous issues of shares or debentures, or of the commission paid in respect of them, is only to be required in the case of those made within the two years previous to the prospectus. The same time limit to disclosure is set for payments made to promoters, and it is no longer to be necessary to disclose the names of sub-underwriters. Clauses in the bill which legalize the issue of shares at a discount, and the payment of interest out of capital, are less revolutionary than at first sight they appear. In modern flotations, where the public first comes in at a premium, the insiders have, in the power to issue more shares at a lower premium, the practical equivalent of issuing shares at a discount. The proposed change will give the controlling groups of older companies the same useful power of selling out on the market in anticipation of a new issue when their shares are below par that they now have, so long as any premium remains.

Personal.

C. W. PURINGTON is at Paris.

GEORGE B. LEE is at Butte City.

W. H. WEED is at Morenci, Arizona.

JAMES W. ABBOTT has opened an office at Pioche, Nevada.

POPE YEATMAN was in San Francisco on his way to Los Angeles.

E. H. WEDEKIND is visiting San Francisco from Los Angeles.

CLAUDE T. RICE has left Bisbee, and is now at Los Angeles.

J. R. FINLAY is examining mines near Fredericktown, Missouri.

STRANGMAN HANCOCK has returned to London from the Transvaal.

J. M. CALLOW has returned to Salt Lake City from Telluride, Colorado.

E. MCCORMICK is engaged in professional work at Monterrey, Mexico.

A. W. WARWICK is supervising prospecting operations in Sinaloa, Mexico.

E. A. H. TAYS is engaged in professional work near Guaymas, Mexico.

H. WRIGHTSON, of New York, is visiting San Francisco, on his way to Nevada.

C. V. PETERSON, lately in Honduras, is visiting copper mines in Shasta county.

CHARLES A. CHASE, of the Liberty Bell Mining Co., is visiting California for a rest.

CARLOS W. VAN LAW sailed from Vera Cruz on March 29. He will be in Europe six weeks.

WILLIAM GOWLAND has been elected as president of the Institution of Mining & Metallurgy.

GEORGE A. TWEEDY, of Los Angeles, is superintendent of Minas del Tajo in Sinaloa, Mexico.

W. B. BRETHERTON, chemist for the Great Western Gold Co., at Ingot, Cal., is in San Francisco.

JOHN HAYS HAMMOND has been elected president of the American Institute of Mining Engineers.

CHARLES A. GREEN, of Mill City, Nevada, is visiting San Francisco, to dispose of antimony ore.

WILLIAM CAMPBELL has been promoted to be adjunct professor of metallurgy, in Columbia University.

EDWIN H. DAVISON is superintendent for the Anita Copper Mines Co. at El Cobre, in Sonora, Mexico.

T. C. MARTIN, editor of the *Electrical World*, has been elected president of the Engineers Club, New York.

WILLIAM B. MCKINLAY is serving as an assistant engineer on the work of the Interborough Rapid Transit tunnel in New York City.

J. A. DIGGLES has resigned as superintendent of the Vivian mine, in Western Australia, to become manager of the Broken Hill South.

HOWARD P. SAUNDERS, of Salt Lake City, has returned there from Humboldt county, Nevada, where he has been engaged in professional work.

HILARY BAUERMAN has been awarded the gold medal of the Institution of Mining & Metallurgy, in recognition of services in the advancement of metallurgical science.

W. H. LINNEY has resigned as manager of the Nipissing Mining Co., Ltd., of Cobalt, Ontario. Mr. Linney has been in charge of the operations of the company since its formation.

FREDERICK LESLIE RANSOME has been invalided by reason of an accident to one of his ears. He has been at Oakland for several weeks, and will soon be ready to resume work as an officer of the United States Geological Survey.

Obituary.

EUGENE E. BURLINGAME, a resident of Colorado for 42 years, and one of the best known assayers and chemists in the country, has passed away, after a long illness. Mr. Burlingame learned assaying in New York City, and went to Black Hawk and Central City in 1865, and three years later was appointed to the position of Territorial assayer. When his term expired in 1873 he went to Silver City, N. M., remaining there three years before returning to Denver, where he made his home and established the business which he conducted up to the time of his death.

Dividends.

On April 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 115 of $180,000. This makes the amount of dividends paid since January 1, $720,000, and total to date $8,586,000.

Mining Summary.

ALASKA.

JUNEAU.

The unsettled relations between miners and the operators of the Treadwell mines on Douglas island, have finally culminated in a strike being declared by Union No. 1. The employers refused to meet the men and discuss the differences, so 1,500 men are affected, all but 500 of whom belong to the union. Some threats to use dynamite were made, so a guard was installed on the property, and a detachment of Government troops has arrived from Fort Seward by special steamship.

ARIZONA.

PIMA COUNTY.

The directors of the Helvetia Copper Co. have recently visited the property. The smelter, which is operating at present, will be closed, and all attention will be paid to development work. The shareholders are principally Minneapolis and Boston men, and the company is well backed financially. The Isle Royal shaft, the deepest on the property, is down 900 ft. The company owns a smelter, and a narrow-gauge railroad between the smelter and the mine. ——The Helvetia district is suffering from a shortage of labor. Work on the Tip Top property of the Guggenheims is greatly retarded on this account, and 500 more men could find work in the district. The Tip Top continues to ship to El Paso.——Three tunnels are being run on the Omega property, and about 30 miners are employed in development work.

SANTA CRUZ COUNTY.

The properties of the Mansfield company, in the Wrightson district, are being surveyed for patents.——Development continues at the properties of the National Con. M. Co., on the west side of the Patagonia Mtn., and the showing is improving.

YAVAPAI COUNTY.

A force of 70 men is to be put to work on the property of the Consolidated Greene Co., having claims in the Walnut Grove district, 10 miles southeast of Kirkland, and it is said that the Calumet & Arizona Co. will shortly have a force of 25 men at work on their copper claims just beyond the Wesslich group.——The Neiman mine is yielding $32 gold ore from a two-foot lode at the bottom of the 80-ft. shaft.——Work has been resumed on the Triangle mine, situated three miles west of the Humboldt smelter, in the Big Bug district. The 400-ft. shaft will be sunk deeper, and work will also be done on the 350-ft. level.——The United Verde Extension Co. has installed a new hoist, boiler, and pump on the Little Daisy claim and intends to sink the shaft below the 300-ft. level.

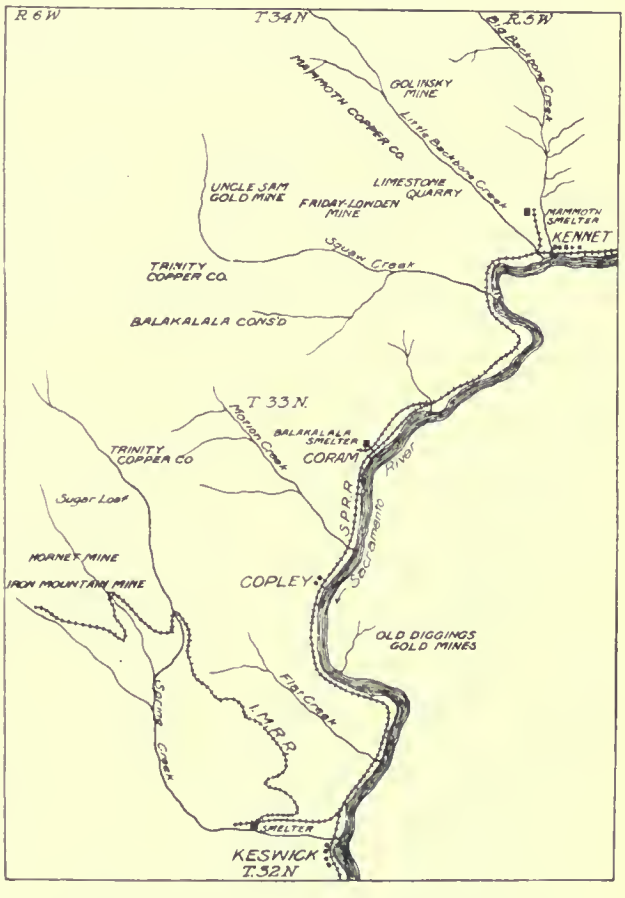
The Mt. Tritle Copper Co. has made its first shipment of ore from the Dunkirk mines to the Humboldt smelter. A contract has been let for hauling five tons per day from the mine to Prescott. The mines are opened by tunnels, and at one time produced gold, but the copper content has increased with depth.

CALIFORNIA.

NEVADA COUNTY.

The recent floods made a great deal of trouble in this county, and caused the suspension of operations in many of the big mines. Now, however, the Alta power line is again in operation; also the De Sabla and Rome plants. Many of the men were laid off, the mills closed down, but now conditions are better and the men are going back to work.——The mill at the Conlan property should shortly be in operation as the building is completed, the concentrators are in place and the other heavy machinery will be hauled to the mill as soon as the roads are passable. The mine is being pumped out after being badly flooded by the recent heavy rains.——The Empire mill was the first to start, since the general shut-down, but the operations were only intermittent, as the power was insufficient for a steady run.——The North Star has a good deal of pumping to do yet, before the mills can start.——Water continues to gain on the pumps at the Sultana mine, as the deep snow on Osborne hill is melting, and no mining can be done in this property for several weeks. Conditions are about the same at the Pennsylvania, which is badly flooded.

Every mine in the Grass Valley district is feeling the effect of shortage of electric power and the heavy flow of water. None of the mines are running full time or with full crews, and more men may be temporarily laid off.——The Jefferson gravel mines at Remington Hill, have been purchased by southern California men, and will be worked by the hydraulic method. The company will erect a large retaining barrier in Steep hollow, and will reconstruct the old ditch and flumes.——The first bar of gold from the Champion and Home mines since the shut-down two years ago has been brought to Grass Valley. Over 100 men are now employed at these mines.——The tunnel of the Giant King, near Washington, is in 300 ft. and has 700 ft. more to go before it will cut the lode. If the vein shows up well, a stamp-mill will be erected. The tunnel will be still farther



Map of the Copper Region in Shasta County, California.

extended, to cut two veins beyond the Giant King. It will be run so as to intersect the Crumbacker vein at a depth of 1,000 ft.——The surface-workers of Grass Valley have become affiliated with the Western Federation of Miners. ——It has become necessary to increase the pumping capacity at the Kenosha mine on Deadman's flat, and Cornish pumps will be purchased.——Smith & Dillon report that their asbestos mine near Washington will be worked. The asbestos occurs in a dike, in a gangue of amphibole.

SHASTA COUNTY.

The Keswick smelter could not start at the proposed time because of washouts preventing the shipments of limestone for flux. However, furnace No. 1 will be blown in very soon, while No. 2 will be held in reserve. Ore from the Iron Mtn. mine will be treated, and it will be at least two months before the branch railroad to the Hornet mine is completed. About 150 men are now employed by the Mountain Copper Co., at Keswick alone, and the whole town is booming.——Old Diggings is suffering from a food famine as the bridges, ferries, and cables have all been destroyed by recent floods, the only cable left being that of the Reid mine, which is used in transporting ore across the Sacramento river.——The Gold Leaf company in the Lower

Springs district, is building a two-mile tram to connect with the Southern Pacific at Middle Creek.——The Mountain Copper Co. has sent out a circular to the quartz miners giving the following schedule of rate on flux shipped to the Keswick smelter: Ore running from $3 to $15, 75% will be returned to the shipper, no smelting charge; from $15 to $25, 77½% will be returned, no smelting charge; from $25 to $200, 90% returned, $3.50 per ton, wet weight, smelting charge. Ninety per cent of the silver is paid for, if assaying over five ounces per ton. Ores running low in silica (below 90%) are subject to an additional smelting charge. All gold is paid for at the rate of $20 per ton, and silver on New York quotations at date of sampling. All ores must be delivered free at the company's works in lots of not less than 10 tons, an additional charge of $3 being made for sampling on all shipments less than 10 tons.

TRINITY COUNTY

The mill at the Bonanza King mine at Trinity Center will start at once. The aerial tramway that was wrecked early in the winter has been repaired, and is now in good working order. Joseph Porter is the superintendent.——The snow has gone from this district, mining activity is reviving, and 25 men are working at the Golden Jubilee on Coffee creek and at the old Nash mine.

The mines of the Trinity Center district are showing activity. Two 5-stamp batteries have been erected on the Golden Jubilee property, and 30 men are employed under William Chapman, the superintendent.——About 15 men are working in the Poverty Slide mine.——The Nash mine, at the head of Coffee creek, 15 miles from Carrville, will soon be worked again. Louis Maitland is the superintendent.

TUOLUMNE COUNTY.

(Special Correspondence).—The new shaft at the Confidence mine is down 370 ft., at which depth drifts are being run north and south.——A flow of water was encountered on the 200-ft. level of the North Star mine last week, which caused a sudden suspension of underground work. A pump was installed, and within a few days development work can be resumed.——Development work is being pushed at the Gem mine, near Sugar Pine.——Officials of the Kanaka G. M. Co. are expected to arrive from London shortly. The purpose of their visit is to inspect the Kanaka mine, near Groveland, and, it is said, to resume operations at the property.——A two-stamp mill will be erected this spring at the Never Sweat mine, situated near Columbia.——The recent inspection of the Black Oak mine, near Soulsbyville, is said to have been made for George Wingfield, a speculator from Nevada.——The Mountain View M. Co., with R. J. Gray as general manager, has been incorporated for the purpose of developing some mining property in the vicinity of Deer Flat.——At the property of the Cocktail Gravel M. Co., situated near Groveland, 300 tons of earth are being worked every 24 hours. No clean-up has yet been made, but the prospects obtained by panning indicate that the owners will be well rewarded.

Tuolumne, April 1.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The advent of spring has resulted in activity throughout the Georgetown district. Many old properties are again to undergo development and the camp is taking on an air of prosperity not witnessed since before the panic of 1893. On Douglas Mtn. the Amanda group of six claims is about to pass over to a syndicate of Eastern capitalists, the price being reported at $20,000. Past development has consisted in driving an adit for 700 ft., but as yet the Amanda vein has not been intersected. According to surveys the objective will be reached within 100 ft. and in view of the fact that a heavy production resulted from shaft workings, important discoveries are almost sure to follow. I. L. McLyman, of Georgetown, is to serve as manager.——The Douglas is showing strong, an 18-in. streak of lead ore having been recently uncovered. Driving is in progress, the ground having been opened for 30 ft. Shipments are to be started within two weeks. Assays show 38 oz. silver and 40% lead.——On Saxon Mtn., the old Morning Glory adit is being driven ahead. This was one of the first tunnel enterprises of the district, work having been first started over 40 years ago. The bore is in 900 ft., a number of veins having been already intersected. Drifts will be run to prove the ground, and it is expected to make shipments in the course of a few weeks.——Work will shortly be resumed on the Magnet group, also situated on Saxon Mtn. These holdings have a record of having produced over $2,000,000 from the shaft workings down to a depth of less than 600 ft.——At Empire, things are on the hum. The Gold Dirt, which has been a steady producer for a great many years, is showing large reserves of high and medium-grade ores. Nelson & Kermode are carrying a stope 300 ft. in length on an eight-foot streak of smelting ore which gives returns of 5.4 oz. gold per ton. A big body of mill dirt is showing, the product being shipped to the mill at Empire for concentration, the finished product bringing $60 per ton in gold.——Arthur Thoman is at work driving a drift on the sixth level of the same mine to cut under the C. C. Wilder shoot on the fifth level. An eight-inch streak is being followed which is worth $80 per ton. The ground being operated by C. C. Wilder is proving to be one of the best paying leases in the district. The orebody measures three feet across, and mill returns bring from 5 to 7 oz. gold per ton.——The Charter-Raton M. Co. is developing its holdings on Breckenridge Mtn. The bore has been advanced for 900 ft., three lodes having been intersected. As soon as the heading has been advanced far enough, driving is to be inaugurated. J. J. Bonner, of Idaho Springs, is general manager.——At the Jewell concentrator on Sherman Mtn., the finished lead product is worth $60 per ton, while the zinc brings $70. The mill is being run on dump-matter from the upper Mendota workings.——The water in the Mendota shaft has been lifted from the four lower levels and sinking is now under way. Contractor John W. Olds expects to complete the 300 ft. within four months. At that time cross-cuts will be run to catch the Mendota vein, when driving will be started.——Heavy shipments are still being made from the Silver Cloud and a handsome revenue is being obtained for the company. A stope 150 ft. long is carried and from 15 to 20 tons are broken daily, the average value of which is 70% lead and from 35 to 40 oz. silver per ton.——The Burleigh Leasing Co. is driving the west Phillips drift from the Burleigh adit. Progress is made at the rate of from five to seven feet per day and within 60 days the heading will reach the objective. At that time a raise is to be put through to make connection with the Seven-Thirty shaft workings. This raise will be 400 ft. but the workings above will be relieved of over 700 ft. of water.——The Strike made by Joseph Ebner in the upper workings on the Seven-Thirty vein is rapidly improving. Weekly shipments are being made and the value of the ore has advanced from $117 to $170 per ton in silver and lead.——John Schuler is stoping on a 10-in. streak of high-grade ore in the Bismark workings. The discovery was made in driving a cross-cut south from the Hercules adit to catch the hanging wall. Recent shipments brought returns of $90 per ton in silver and lead.——Albert Santo, owner of the Big Blue, is driving an adit and following a small streak of carbonates which assays well.——It is understood that the Centennial mine, situated within the corporate limits of Georgetown, is to be sold to a syndicate of Eastern capitalists, the consideration being given at $150,000. This mine is recognized as one of the greatest gold propositions to be found in Clear Creek county, and has a record of having produced $1,000,000. Operations are being carried forward 600 ft. below the level of town, and large reserves of high and medium-grade ore are showing. David Kennedy is the resident manager.——Work has been resumed on the Clyde property, situated on Leavenworth Mtn. The bore, in 500 ft., is to be advanced for a similar distance in order to intersect the lodes lying ahead. At one time the property produced ore of a high grade.——E. J. Butts, the manager, is still running the drift on the Good Hope lode, on Leavenworth Mtn. Some scattered ore is showing and it is believed that a rich pocket of ore is near at hand. Development work is proceeding on the Fred Rogers, operated by Mike Riley under bond and lease. A cross-cut is being run, as it was determined some weeks ago that the early operators lost the vein. In that event it is quite likely that this old

property will shortly be producing again.——Work on the Domino holdings, situated on Payne's peak, is bringing forth good results. Driving is in progress on the Domino lode intersected at a distance of 390 ft. from the portal of the adit and an 18-in. streak of galena is being followed which mills $80 per ton. Harvey Cochran, the manager, expects to install power-drills during the coming summer. An air-line will be run from the East Argentine M. Co. compressor-plant.——The strike made a couple of weeks ago in the Dewey adit in East Argentine is making a marked improvement. The streak now measures over 12 in. in width, with prospects of improvement. Driving is in progress, and as soon as the ground has been opened for 100 ft., stoping will be inaugurated. A. A. Ireland is manager. ——The Mohawk group, near Empire, has been transferred to the Accord M. & M. Co., which is being financed by New York capitalists. Lumber is being delivered on the ground and commodious buildings are now in the course of construction. Machine-drills are to be installed, and power will be furnished by the Two American Sisters M. Co., whose electric wires pass near the portal of the adit. The bore is now in 750 ft., two veins having been intersected. Arthur L. Carr, of Empire, is resident manager.——Another lode has been cut by the Annie May cross-cut on Columbia Mtn. The bore is now in 110 ft. and progress is being made at the rate of two feet per day. E. E. Grubb, the manager, states that a power-plant will be installed during the coming summer.——The Stemwinder still continues to send forth its share of the precious metals. Driving is still in progress from the level started from the 35-ft. shaft sunk from the lower adit, a streak of ore being followed which is 10 in. wide.

Georgetown, March 27.

TELLER COUNTY.

(Special Correspondence).—A corporation called the Cripple Creek Drainage & Tunnel Co. with a capital stock of 1,000,000 shares, par value of $1 per share, has been formed, with nine of the representative mine-owners of the Cripple Creek district acting as directors. This proposed tunnel will lower the water-level of the Cripple Creek district about 750 ft., and its portal is situated on the stream known as Cripple creek, and it is proposed to run it to a point near the El Paso mine, a distance of 15,000 ft., to cut the Beacon Hill water courses. If it is found necessary, it will be extended to a point near the Vindicator mine, a further distance of about 11,000 ft. It is estimated that the first section of about 15,000 ft. will cost in the vicinity of $400,000 and will take from two and one-half to three years to construct. The mines, railroads, and other interested parties have subscribed for a sufficient amount of the capital stock at par to build the first section, and they propose to subscribe for a further amount, if it is found advisable to build the second section. The company is now engaged in constructing buildings and installing machinery and otherwise arranging for active work.

Cripple Creek, April 1.

It has been decided by the management of the Gold Sovereign mine, on Bull hill, to sink the main shaft to a depth of 1,000 ft. The shaft is now down 900 ft., the last 100 ft. having only been recently sunk. Any discoveries of ore at this depth will not only be of great value to the Gold Sovereign mine, but also to adjacent properties, such as the Cresson and Trilby, into which the orebodies might extend. ——Some good-grade ore has been encountered at a depth of 1,500 ft. in the Findley mine on Bull hill. Calaverite shows in many places. This new discovery is of importance, as it has been made at the greatest depth to which tellurides have been found in the camp as far as is known. The output of the Findley mine approximates 100 tons per day, which is shipped to the Golden Cycle mill at Colorado City for treatment.——The compressor for the new drainage tunnel has arrived, and is being unloaded from the cars preparatory to being moved to the tunnel-site at Gatch Park. The machine is from the Chicago Pneumatic Tool Co., will operate 12 drills, and weighs about 15 tons. Owing to the weight of the machine it will be necessary to have the road repaired in places and the bridges strengthened.

Cripple Creek, March 31.

IDAHO.

IDAHO COUNTY.

O. Bosch has sold to George Brown a half interest in the Telephone Girl placer property, on the American river, near Elk City, for $10,000. This gives him control of the entire property, and he will begin operations shortly.——The McKinley company at Lucile is to erect a new mill. The Blue Jacket mines, eight miles from Lucile, are copper properties; 2,200 ft. of shaft and tunnel work has been done. Fifteen men are employed under F. E. Johnesse.——T. A. Simpson, who was sent into the Salmon River country near Lucile by Cœur d'Alene men, has made a strike on recently located properties. The find was made in a cross-cut tunnel, which proved the vein to be 18 ft. wide.

KOOTENAI COUNTY.

The W. K. Mining Co., owning two claims in the Pend d'Oreille district, near Rogers Siding, on the Northern Pacific, is installing a 10-h.p. boiler and pump to keep the shaft clear of water. A 25-ft. vein has been opened. The lode has two shoots, one of which carries zinc of a value of $75 per ton and the other $42 per ton gold.

SHOSHONE COUNTY.

(Special Correspondence).—The Snowstorm Mining Co. has ordered the payment of a three-cent dividend, amounting to $45,000, for March. It is the second dividend this year. It has been decided to pay dividends amounting to three cents per share every quarter. There is plenty of ore in sight to insure that amount for a long time, with a possibility of an occasional extra dividend.——The New Chicago group of two claims on the North Fork, above Pritchard creek, the first quartz location in the Cœur d'Alene district, is soon to be a shipper. The property is owned by Mrs. Eliza Heller and her son, George H. Heller. The mine is equipped with buildings, tracks, and ore-cars, and has been opened to good depth, where showings of carbonate and chloride are exposed. Three hundred tons of ore is sacked on the dump. The wagon-road will be extended to the mine at once, preparatory to making shipments.—— D. C. Hessian, manager for the Bitter Root M. Co., owning two groups of claims near Mullan, announced that his company has let a contract for 250 ft. of work on the tunnel, which is expected to reach the main vein when in a distance of 950 ft. W. T. Penrose, of Spokane, is president of the company, and a number of Spokane men are interested The company has the lode for three-quarters of a mile, and 700 ft. of tunneling has been completed.—— The Federal M. & S. Co. has begun a new prospect-tunnel, which will be run from Government gulch toward Wardner, more than 1,000 ft. There is ground there that has never been prospected by underground work, and it is believed that ore will be found.—— A strike of 10 ft. of copper ore is reported from the Iron Crown mine, near Lookout, east of Mullan. The strike was in No. 2 tunnel, in 800 ft., and at a depth of 300 ft. Albert Massing, John Anderson, and John Swanson are the principal stockholders of the company.—— A strike of galena ore is reported in the Hennessey-Burnes property, southeast of Burke. The ore was encountered by a new tunnel, in 120 ft.—— On the property of the New Hope M. Co., at Osburn, ore was encountered recently at the end of the tunnel, which is now in 700 ft.—— The lower tunnel on the Bull Pine property, on Two Mile creek, near Osburn, has opened a showing of mineralized quartzite impregnated heavily with galena.——The West Hecla Mining Co. has taken over the West Hecla group, consisting of the Bamboo Chief, Ophir, and Ruby claims, for $80,000, of which the first payment of $6,500 has been made. The rest is to be paid in 18 months. Subscriptions of $15,000 have been made to continue the development work. The group is in La Lande mining district, near Burke, and is an extension of the Hecla. A tunnel of 1,500 ft. will be driven with electric drills.

Spokane, April 1.

NEVADA.

NYE COUNTY.

A new find is reported on the Montana Midway Extension mine in Tonopah. A vein was cut at the 630-ft. level, showing two feet of ore. Some think the vein is similar to

the Montana Tonopah orebody, and the strike may prove to be of some importance, although it is very difficult to get reliable information.

ESMERALDA COUNTY.

The labor conditions at Goldfield remain practically unchanged. The Business Men & Mine Owners Association has issued a statement denying that it was formed to combat organized labor or overthrow the Western Federation of Miners. It reiterates that its purpose is to rid the community of the Industrial Workers of the World, and permanently settle the labor and business conditions of the camp. There is no intention of disturbing the present condition of hours and wages. The miners then held a meeting and appointed a committee to confer with the Association with a view to arriving at a settlement.

NEW MEXICO.

GRANT COUNTY.

(Special Correspondence).—There is a good deal of activity in the mines of this county. The old Beck mine has started up again, being now known as the National. The ore is silver bearing, with a little gold and occasionally a little copper. One shaft is down 310 ft., a second is 100 ft. deep, and another 60 ft. and there are several prospect shafts. The property is equipped with a good steam-hoist, and a 40-ton concentrating mill is running. About 1,000 ft. of work has been done underground, and the company owns ten claims, close to the Arizona line.——It is reported that the old Volcano mine will be purchased by Eastern men. The property consists of two claims, has a shaft down 300 ft., and is equipped with a 10-stamp mill and amalgamating pans.——At the Granite Gap mine, sinking is in progress, and some ore is shipped to Douglas and El Paso.——The Miser's Chest mine, near Lordsburg, has been bought by Eastern men and work has been resumed.——Most of the ore in this district occurs in contact zones, although some fissure veins are found. The country is badly broken, the evidences of volcanic activity being smoothed by weathering. The country rocks are andesite, granite, rhyolite, and limestone.

Steins, March 30.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Republic, Pearl Consolidated, Quilp, and Ben Hur mines have been leased to Harry L. Rodgers, of Butte, for terms of from three to five years, with options to purchase them upon certain conditions, among which is commencing work in the mines and building a mill about the middle of June, 1907. Mr. Rodgers has a new method of treatment for the dry ores of Republic camp, is confident of success, and expects to treat them for less than $3 per ton. Such success would revolutionize Republic camp.——The adit at the Winnipeg mine is in 835 ft. The foundations for a compressor-plant have been completed. A six-drill Leyner compressor is at the lower terminal of the Belcher Mtn. railway awaiting repairs on that road for delivery at the mine. Rand drills will be used. E. R. Fraser, has succeeded J. L. Harper in the management of the mine.——The Belcher Mtn. railway is now in charge of F. R. McMillan and undergoing alterations and repairs.

Republic, March 30.

STEVENS COUNTY.

(Special Correspondence).—Albert J. Goodell, manager of the smelter at Northport, announces that ores from Le Roi mines, part of which are now smelted at Trail, B. C., will soon be sent to Northport, for treatment. The factional fight has been settled, and hereafter all Le Roi ore will go to Northport. The contract with the Trail smelter is near its end.

W. H. Mead, manager for the Mining and Mammoth Mining companies operating at Metaline, reports that concentrating ore, carrying a high percentage of lead, has been struck. Assays show ore values up to $94 per ton. Ore was struck after the tunnel was driven 115 feet.——A body of ore, carrying gold and copper, has been cut in the lower workings of the Paragon mine near Northport. The ore runs 12% copper. The vein has been opened for five feet, but its extent is not yet determined. It is generally understood that F. Augustus Heinze is the principal owner of the property.

Spokane, April 1.

BRITISH COLUMBIA.

The group of claims belonging to the Spitzee Mines Co. has been leased and bonded by Le Roi Mining Co. A large force of men will be put to work at once on this property, which has already sent several thousand tons to the smelter. This is only another evidence of the tendency in this camp to consolidate properties. Air will be brought from the Black Bear, and A. G. Larson will be the superintendent.—The Nordberg compressor has arrived at the Centre Star, and is being put in place.—— The mines all shipped an increased quantity of ore this week, as the smelters are receiving plenty of coke again, and are running to full capacity.

The following is the tonnage shipped from and crushed at the Rossland mines for the week ending March 23: Centre Star, 2,791; Le Roi, 3,150; Le Roi No. 2, 350; White Bear, 35; White Bear, milled, 500. Total, 6,826. At the Trail smelter during the same week was received 6,446 tons. Besides the ore shipped to Trail from the Rossland mines, other shipments to this plant were as follows: Snowshoe, Phœnix, 565 tons; St. Eugene, Moyie, 336 tons; North Star, East Kootenay, 64 tons; Queen Victoria, Nelson, 45 tons; Sunset, 43 tons; Jessie Bluebird, 25 tons; Lorna Doone, 22 tons; Sally, 20 tons. The supply of coke is steadily increasing. At the Northport smelter, ore is still being received from Le Roi, but in a short time the contract with the Consolidated company will expire, and after that all the ore from Le Roi will go to the Northport smelter.

The shipments of ore from the Boundary mines for the same week were: To Granby smelter, from Granby mines, 13,641 tons; from Emma, 30. To B. C. smelter, from Mother Lode, 4,800 tons; from B. C. mine, 440 tons; from Emma, 100 tons; and from Snowshoe, 920 tons. To Dominion Copper Co.'s smelter, from Brooklyn, 1,954 tons; from Rawhide, 186; from Sunset, 480; from Mt. Rose mine, 70 tons. To Trail smelter, from Snowshoe, 660 tons; Sally, 30 tons; from Riverside, 30 tons. To Nelson smelter, from Emma, 20 tons. The total shipments for three weeks were 25,099 tons. The total shipments for the year to date were 194,503 tons.

This week the Boundary smelters treated ore as follows: Granby smelter, 14,628 tons; B. C. Copper Co.'s smelter, 8,070 tons; Dominion Copper Co.'s smelter, 4,058 tons. Total treatment for the week, 26,756 tons; and for the year to date, 190,036 tons.

NOVA SCOTIA.

(Special Correspondence).—Options on 18 different gold-mining properties in the Leipsigate gold mining district, the Malaga, Whiteburn, Pleasant River, Mill Village, and Brookfield gold mining districts, have been obtained by interests closely identified with the Micmac Gold Mining Co., and also an option on a 10,000-h.p. water-power site on the Mersey river, the purpose being to build an electric power-house, and run electric transmission lines to the different mines and mining properties under option.——If this plan is carried through, it will make it possible to work those properties which could not be worked under the old expensive methods, using steam for power, and coal and wood for fuel, and will give the mining districts in Queens and Lunenburg counties, the biggest mining consolidation in Nova Scotia. It will certainly make the districts of Malaga and Brookfield boom as the Leipsigate district is now doing.——The transmission company that is installing an electric transmission line from the power-house on the Mersey river to the Micmac mines, is erecting spruce and hemlock poles, instead of cedar, using 35-ft. poles, costing a little over $1 each. The cedar poles of the same dimensions would cost the company about $5 each landed on the ground. No. 6 copper wire will be used on the line, and 23,000 volts will be carried. Double apron, fog proof, heavy porcelain insulators will be used.——A great many of the miners who left Nova Scotia to go to Cobalt during the first excitement in that district, are now swarming back, on account of the unusual mining boom going on in this vicinity.

Bridgewater, March 21

Special Correspondence.

London.

Oroville Dredging.—Satisfactory Showing.—Economical Methods.—Mr. Hammon's Report.—Russian Mining.—Dredging in Siberia.—Sanguine Expectations.—Large Areas of Alluvium.—Glittering Generalizations.

The London committee of Oroville Dredging Ltd. has issued a useful report covering the period of 18 months, from the date when the Company began to operate, to January 31, 1907.

The following table is compiled from the general summary contained in the report of the general manager, W. P. Hammon, for the fiscal year ended July 31, 1906:

Number of Dredges	Property.	Ground dredged, cu. yd.	Average depth, ft.	Area dredged, acres	Gold obtained, $	Averages per cu. yd. Yield, Cents	Working Expenses, Cents	Net profit, Cents
3	Boston & California	2,161,981	31.0	43.19	406,769.35	18.81	6.37	12.44
4	Boston & Oroville	1,710,661	30.2	35.14	197,477.52	11.54	6.64	4.90
2	Oroville & Exploration	910,495	27.5	20.46	101,592.98	11.16	4.28	6.88
	Total	4,783,137	30 0	98.79	705,839.83	14.75	6.21	8.54

Of the above-mentioned dredges, 3 Boston & California, and 3 Boston & Oroville, old type, were at work throughout the year; 1 Boston & Oroville, modern type, began work only in May, 1906, and the 2 Oroville Exploration, old type, were at work for seven months, having begun operations on January 1, 1906. During the first six months of the current financial year—August, 1906, to January, 1907—the following dredges were at work: Boston & Oroville property; 2 Risdon, 1 Bucyrus, and 1 Boston Machine Shop (modern) type. Boston & California property; 1 Risdon, 1 Bucyrus, and 1 (old) Boston Machine Shop. These dredges were in operation throughout the six months. On Oroville & Exploration property 1 Risdon and 1 Bucyrus dredge throughout the six months, while the second (modern) Boston Machine Shop dredge started work on this property in October. In the same month work was begun on the Bear River property with 1 Risdon and 1 Boston Machine Shop dredge, the latter being the third modern dredge put into commission by Oroville Dredging Ltd. As the new dredges came into operation, with the increase in output and profit that naturally result, a satisfactory decrease is shown in the costs. Thus the total cost per cubic yard, which averaged 6.21c. during the year ending July 31, 1906, was brought down to an average of 5.19c. during the quarter ending November 30, 1906. Mr. Hammon's remarks on the first new dredge that was installed on the Boston & Oroville property in May, 1906, are noteworthy. He says: "This dredge was designed and built by the Boston Machine Shop Co. Dimensions of hull 100 ft. long, 38 ft. wide, 7 ft. 6 in. deep, contains 200,000 ft. lumber, digs 35 ft. below water-line; the bucket-line contains 66 buckets of seven cubic feet capacity; weight of machinery 646,000 lb.; speed of bucket-line, operating normally, 50 ft. per min., discharging 19 buckets per min. The dredge cost complete, fully equipped for operating, $95,409. This is the first machine of this design we have used, and the result for the first three months is very satisfactory. The ground in which it is operating is extremely hard and compact, and the fact that it has handled an average of 2,506 cu. yd. per day in ground where Dredge No. 2 could not accomplish over 1,000 cu. yd per day demonstrates its decided superiority over the older type machine. A longer period of operation will better determine its cost of operation, but the result so far obtained, of 3.83c. per cu. yd., is remarkable, and I have no hesitation in stating that such a dredge, under normal conditions, as to depths and formation, will handle material at a cost of at most 3c. per cubic yard." Referring to the results for the first fiscal year to July 31, 1906, Mr. Hammon reports: "As a whole, Oroville Dredging Ltd. has made its first score scarcely under average conditions, and, with the addition of three modern dredges, of great capacity, we should increase our yardage fully 50%, and we certainly will increase our output accordingly." And he states in conclusion: "The outlook for the future of our company is good, fully up to our expectations." It will be seen from the following figures that, with the addition of two out of the three modern dredges, during a part only of the six months to January 31, the general manager's anticipation as to increased returns was being realized.

THE LONDON COMMITTEE'S ESTIMATE OF APPROXIMATE PROFITS 18 MONTHS TO JANUARY 31, 1907.

Gross Returns.		Profits.
$ 705,839.83	One year to July 31, 1906, after providing for depreciation of dredges, etc.	$ 555,705.51
4 3,107.98	Six months to January 31, 1907	267,000.00
$1,178,947.81		$822,705 51
	Deduct dividends paid, namely, 5 quarters 12½c. per share to December 29, 1906	420,796.69
	Estimated surplus for reserve fund	$ 01,908.82

The Committee's report states further that a sixth dividend of 12½c. per share has been declared. This is payable at Boston on March 30.

Leading engineers such as Taylor & Sons, Frederick Hatch, T. H. Leggett, C. M. Rolker, are reported to be actively engaged in the investigation of properties, mostly in Siberia, on which options have been secured with a view to the formation of companies, some of which have a large working capital for development of concessions, extending over many thousand square miles, generally described as "auriferous territory." Numbers of Englishmen and Russians are found exchanging visits to each other's capitals in quest of concessions on the one hand and financiers on the other. As a result a good deal of money is beginning to flow from and through London to Russia. One of the newly formed companies—Central Siberia Ltd.—has been spreading its glittering wares before the public at the first (statutory) meeting under the presidency of the Marquess of Winchester, chairman of the company. Referring to the properties in the Yeniseisk district, the chairman reminded the stockholders that Mr. Maund (the managing director) and Mr. Mercer, (the consulting engineer) had made a careful examination of those properties during the last summer and autumn. The board had since then had the advantage of consulting with Mr. Vostrotin, from whom options over many of the properties in the Yeniseisk district had been obtained, and they had learnt from him that over 17,250,000 oz. gold had been taken out by pick and shovel alone in the past in that district, so that it was no untried proposition, but really a going concern that has been successfully carried on in the past by primitive methods, and which, by the introduction of modern machinery, should be more highly remunerative. It is expected that the first profits will be realized from the Kalami river group. A dredge of approved English make has been secured, capable of dealing with 1,500 cu. yd. of wash per diem, and a contract has been entered into that will ensure the commencement of gold-dredging operations in August next. The Company's engineer is shortly leaving for Siberia with a dredge-master, who has had experience in New Zealand and elsewhere, and a competent staff to superintend the erection and working of the dredge. The chairman gave the engineer's views

on the profits which he anticipates they are likely to derive from the working of the Alexandrofski group by dredging, in the place of the old hand-work. He states that, taking the total dredgable contents of the Alexandrofski property—one of the group where they are starting operations, and where the investigations were conducted last year—at 8,000,000 cu. yd., having an average value of 1s. 8¾d. per cu. yd.; the total recoverable value is £691,666, but, by the subsequent acquisition of adjoining properties, the total dredgable length on the Kalami river is alone increased to 10 miles, giving a total dredgable contents of 26,000,000 cu. yd. Valuing this at no more than 1s. 6d. per cu. yd., the total gold value is £1,980,000, recoverable at a cost of £742,500, leaving an ultimate net profit of £1,237,500, and this after allowing 6¾d. for working costs; this liberal estimate having been arrived at in view of the extra work entailed in the removal of boulders found in the turf.

Turning to the Timofeesky property, which has produced in the past, from a portion of the area worked, 15,800 oz. gold, situated on the river Vangash, in the North Taigah district, the engineer states that on this property the wash is about 16 ft. thick, with an overburden 8 ft. thick, and he considers it will be fair to take the value throughout at 1s. 2d. per cu. yd. The total dredgable ground is estimated at 7,300,000 cu. yd., having a total value of £426,344, recoverable at a cost of £152,344, leaving a profit of £274,000. On the subject of the vein-mining properties, the chairman explained that this branch of the industry in this district had been entirely neglected in the past, owing to the ease with which the alluvial gold was won, and to the utter ignorance as to how to deal with quartz propositions. In the opinion of the engineers and geologists, the gold found in such abundance in the alluvial deposits has been derived by the denudation of quartz veins. As evidence of this, the boulder of quartz before the meeting seamed throughout with gold, was brought by the expedition from a river in the company's district. From the veins, to some extent prospected by them, the Pervenetz, which is situated close to the alluvial properties, claimed attention. This vein has been merely exposed on the sides of the hill; but it can be rapidly developed at a minimum expenditure. The engineer states that the vein is about three feet wide, and that samples gave the satisfactory result of nearly 19 dwt. per ton. Arrangements have been made to erect a small stamp-battery on this property. Another vein, the Gerassimo, was first visited by Mr. Mercer some 17 years ago, and has already been subjected to a certain amount of development. Its past history has shown that, notwithstanding the crudest methods of work and management, it has produced no inconsiderable amount of gold. Investigations undertaken by the Government upon work done as far back as 1890 give assays as high as 2½ oz. per ton, with an average of 14 dwt. Taking into consideration the facilities for working and the great size of the lode, it is estimated that ore of no higher value than 8 dwt. per ton will yield a profit of 12s. per ton when everything is equipped and organized. In summarizing the whole of the Company's holdings in the Yeniseisk district, it was found that the total dredging area in the North Taigah is 7,669 acres and in the South Taigah 1,225 acres, or a total of 8,894 acres. The figures and values for the Alexandrovski, or Kalami group, and for the Timofeesky, show that nine dredges working on these two properties would give an aggregate profit of £75,000 per annum, with an average life of from 15 to 20 years. Much has been said about the climatic difficulties in Siberia; but it has at least the advantage of being extremely healthy, and as regards quartz mining, it can certainly be carried on all the year round, while dredging in the North and South Taigah, where there is actually no permanently frozen ground, can be usually carried on for an average of 155 days. The managing director, Mr. Edward A. Maund (of South African mining fame) in addressing the meeting said he wished to emphasize the fact that they were the holders of 57 mines in the Yeniseisk district. He then spoke of the important interests of the Company in the Transbaikal district, and wound up an eloquent speech by reminding his audience that Russians could afford "to forget outlets in the Indian Ocean, the Far East, or Mediterranean, for Russia possesses within its own frontiers all the riches not owned by other nations. Russia has no need—like other nations—to go across the seas to found colonies." This was a solid fact, brought home to anyone who knows Canada and British Columbia and has seen Siberia. "She has, in fact," said Mr. Maund, "Australias, South Africas, Canadas, and Klondykes within those frontiers. It is well that this company obtained a share of Siberian riches while the welcoming hand was extended alike by the Government and a thoroughly hospitable and friendly people."

Spokane, Washington.

Copper Mining in the Coeur d'Alene.—The Snowstorm Mine.—Other Promising Copper Prospects.—Two Classes of Ore.—Metallurgical Treatment.—A Copper Smelter Likely to be Built.—Canadian Coke.

In the past the Cœur d'Alene district of Idaho has been chiefly noted for its large production of lead ore, but in the future the tonnage of copper ore promises to become an important factor. The success achieved by one mine, the Snowstorm, three miles east of Mullan, has directed a large amount of attention to the possibilities in this direction. From one mile east of Mullan to 15 miles east, the ore-bearing quartzite, instead of maintaining the usual lead production, is copper-bearing, with a distinct dividing line between the classes of copper mineral as adapted to smelting. For simplicity, the Northern Pacific railroad may be taken as this dividing line. North of the railroad, the ores are silicious, running 90 to 95% free silica. The main shipping product of the Snowstorm and also of the other prospects, down to 750-ft. depth, is a copper carbonate, running from 3.75 to 8% copper, on the average. Below 750 ft. the ore changes to a highly silicious chalcocite, with some bornite and chalcopyrite. In a smelting sense, the ore can be classed as silicious all through. With greater depth in the Snowstorm, the percentage of sulphides appears to increase, both in amount and in the size of the particles, but concentration may be said to be not feasible, as long as a market can be found for the ore by mining and shipping the vein in its entirety. The expense of the plant required, coupled with the losses in ore-dressing, would outweigh the benefit derived from the saving in freight charges on the waste-matter shipped. The ore is chiefly useful for converter-lining, due to its low iron and high silica contents, which fact must also be taken into consideration in the treatment rates quoted, as against the saving in freight. There is every indication that, with depth, the prospects under development on the north side of the railway will be of the same nature as the Snowstorm. The market for this class of material is a limited one, wherefore, should other mines reach the shipping stage, these would become active competitors.

South of the Northern Pacific railroad, and directly opposite the north side, the character of the ore changes into the sulphides, chalcocite, with large particles easily treated in ore-dressing, chalcopyrite, and bornite also in the same class. The accompanying minerals are siderite and iron pyrite. The matrix is a quartzite with small

veinlets of quartz. As a concentrating mixture, it is fairly good, and there should be little difficulty in arranging a flow-sheet that will throw the major part of the ore-dressing onto machines of large capacity, such as the Hancock jig. The water supply is excellent; electric power is available and cheap. Chalcopyrite predominates as the copper producer; the mineral is fairly hard, and will resist the abrasion so productive of slime in machines of great capacity. No zinc or barite is encountered. The properties are as yet in a preliminary stage of development, but a number are being worked in a vigorous manner, and the indications to date show that the orebodies are of large size, they can be mined and transported cheaply, and sampling indicates that they will easily average two per cent copper in the mill-feed.

The only mineral that remains an uncertain factor is the siderite. This occurs in considerable quantity, and the closeness in specific gravity to the pyrite and copper

The Coeur d'Alene, Idaho.

sulphides renders this mineral difficult to remove in concentration. The admixture of the siderite in copper smelting is not wholly a desirable feature, due to the evolution of the carbon dioxide, which tends to extinguish the flame in the copper furnace. This phase of the problem should not present any great difficulty. It might necessitate roasting, but the ore would be rich enough to stand this extra expense.

The operators on the north side fully realize the gravity of the situation with relation to the silicious product. It is to a large extent their capital that is developing the south side properties. With the proving of the latter, the next step will be the establishment of a smelting industry, situated at some favorable point. Iron is abundant, fuel can be procured cheaply from the Canadian side, at no greater cost to the plant than that furnished by the Utah and Colorado plants, and probably as cheaply as that now received by the Anaconda and Great Falls smelters. Limestone of good quality exists contiguous to the Cœur d'Alene district. Abundant water and power, rail competition, and labor are within touch. Every indication points to the establishment of a large metallurgical industry.

As for ore supply, the Snowstorm alone is capable of furnishing up to 750 tons of silicious ore per day. Other properties on the north side are likely to become shippers within a year. The necessities of the silicious tonnage bid fair to force the development of the south side sulphide belts. A copper smelting industry is fairly in sight for the Cœur d'Alene, which will vastly increase the importance and scope of operations in this magnificent mining region.

Salt Lake, Utah.

Utah Consolidated Earnings. — News From Bingham. — The Tintic Smelter. — Ore Shipments. — Deep Creek District. — Smelter Sites.—The Ontario Adit.—Utah Copper Co.'s Mill.

An extract from the annual report of the Utah Consolidated Mining Co. shows the earnings of the Bingham mine belonging to this corporation during 1906 to have been $9.45 per share net, on a production of 18,500,000 lb. copper. During the year 296,989 tons of ore underwent treatment, yielding aside from the copper, 457,812 oz. silver, and 42,601 oz. gold. The net profits were $2,835,009, against $1,887,385 recorded for the previous year. The amount of sulphide ore in sight is reported to be about the same as twelve months ago. A total of 10,172 ft. of exploratory work was performed, 2,725 ft. of which was in ore. This development was done largely on the upper levels.

A suit has been filed in the District Court by Richard F. Smith against the Bingham Group Mining Co. and others to quiet title to the Crœsus claim at Bingham. It is alleged in the complaint that defendants have attempted to place a mortgage on the property for $30,500, thereby clouding the title. Damages to the amount of $5,000 are demanded. At a special meeting of shareholders of the Bingham Standard Copper Co., a bond issue of $125,000 was authorized. A resolution was also passed sanctioning the action of the directors in bringing about a plan of consolidation with the Bingham Central Mining Co. The Consolidated corporation will own over 500 acres of ground.

It is expected that excavations for the lead smelter to be erected by the Tintic Smelting Co., will be started within two weeks. The plant will have a capacity of about 250 tons per day. Two stacks will be used in the first unit. The site will be near the town of Silver City. The ore shipments from the Tintic district last week amounted to 148 carloads. The mines contributing and their respective amounts were: Ajax, 1; Beck Tunnel, 9; Bullion Beck, 8; Bullock, 1; Centennial Eureka, 53; Carisa, 4; Eureka Hill, 9; Eagle and Bluebell, 7; Grand Central, 6; Godiva, 2; Laclede, 1; May Day, 5; Mammoth, 6; Ridge and Valley, 3; Scranton, 6; Swansea, 6; Star Con., 4; Tintic Iron, 3; Uncle Sam Consolidated, 5 carloads.

The Beck Consolidated Mining Co., has begun excavations preparatory to the installation of a new hoisting plant. The Lower Mammoth Mining Co. has its two new hoisting plants in operation, and is shipping ore which lets a profit of about $11 per ton. The Mammoth Mining Co. has made a shipment of copper ore from the 2,260-ft. level; this will average 11%, with additional value in gold and silver.

Two judgments have been decreed against the Sheba Mining Co., with property in the Deep Creek mining district. One of them is for $23,444; the other for $9,475. The property has been ordered sold by the Court to satisfy these judgments.—— Conditions at the May Day mine are reported to be very encouraging. A raise on the 400 level has opened a 10-ft. breast of ore carrying 40% lead, and 20 oz. silver.——The Jennie Extension Gold Mining

Co. has been organized to develop a group of claims at Gold Springs, Iron county. The officers are: F. R. Davis, president; C. A. Short, vice-president and manager; H. R. Elliot, secretary and treasurer. The headquarters will be at Salt Lake City.—— It is expected that the new mill recently installed by the Jennie Gold Mining Co., at Gold Springs, will be in operation within a week. It will treat about 40 tons of ore per day.

The Governor, John C. Cutler, has disapproved the bill passed by the late legislature giving to smelting companies the privilege of condemning land within a radius of four miles of smelter sites. The executive holds that the bill was in the nature of class legislation, and therefore unconstitutional.

The management of the Consolidated Mercur Gold Mines Co. is making a normal production again, after having been handicapped for some time by a fuel famine and other difficulties.——The development of the Ingot mine at Mercur has been resumed. The property has been idle for several years. The Frisco Contact mine in Beaver county is being operated. The property was recently equipped with a steam hoisting plant.

The task of unwatering and reclaiming the Ontario and other mines at Park City is progressing slowly but surely. The three-mile drainage adit is now pretty well cleaned and repaired as far as Ontario No. 3 shaft. It is believed that the only remaining obstruction lies between shafts No. 2 and 3. The adit was closed on account of caves over two years ago.——The West Quincy Mining Co. of Park City has been prospecting its ground for several months with diamond-drills, and has encountered a contact vein, which is believed to be an extension of the old Quincy vein opened in the territory of the Daly-West Mining Co. The West Quincy Co. will sink a permanent working shaft.

The starting of the Utah Copper Co.'s concentrating mill at Garfield is likely to be delayed for several weeks for the reason that the Rio Grande Western railroad will not be in position to keep it supplied with ore.

Mexico.

Dividend From the Amparo.— Japanese Labor.— Hostotipaquillo District.— El Favor.— Mining in Oaxaca.— The Taviche District.—New Power Plant.—Smelter at Magdalena.—New Enterprises in Tepic.—Lluvio de Oro.

The annual report of the Amparo Mining Co., of Philadelphia, owning and operating the Santo Domingo and adjoining properties, about six miles south of Etzatlan, in the State of Jalisco, showed a profit for the year 1906 of $583,945, and a dividend of 3% (the first declared by this company), on its capital of $2,000,000, was paid on January 31 of this year. It is the expectation to make this 3% dividend quarterly. The great reserve from the 1906 earnings was retained for the purpose of paying for a number of needed improvements, chief among which are the three-compartment shaft, which is now being sunk; the 40-stamp 140-ton concentration and cyanide mill now in course of construction, and the 5,000-ft. aerial tram to lead from the mine to the mill, both of which it is expected to have in operation this coming June. This company is the pioneer in the introduction into this district of Japanese labor, and it is claimed that such Japs as have remained have given entire satisfaction, though about 40% of the entire number brought in have shipped out again, presumably for the United States.

The great success of the mines in the State of Sinaloa under purely Mexican management, after having been abandoned by their American owners, is somewhat of a blow to American pride. Natives lose no opportunity of pointing to San José de Gracia as an example of what Mexicans can do in mining. The former American owners took out many millions during their possession of the property. The insistence for large dividends and the lack of keeping prospecting ahead of mining brought the inevitable. A time came when prospecting had to be conducted without revenue from the mine. Tiring of this, and against the urgent advice of the manager, the property was sold to the former Mexican owners, who have reaped great profits from new discoveries. The mills are in steady operation and about 400 men are employed.

The Sierra Madre Mining & Devolpment Co. has started work on its properties near Madriles and at Sabinito. Both are in the district of Falite in the foothills. The property at Madriles created some excitement when discovered, owing to the exceedingly rich specimens of native silver found. The properties at Sabinito are *antiguas* with free-milling gold ore. The company is also examining other mining property with a view to purchase. A. W. Warwick is consulting engineer.

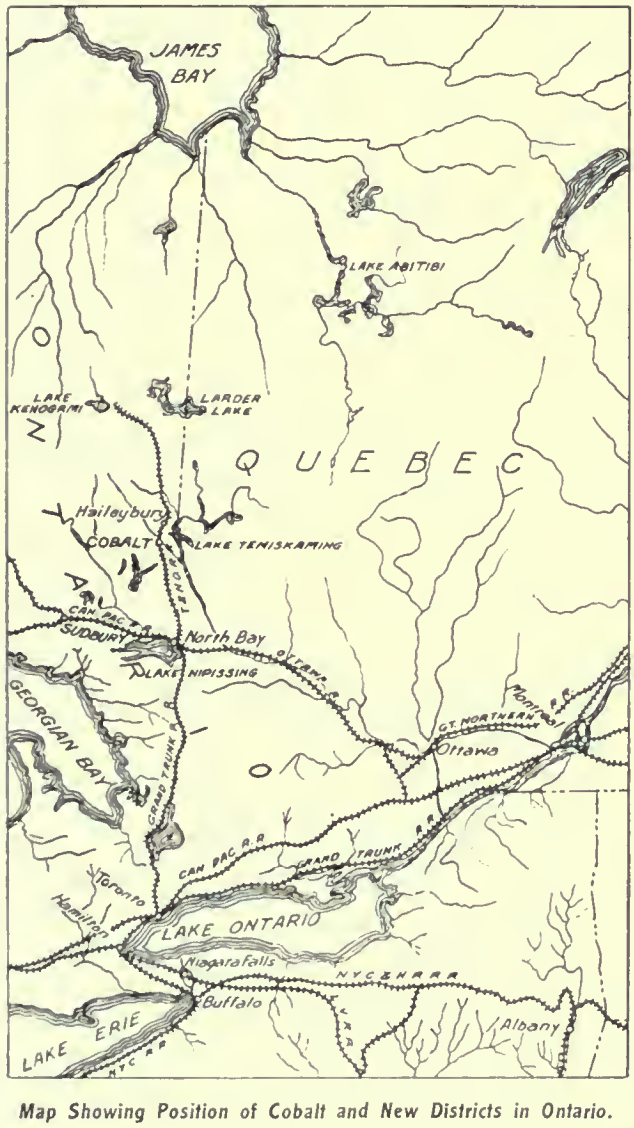
The Lluvia de Oro Co. will shortly have one of the most complete mining and milling plants in the State of Chihuahua. A mill is being erected of the most solid construction and from designs made in accordance with the experience gained during the last five years' milling practice. The great difficulty in Mexican mining is that of transportation. This has been entirely overcome by the management. Roads of really fine character have been laid out and built. These reflect the greatest credit on the engineering skill of the manager. The country is one of the most rugged on the west slope of the Sierras, yet the maximum grade of the roads is only seven per cent. Recently a large number of American artisans arrived at the mine to complete the construction of the mill. Several hundred mules are engaged in carrying the machinery. This mill will be in operation in about ten months. Robert Coleman, the consulting engineer, is at the mine personally directing the work.

North from Etzatlan, in the Hostotipaquillo district, Sanford McKeever, president of El Favor Mining Co., has leased for his company for a period of five years the old Hacienda de Pietro (an old *patio*) where a small testing plant for concentration and cyanidation will be installed, and as soon as the correct treatment has been determined the initial 100-ton mill will be erected on a suitable site. In the meantime the *arrastre* and *patio* will still be used on certain grades of ore. Most remarkable and unexpected bodies of ore have been opened up in the workings of El Favor in the last few months, proving beyond doubt that they are on the extension of the old Mololoa vein, and it is probable that the past bonanzas of the Mololoa (now being worked by Carlos Romero, of Etzatlan) will be equalled, if not surpassed, by El Favor when the latter begins mining, for as yet only the ore encountered in the development drifts and cross-cuts has been taken out.

The new mill of the Calabacillas company is in operation. Regular shipments of bullion are being made. On the lowest level a body of ore of high value has been encountered. Originally acquired as a low-grade mine, the Calabacillas bids fair to be a true bonanza. Several hundred men are employed. The mill of the ill-fated Oro Fino has been purchased by the Calabacillas, and is being moved to the latter mine. A. J. Underwood, who is largely interested financially in the mine, has personal charge of the property.

The name of the Mazeppa Consolidated Mining Co., adjoining the Cinco Minas of Martinez and Cardona, in Hostotipaquillo, has been changed the Aguila Amalgamated Mining Co., with J. B. Neily, of Boston, as president.

Among the new companies to start operations in the State of Oaxaca is the San Martin y Anexas Mining Co., organized with a capital of 400,000 *pesos*. Henry Lockhart, Jr., is president, and F. M. Leonard is general manager. The company is to take over and operate some 55 *pertinencias* in the San Martin district, 50 kilometres south of the town of Oaxaca, and only one mile from the new railroad. A good body of high-grade silver and gold ore has been opened up, and the company is prepared to expend $100,000 on machinery and improvements, among which will be a new hoist and pumps, and a 10-stamp mill.—— In the Providencia-San Carlos, of the Taviche district, a promising body of ore, assaying 8 kg. silver and 9 gm. gold per ton, has been encountered in a cross-cut from the 190-ft. level; and



Map Showing Position of Cobalt and New Districts in Ontario.

while this cross-cut was being driven a new boiler, hoist, compressor, and pump have been installed; the shaft will be sunk an additional 200 ft. The Rosario, in Taviche, is being unwatered and sinking has been resumed, and at the Nujeres property, also in Taviche, has started a new shaft and is continuing its adit toward the Escuadra, one of the richest properties in the district. G. W. Thompson has obtained control of La Tehuana Mining Co., and it is understood operations will be resumed at once.——A. P. Appelwhite has obtained a concession for a power-plant on the Rio Grande, near Cincatlan, for distribution in the Oaxaca and Taviche districts.—— Lloyd R. Hamer and associates seem to be meeting with unusual success at their little lead smelter at Magdalena, Oaxaca which has been running without interruption since its inception last summer, shipping its bullion to Europe. ——It is understood that the Taviche plant of the Oaxaca Smelting & Refining Co., on which the work of construction was stopped last fall, has made satisfactory arrangement with the mines, either by contract for the ores, or lease and bond on the properties, and has obtained the required additional capital, so that work will be resumed as soon as the machinery has been delivered.

Louis Fontz and Wm. Leonard have, through Wm. H. Lees, of Guadalajara, interested Chicago capital in the old San Jose de Ventanas property, in the Jora district of Tepic, about 10 hours' ride west of Hostotipaquillo, Jalisco. The new company will be known as the Cuatras Mining Co., of which Harry M. McIntosh, of Chicago, will have control, and Wm. H. Lees will be resident manager. The San Jose de Ventanas is one of the oldest properties in that part of the country, and was at one time owned by Tomas Treviño, one of the first owners also of the Mololoa, of Hostotipaquillo, now being worked by Carlos Romero, of Etzatlan. But the workings had been abandoned for years, and have just recently been unwatered by Fontz & Leonard, so that little can be said at present of the underground showings, though the old dumps, of which it is estimated there are something over 500,000 tons, give some indication of what has been produced, and a 30-ton experimental cyanide mill is to be erected for treating these old dumps, while the mine is put into shape for exploration and development work. The property is also situated on the government trail which is being built between Ixtlan del Rio and La Yesca, at which latter point the Buena Vista y Anexas Mining Co. has just completed the erection of a 180,000 *pesos* cyanide plant.—— Allan R. Partridge has obtained $200,000 from associates in Shreveport., La., for the operation of mines and smelter in the Huicicila district of Tepic.

Cobalt, Ontario.

Enlargement of the Productive Area.—Finds Beyond Cross Lake.—The Temiskaming Vein.—Rich Ore in the Rochester.—The Nipissing Mine.—Unprospected Territory.—Discovery in the Hudson Bay.—Several Finds in Bucke Township.—New Districts to the North.—Mining Under the Lakes.

For several months it was believed that the rich mines of the Cobalt district would be found to lie within a radius of 2½ miles. Today the extension of the productive area is a prominent feature. The shipping mines are steadily paying dividends. Their development work has proved the persistence of ore to 300 ft., and the returns show that only an infinitesimal portion of the low-grade ore leaves the camp. Thousands of tons of ore that will be treated at a profit are lying on the dump, awaiting the erection of concentrators and a local smelter.

The most important development is south of Cross lake. It is in this direction that the Drummond and Jacob mines and the Lawson vein are situated, but it was long believed that these were near the southern boundary of the productive area. It must be remembered that nowhere in the camp had there been found ore richer in silver than at the Foster and the Jacobs. One 20-ton carload from the Jacobs or Kerr Lake mine, shipped nearly a year ago, netted that company $76,000. The discovery of the Temiskaming vein at the 15-ft. level revealed that a wonderful orebody exists nearly two miles south of the Cross Lake properties. The Temiskaming is located in the Third Concession of Coleman, near Lorraine, and the company is now taking out ore that carries 18,000 oz. silver per ton. The orebody has been proved by driving on the vein for several feet, and a 20-ton car of this ore will be shipped shortly, the value of it being estimated at $150,000. There is no other camp in the world where silver mines ship carloads of ore like this.

At the Rochester, in the same concession and in the lot adjoining the Temiskaming, another marvelously rich orebody has been discovered, and further down on Lots No. 1 and 2, also in the Third Concession, Fred Calverley and Ed. Wettlaufer have made some good finds, which they have been trying to keep quiet.

The Nipissing is a mine that has caused a sensation. The property has been known to be large, but some have sought to create the impression that it was only the ground lying on Cobalt lake that would prove valuable. Of the 850 odd acres only a small portion has been prospected. Take the map of the township of Coleman and you will see that the Nipissing owns part of R.L. 400 or about 100 acres lying north of Cobalt lake and north of the T. & N. O. railway. The other part of R. L. 400 is owned by the Russell, Chambers & Ferland syndicate, which originally owned all of Nipissing. To the west of this 100 acres of the Nipissing and directly adjoining it are the Coniagas, Trethewey, and Hudson Bay properties, each containing 40 acres, the Coniagas being the southerly 40 acres and the Hudson Bay the northerly 40 acres, with the Trethewey in between them. The company designated as the Hudson Bay is really known as the Temiskaming & Hudson Bay Co., and like the Russell, Chambers & Ferland syndicate, got in on the ground floor and staked several acres. The celebrated Silver Queen was part of their original holding.

The splendid discovery made on these 40 acres, owned by the Hudson Bay Co. simply means another bonanza vein for the Nipissing. Last week the Hudson Bay people made known their discovery, which consists of a fissure four or five feet wide that has been uncovered for about 400 ft. It contains from 4 to 12 in. of solid ore, which in places is worn absolutely smooth by glacial action, and the entire width is highly mineralized. This vein runs slightly south of east and has been proved right up to the boundary of the Nipissing, and there is no reason in the world to doubt that it will be just as rich on the Nipissing property, and from there may run to the O'Brien, Chambers & Ferland property, which lies still further east. The important bearing that this discovery will have on the Trethewey is that the workings of this property are entirely at the southerly limit, and this discovery bears out what Frank Loring has claimed, namely, that the 35 or 38 odd acres of the Trethewey that are unprospected, and at present a great big blank, have enormous possibilities.

The owners of properties in Bucke township have been greatly excited over the rich discovery made on the east 20 acres of the northwest quarter of the north half of Lot 13 in the First Concession, formerly owned by McDonald & McMahon, now owned by the North Cobalt Mining Co., of which Dr. Von Hagen is the president. In the bottom of their shaft at the 35-ft. level a rich vein fully three inches wide has been found, a mass of calcite and silver. The wall-rock for a distance of three feet is so heavily shot with leaf silver that it will make high-grade ore. The shaft was started on a small calcite stringer, and is another proof of what the thoughtful men of the camp have been claiming for a long time, namely, that development of this district will prove the existence of an immense number of blind veins, and today no matter how rich the discovery may be, nothing is considered surprising. The new silver camp 50 miles up the Montreal river known as the Elk Lake Extension, the camp in the Temagami Reserve known as the Lady Evelyn, and the gold discoveries around Larder lake, and further north above the height of land at the Mosher Gold Camp, may be regarded as only the beginnings—a suggestion of the mining wealth in the millions of acres still unexplored in this portion of northern New Ontario.

At Cobalt itself the Lake propositions are attracting a great deal of attention, and none more so than the Peterson lake. This property is surrounded almost entirely by the Nipissing and consists of 228 acres of Peterson and Cart lakes, which are now being worked by the Peterson Lake Silver Mining Co. Fifteen veins have been proved to run into this lake from the Nipissing and Nova Scotia properties. The big bonanza vein heads for the lake. A large gang of men were employed last summer and over 170 acres will be worked this summer from the surface. Diamond-drill work is now going on and the drill is working on the lake near the Nipissing, and stripping is being done on the shore to locate this vein. Already fine indications of cobalt bloom and highly mineralized calcite have been found. The rich finds that were made on the Nova Scotia consisted of large slabs of native silver. The vein on which they were found runs right into the lake and these slabs were discovered less than 30 ft. from Peterson lake. No wonder a feeling of great optimism prevails throughout the camp.

Denver, Colorado.

Open Winter. — Scientific Associations. — Zinc Production. — Lake County and Its Varied Yield of Minerals.

Colorado has been rejoicing for the five months past in the most open winter the State has had for years. The temperature has been remarkably high and the quantity of snow that has fallen is unprecedentedly small. If no belated snowstorms come in the spring the prospector may betake himself to the hills much earlier than is usually possible. His prospect hole will be correspondingly dry, for the light snow-fall will operate to lower the amount of ground-water.

In the same way the districts whose water is mostly from the surface may look forward to a summer of light pumping, unless the dry winter is followed by a correspondingly wet summer. But what is one man's meat is another man's poison, and the state of affairs that makes the miner rejoice is bemoaned by the ranchman, who looks forward to a summer of restricted irrigation and small crops.

One of the most valuable privileges that an engineer can possess is the opportunity to mingle with his fellow-workers, and by the friction of mind against mind sharpen his own faculties to a greater keenness. The meetings of the American Institute of Mining Engineers are educational in the best sense. But meetings so infrequent and often at great distances from the mining centres can only partly serve the purpose. They need to be supplemented by local meetings, more frequent, enough so that all may find opportunity to attend a part, at least. This can best be met by the formation of local societies. A good example of such is the Colorado Scientific Society, at Denver, the earnestness and high quality of whose work is evidenced by the publications it has issued in the past. Another is the Pike's Peak Polytechnic Society, at Colorado Springs, which meets twice each month for the discussion of technical subjects, and maintains, in co-operation with Colorado College, a reading room and mining and metallurgical reference library. Smaller communities do well in imitating on a smaller scale as far as their circumstances will permit the work of such organizations, and thereby keep their members in touch with the progress of other workers in the same fields of endeavor.

In the great increase in the importance of zinc, certain Colorado districts find a notable addition to their mineral wealth. In ten years the value of the zinc produced annually in the United States has quadrupled and the quantity produced has more than doubled. This has

chiefly been due to the increase in the consumption of this metal, resulting from the progress of the electrical industry, so that a double production barely suffices for needs that were much more than met by the smaller production of a few years before. Under the stimulus of the increased demand, the metallurgy of zinc has developed, so that its recovery is cheaper and better than at any previous time, and the metal, whose presence in an ore was once deplored, is now welcomed. Colorado ranks high as a producer of zinc, about one-fifth of the total production of the United States being properly credited to this one State. Nearly all this comes from Leadville, Lake county furnishing over 80% of the total. Summit, Pitkin, and Mineral counties are its nearest competitors, each furnishing two or three per cent of the production.

Lake county stands supreme as the chief producer of mineral wealth among the counties of Colorado. In all except gold and coal it holds the first place. Teller county surpasses it in gold, with a production of $14,000,000, against Lake county's one million and San Miguel county's $2,500,000. In most of the other useful metals, it is more than double its nearest competitor, with three millions in silver as against $1,500,000 for Pitkin county, $2,500,000 of lead against less than a million for Pitkin county, $750,000 of copper as compared with less than $500,000 for San Juan county; and more than twenty times as much zinc as Summit county. It well deserves the title of the chief province of a mineral empire.

Johannesburg, Transvaal.

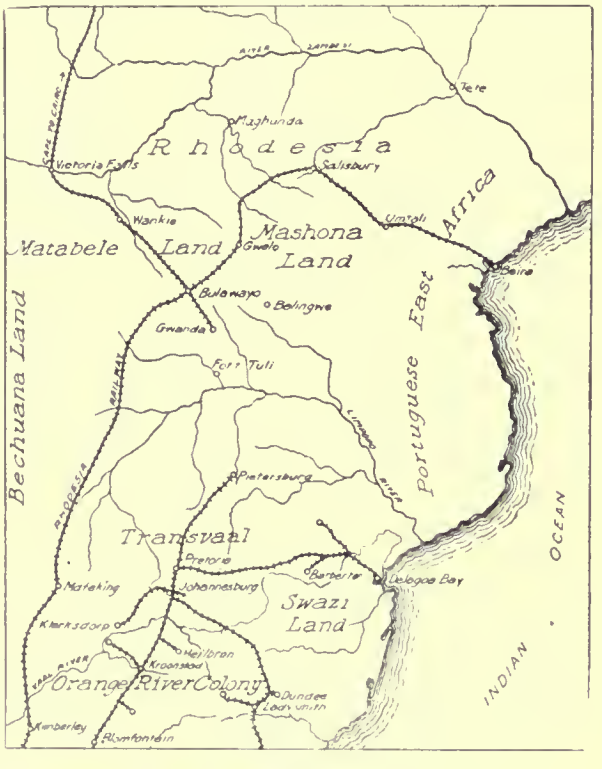
After the Election.—Results Fairly Satisfactory.—British Acceptance of a Boer Administration.—The Problem of the Unemployed.—Chinese New Year.—The Gordon Drill.

The battle is over; the dead and wounded have been buried or amputated, and the field is clear once more. In other words, the election is over. And jolly glad every one is! The campaign was a hard-fought one, and now both victor and vanquished are resting after the fight. Very few available voters were allowed to remain at home. The lethargic ones were pulled out of the mine, or out of bed, and taken to the polls by the enthusiasts of the different parties.

On the whole, the results are fairly satisfactory. The Progressive champion, Sir Percy Fitzpatrick, gained a complete victory over the Nationalist and Het Volk champion in Pretoria, namely Sir Richard Solomon. From the first it was apparent that the Progressives would be utterly routed, but this has proved false, as the Progressives have, on the whole, made a good showing. The Dutch party, Het Volk, will have a majority in the Lower House of 19 or 20, but the Progressive minority is made up of men of such fighting calibre that they will make their influence felt. It is too early yet to say who will be the first Premier under British rule, but now that Sir Richard Solomon is defeated, it is highly probable that General Smuts will be called to this high office. He is an able advocate in Pretoria, whose knowledge of the mining industry is meagre. Only a few years ago he was one of the most successful generals in the field against the British forces. Today or very shortly he will probably be Premier! [General Louis Botha has become Premier, but our correspondent's remarks would apply to him also.—Editor.]

The mines got through election day very well. Almost all the men turned out to work, and were given every opportunity to vote. The artisans went almost solid for the Progressives, only a few Labor members being returned. It will be some time yet before the members of Parliament get to work, and we know their feeling toward the mining industry. Thousands of Chinese contracts will terminate this year, and, if the coolies are sent away, there will be a serious shortage of labor. The general feeling is that there will be something of a compromise on the Chinese question, and that the industry will be allowed to retain about 60,000 coolies. Since the anti-Chinese champion, Mr. Creswell, was defeated by a Progressive, people do not expect any drastic measures.

The problem of the unemployed is still with us. On account of the prosperity now reigning in Australia, an effort is being made to get the stranded Australians now on the Rand back to their country. The unfortunate part of the business is that in six months or so, provided there is favorable legislation, all those now out-of-work will be needed on the Rand. The Government has started relief work, in the form of road building in the Rustenberg district, but it is noticed that there is no rush on the part of the unemployed. As a matter of fact, the question of unemployed is more difficult on the



Map of the African Goldfields.

Rand than in almost any other part of the world, for the white laborer gets very proud out here, and frequently refuses a job if he thinks it is below his dignity.——The Chinese new year festivities went off successfully, and there were no outbreaks or crimes. The coolies took the three days allowed them by law, and during that time most of the mills of the Chinese mines were idle. February will therefore show a decrease in the gold output.

The Lion Hill diamond mine is still a great favorite with the public, the shares having touched £20 several times. One of the big houses has taken up the proposition, so that there will be plenty of capital to prove whether the prospect will turn into a mine.——The annual meeting of the Randfontein Estates was held recently. This is a large group of mines, controlled by J. B. Robinson, on the West Rand. The two most important points raised at the meeting were the scheme for a big electric central power-station. It will be a bit of a blow to the promoters of the Victoria Falls power scheme to know that they will probably lose the custom of Randfontein. The other important point is the high praise given the Gordon stope-drill, which has been designed to replace hammer-men in narrow stopes. If this drill proves the success that some claim for it, the demand for unskilled labor will be greatly reduced.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE cost of refining a ton of crude copper by electrolysis varies greatly, ranging from about $10 up to nearly $25, but the average cost is likely to be about $11.50 to $13.50.

A RESIDUAL CLAY derived from a rock composed entirely of feldspar, or one containing little or no iron oxide, is usually white and therefore termed a 'kaolin.' Deposits of this type may contain a high percentage of the mineral kaolinite.

A STUDY of economic geology shows that the deposits of both lead and zinc ore, whether in association or alone, form most readily in connection with a dolomite or limestone country. Most of the great lead and zinc ore deposits of the world occur in formations of those rocks.

THE La Salle St. tunnel under the Chicago river is having its crown removed, and as the originally proposed new roof has not been built, this tunnel is now practically destroyed and abandoned. A steam drilling scow, such as is used in harbor improvement work, was employed to drill holes in the roof for blasting, and the site was dredged by a large dipper dredge.

THE stamps of Gilpin county, Colorado, drop about 30 times per minute, while the average on the Mother Lode of California is about 90, with a maximum of about 105. In Colorado the stamp weighs from 500 to 600 lb., while in California 850 lb. is the average, with 1,100 lb. as a maximum. In Colorado, the drop ranges from 16 to 20 in., in California, from four to six inches.

THE life of a mortar-screen depends upon the hardness of the ore, the acidity of the battery water, the attention given to them, etc., but it is chiefly regulated by the length of time which the superintendent considers it desirable to retain them in service. A screen will often last without breaking for 20 days or more, but its openings become so enlarged by abrasion that a much coarser product escapes from the mortar.

UNDER processes recently patented an improvement in the manufacture of stone-like substances has been achieved. The inventor has succeeded in what is little short of a reconstruction of many well-known qualities of building stone. By a slight modification, all kinds of marble are produced, and one of the chief successes has been in the manfacture of lithographic stone, which has been pronounced by experts to surpass the natural material.

OVER 500,000,000 gal. of water are pumped out of the anthracite coal mines of Pennsylvania every day in the year. The exact average for 1905 was 633,000,000 gal. per day. Nearly 1,000 powerful engines, delivering from mine bottom to surface 500,000 gal. of water per minute, are required. Mines may be shut down and coal production suspended, but the water flows on forever. The cost of removing it is one of the important items of expense that make up the price of anthracite.

IN THE mortar of the stamp-mill, the irregular splash of the water causes an unequal sizing of the pulp, as the particles of pulverized material may pass through the screen or be retained in the mortar, depending upon whether any particle is thrown against an opening or a blank in the screen. If a particle does not pass through, it is drawn back by water and undergoes further reduction in size. This action takes place to a greater extent in a deep mortar with a punched screen, than in a shallow mortar with a wire screen.

THE Land Department has held that the pendency of an adverse suit excuses for the time being the performance of annual labor. The Courts have not as yet passed upon the question. The ruling of the Land Department may be upheld as between the litigation parties, but there might be danger from re-location by outside parties disconnected with the litigation. It would be prudent to perform the work, or at least make a *bona fide* attempt to perform it. If the attempt is frustrated by acts, or threatened acts, of violence, performance would be excused. [This appeared in our issue of January 7, and is repeated now in consequence of further queries covering the same ground.—Editor.]

EXPOSURE to high pressures of oxygen produces convulsions in most animals when in the compressed-air chamber, and these may continue after rapid decompression. Convulsions are not so likely to be produced in animals after rapid decompression from compressed atmospheric air, but the respiration may become embarrassed, and there may be paralysis or death. With compressed atmospheric air it was found that convulsions did not occur until 12 atmospheres were reached, owing to intoxication from the oxygen being too gradual. The convulsions end in paralysis, but after rapid decompression from oxygen the convulsions still continue because the oxygen set free can maintain the life of the tissues. In decompression of atmospheric air it is nitrogen that is set free.

PROFESSOR MOISSAN, in vaporizing gold in the electric furnace, finds that 100 to 150 gr. can be evaporated in two or three minutes. By condensing the gold vapor on a cool surface, either filiform masses or cubical crystals can be obtained. It is found that gold, like copper and iron, dissolves a certain amount of carbon when in the liquid state, but this separates out as graphite on cooling. Gold is to be found less volatile than copper. The properties of distilled gold are the same as those of hammered gold, or the melted metal reduced to a fine powder. When an alloy of copper and gold is distilled, the vapor of copper comes over first, showing that there is no definite compound. In the case of alloys of gold and tin, the latter metal burns in contact with air. This tin oxide is found to be of a purple color, due to a deposit of fine gold on its surface.

THE strongest brick ever tested at the Watertown Arsenal was a paving brick from St. Louis, Mo., which showed a compressive strength of 38,446 lb. per sq. in., with a modulus of elasticity of 8,510,000. The absorption was 0.21% by weight and 0.5% by volume. The sample tested was set on end and measured 2.45 by 3.09 in. in cross-section. Granite of 51,990 lb. per. sq. in. compressive strength came from a quarry in Asheville, N. C. Ordinary granites range from 20,000 to 30,000 lb. per sq. in. Cement-rock is the stone from which natural cement is made in the State of New York. A brick of 38,446-lb. strength was tested. Ordinary values for hard-burned brick range from 12,000 to 25,000 lb. per sq. in. Portland cement, set under pressure, attained the maximum strength yet observed in this material. This sample was exposed to an initial pressure of 14,000 lb. per sq. in. while setting. The strength given was displayed by the cement at the age of 57 days. The compressed strength of ordinary portland cement, tested neat, ranges from 6,000 to 9,260 lb. per square inch.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Pans vs. Tube-Mills.

The Editor:

Sir — With reference to the discussions that have appeared in the MINING AND SCIENTIFIC PRESS regarding the relative merits of pans and tube-mills as sliming machines, it may be of interest to publish the results of some tests carried out at the Dolores mill, in Chihuahua, Mexico.

In test No. 1, the ore was crushed with cyanide solution by 15 stamps, weighing 900 lb., through a 2-mesh screen, the pulp passing to the two Bryan mills with 60-mesh screens, then to four pans in series, thence through two settlers, and finally through two cone-classifiers. The overflow from the classifiers went to the agitation plant, and the underflow was returned to the tube-mill for re-grinding, the re-ground product joining the stream from the settlers at the head of the cones.

In test No. 2, the pulp from the Bryans passed directly to the tube-mill, thence to the cones, the overflow as before to the agitation plant, the underflow being returned to the head of the pan series, thence through settlers to cones as before.

In both tests samples were taken every hour, over periods of twelve hours, from the heads of the tube-mill and heads of pans, and also from the discharge of same. The bulk 12-hour sample was determined from the proportion of sand and slime in each sample, the difference in slime content between heading and tailing being taken as the sliming power of each machine.

The following are the results obtained, from the average of five samples:

TEST NO. 1.

	Percentage of slime.		Percentage of slime.
Tube-mill heading	8.20	Pan heading	11.02
" " tailing	42.64	" tailing	52.54
Slimed by tube-mill	34.44	By pans	41.52

TEST NO. 2.

	Percentage of slime.		Percentage of slime.
Tube-mill heading	4.66	Pan heading	7.36
" " tailing	44.08	" tailing	51.88
Slimed by tube-mill	39.42	By pans	44.52

Taking an average of both tests, to bring the machines under the same conditions, gives the following result:

Percentage slimed by tube-mill	36.93
" " " pans	43.02
" In favor of pans	6 09

The pans used are of the Wheeler type, with plain flat muller and dies; they have a diameter of five feet. The speed is 65 rev. per min. The power required to drive the four pans is 50 h.p. The tube-mill is a machine specially constructed by Allis-Chalmers, made in sections for mule transport, and I believe is one of the first, if not the first sectional tube-mill made. It has a length inside of 16½ ft. by 3 ft. 6 in. diam., and runs at a speed of 35 revolutions. It is lined with white iron, and carries a load of 4½ tons of flint pebbles. The power required to drive it is 20 horse-power.

Although the above tests showed a small margin in favor of the pans for sliming, yet when the question of power and cost are considered the tube-mill is undoubtedly the more economical machine. The wear and tear in the case of the pans is considerably more than that of the tube-mill, and the difference in power required for driving, by itself would more than minimize any advantage the pans have in sliming capacity.

ROBERT CLARKE.

Dolores, February 17.

Those Bob-Tailed Words.

The Editor:

Sir — I wish to enter a word of protest against what seems to be a prevailing use by a few of the leading mining journals of singular nouns for plural — shaving, tailing, *et cetera*.

The leavings after quartz is crushed and the free gold removed are tailings. One could not correctly say dregs are tailing, dregs are tailings. The man who doesn't believe there is plurality to the product of a stamp-mill should be given the task of counting the particles in a few tons. According to the new fashion I would have to write this "particle in a few ton," but it so happens there are particles and tons.

I well remember that when I stood before my own zinc lathe it wasn't a shaving I made, but shavings, and lots of them. I recognize that now, when most of this work is done by machinery, a shaving may be a mile or more in length. We may break this shaving and put part of it in one compartment of a zinc-box and part in another. Thus, it seems to me, we have shavings, and it would be hard to find an extractor that didn't have more than one shaving in each compartment.

Please stock up on the s box, and don't let the printer get out of 'sorts' again. It jars an intelligent reader to have such obvious misuse of words.

MATT. W. ALDERSON.

Helena, Montana, March 18.

[We disagree with Mr. Alderson, as our readers will be aware. But we take pleasure in publishing the expression of views contrary to our own. Open discussion is valuable.—Editor.]

Black Sands.

The Editor:

Sir—Your timely editorial on 'Black Sands Again' is to the point and greatly appreciated. Field experience of the writer corroborates the statements made. Dr. Day's investigations have been of little practical benefit, and have caused useless expenditure of time, energy, and money by investors that were led to believe that a new source of mineral wealth had been discovered by the learned member of the Geological Survey. The promoters made much capital of the experiments at the Portland Exposition, as it was only necessary to send samples of their own taking, and receive in effect an endorsement as to the value of their property. This class of people had never before appreciated so thoroughly the work of the Survey.

The difficulty with the whole matter, from an engineering standpoint, is that there is no known body of black sand of sufficient size and value to warrant consideration.

Experience on one examination may be taken as typical. The promoter, after discoursing at great length in glittering generalities on the merits of the property, when requested to designate some place where values could be found, led the way to a favored spot, where scratching at the roots of a tree he produced some handfuls of debris, which, when panned, showed a few minute scales of platinum. I say "favored spot," because two other engineers, as I afterward ascertained, were taken to the same place. No values were found elsewhere on the property, except at a few spots, the result of local concentration.

Investors to whom 'black sands' still appeal would do

well to demand a guarantee sufficient to cover expenses before causing an examination to be made.

CHARLES JANIN.

Oakland, California, March 30.

The Butters Filter.

The Editor:

Sir—So much has recently been written about the respective merits of the Butters and other filters and so few actual data have been given that I thought it would interest the mining public to get the working costs, as well as the metallurgical results achieved by the Butters filter during the period of continuous running.

The article by Mr. F. L. Bosqui, in your issue of February 2, covers the ground so well from my point of view that I shall simply endorse it as written and make no further comment. I would point out that my figures relate to one year's continuous running and that the filter in question has been steadily working for more than eighteen months. Nevertheless, it is in as good condition today as when it was first erected.

The high cost of freighting between the Coast and Copala tends to increase the cost of maintenance. The following is the summary:

FOR YEAR ENDING JANUARY 31, 1907.

Total tonnage filtered	24,066 tons
Average filter-residues during year	Gold 9 cents, silver 0.98 oz.
Average charge per filter of 94 leaves	20.02 tons
Number of charges	1,202
Average time of operating one charge	1 hr. 36 min.

COST OF MAINTENANCE.

Acid (HCl) for washing filter-leaves one year	$1,596.00
Repairs to filter	2.69
Repairs to 4-in. centrifugal pumps	49.60
Repairs to vacuum-pump	3.50
Total	$1,651.79

COST OF POWER.

Vacuum-pump (4 h.p.) 1,622 hr., at 17 cents per hr	$ 110.29
Centrifugal pump for elevating excess pulp and solutions, 8 h.p., 801 hr.	108.93
Centrifugal pump for elevating the filtrate, 8 h.p., 365 hr.	49.64
Excess slime agitator, 2.5 h.p., 550 hr.	23.37
Total	$ 292.23

COST OF LABOR.

One man at $45 per month, one year	$ 540.00
One boy at $12 " " " "	144.00
Extra help, washing frames, etc.	32.00
Total	$ 716.00

Yearly cost of maintenance	$1,651.79
" " " power	292.23
" " " labor	716.00
Total yearly cost	$2,660.02
Cost per ton of slime	$0.1105

The capacity of the filter is 200 tons per day, but it has never been taxed to even 50% of its capabity; in fact, the unit-charge is now 26.5 tons and the results are quite as good as with the smaller tonnage.

In conclusion, I would say that we have gone on record with a complete sheet of operations and it would be interesting to see similar data published from the other filters on the market. Mr. Bosqui's suggestion is a practical one.

JAMES FRIER,

Manager for the Butters Copala Mines Co.

Copala, Mexico, March 5.

The Meaning of Striations.

The Editor:

Sir—I have seen somewhere that if a vein is enriched as the result of a fault, the enrichment would take place along the upper side of the fault. Is there any such law, and if so, which is the 'upper side' of the fault?

I also understand that the striations on the walls of a vein, due to movement, bear some relation to the position of the ore in the vein. Is there anything in this theory? A vein that I have been endeavoring to open up is cut by a dike. The striations 500 ft. from the dike are almost horizontal, but dipping slightly toward the dike, while the striations about 30 ft. from the dike dip at an angle of about 30° from the vertical, also in the direction of the dike. The best ore that I have found in the vein occurs at this point, but the vein does not average well. Do these striations argue for better bodies of ore below, or are they simply the evidence of movements having taken place in the vein independent of any economic value?

At the opening about 30 ft. from the dike, although the vein might be said to be quartz, a stringer of crystalline calcite about four inches thick occurs near the centre of the vein, giving it a banded appearance. This calcite carries no mineral, but the adjacent quartz does. The country traversed by the vein is diorite, and there is no lime within a mile of it. Is this a favorable indication? The ore is a gold-bearing chalcopyrite.

HORACE W. BUCKE.

Ketchikan, February 28.

[In regard to the effect of a fault, the enrichment will depend upon the direction of flow of the mineral solutions that followed the line of the fault; if from below, the upper part of the faulted vein will be benefited; if from above, then that part of the vein below the intersection. A fault that enriches another vein is really a beneficiating cross-vein. At Rico, Colorado, these relations are well emphasized. Speaking generally, down to the ground-water level, the solutions producing enrichment are likely to have been from above; if such an effect is observed below the level of ground-water, it is likely to be due to ascending solutions.

Yes, striations are regarded as indicating the direction of movement in fault-veins, and there is reason to believe that such movement has influenced the pitch of ore-shoots, by creating a well-defined width of crushed rock or band of shattered material easily penetrated by enriching mineral solutions.

In regard to the calcite, it is a fact that in the celebrated Cobalt district, the rich ore accompanies calcite, the presence of which marks the line of passage of the ore-forming waters that made the bonanzas of silver mineral. At the Palmilla mine, in Chihuahua, Mexico, there is a big vein of calcite near the place where large orebodies are found. It is likely that this calcite, while itself uot valuable, marks the occurrence of a period of secondary ore concentration. We shall be glad to see the matter discussed by some of our geologists.—Editor.]

MICA is only of value when found in considerable quantities and in the form of large sheets. Small quantities of this mineral have come from South Dakota and Wyoming, but most of our domestic mica comes from New Hampshire. The finest and cheapest mica we have is imported from India, while Canada produces a good deal of non-transparent mica. The whole United States only produces about $100,000 worth of mica per year, of which New Hampshire produces about $70,000 and North Carolina $25,000, leaving only about $5,000 for other States.

STALACTITES are formed by waters containing limestone in solution percolating through the roofs of limestone caverns. Some stalactites are of enormous weight and several yards in length, having taken form from the gradual drip of water from above, and to obtain a growth six feet long and a weight of 500 lb. has taken hundreds of years, the infinitesimal quantity of lime in each drop of water producing a splendid structure in the course of ages.

Old Mexican Workings and Some Remarks on Sampling.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

At the Peregrina mine, near Guanajuato, I had a good opportunity of examining some typical old Spanish-Mexican workings. We entered by a door into a small gallery and thence through the opening or mouth of the mine (*boca de mina*) that descended into the darkness. The way was down a twisting stairway that zig-zagged within the vein-walls; the steps were laid in lime mortar, the general slope varying between 45 and 56°. Such passages are common in the old Mexican mines; they are made in stopes, the filling of which has been used to build the masonry of the stairway. At intervals shrines are to be seen; there was one 30 ft. from the entrance, just at the end of daylight, and there was a principal shrine in a parapet above the big workings (*obra grande*) at the 100-ft. level. Every shrine is guarded by lighted candles, left there by the miners; and it is said that they will even go up and down the underground passages in the dark in order to save candles for this purpose. At about 5 o'clock, when the shifts change, there are 150 to 200 candles burning before the principal shrine, forming a grand illumination, the effect of which is heightened by the cavernous old stopes that yawn in front of the sacred image. As they pass it, the men stop and make a genuflection, with the sign of the cross. Descending further, the stairway becomes wider as it passes into the big stope and we noticed another shrine—a cross set in a frame, with a solitary candle; this marks the spot where a man carrying drills (*refaccionero*) tripped at the head of a series of steps and fell fatally.

Flash-Light Photograph of a Big Stope in the Peregrina Mine.

The big stope is a cavernous excavation 250 ft. long, by 450 ft. deep, and 8 to 25 ft. wide. The footway at the end of the first stairs, about 100 ft. from daylight, is blasted in the wall of the lode and is provided with a parapet of masonry. Leaning over it, one looks into an abyss, the effect being like a miniature Cornice road underground. The lode is nearly vertical, changing from 80° W at the south end of the mine, to a dip of 70° E at the north end. The ore is from 8 to 20 ft. wide; it consists of quartz, partially ribboned and traversing a breccia, the edges of which show replacement; it follows a line of fracture in the breccia; where the vein is tight and the quartz massive, the silver is highest in proportion to gold, ranging from 50 to 55%. Going south the lode becomes more open, the vugs contain clay, and there is such evidence of leaching as is usually seen close to the surface. In this part of the mine the proportion of silver to gold is smaller. The Mexicans could not work the gold ore because the *haciendas* paid nothing for gold and the ore-buyers gave only 30 *centavos* per gram, when it is really worth 66 cents or about 140 *centavos* per gram. This ore cannot be sorted like that which is rich in silver, the argentite being visible in threads and spots, while the metallic gold is disseminated in particles too small to be seen. The argentite sometimes impregnates the calcedonic quartz so delicately as to make a moss agate.

Our progress through the mine was lighted by two *peones* who carried *mechas* or torches. Mr. E. P. Ryan, the superintendent of the property, carried an acetylene lamp, so that the old and the new were well contrasted. The time may come when acetylene will be in general use underground, but it will not become popular until the present lamp is superseded by something better. As it is now, you have a small can that holds the granulated calcium carbide and to this water is added; then the cover is securely replaced and the chemical action produces the acetylene gas, which is lit as it escapes through a small aperture. The smell of it gave me a headache, both in Mexico and in the Lake Superior copper mines, the two districts where I used acetylene lamps. But there is a newer invention that promises to prevent the escape of gas and the consequent headache. The emission of gas is nicely regulated and all of it is burnt in the process of illumination.

We met boys (*tanateros*) carrying waste in *tanates*, the bags made of the fibre taken from the *ixtli*, a variety of *maguey*. We were passed by others who were descending to the place of their work, whistling as they went at a trot down the rough steps. Then, in contrast to such breathing antiquities, we found a couple of young min-

ing engineers* who were taking samples in a thoroughly modern way, aided by Mexican miners to do the moiling. The quartz ore was hard and 10 to 15 ft. wide, so that two moils were blunted per foot of sampling. They used the straw hats of the *barreteros* to catch the sample. As we proceeded, I could see by the white channeling across the dark drifts that the sampling was being well done.

Speaking of sampling, reminds me of the old dumps and the way they were tested. At the Peregrina, this work was done by George A. Schroter. He did it with system and care. An aggregate of 250 ft. of shaft-sinking was required; one shaft was as much as 70 ft. deep, the usual depth being 40 ft. Each shaft was 3 by 4 ft. in the clear; it was kept open by small timbers of 4 by 6 in. cross-section. Two-inch round oak spiling was driven over a 'bridge' by double-hand hammers, as fast as the ground yielded, in consequence of the removal of the material at the bottom. The hoisting was done in baskets. The average cost was $1.25 for the first metre and then 25 cents extra for each succeeding metre of sinking. The material obtained from each metre of shaft was kept separate and sorted, for 25 *centavos* per ton. This sorting was done by women, who made three piles, consisting respectively of fine ore, lump quartz, and waste. On the day of my visit there were 60 to 70 women at work, handling 100 to 110 tons per day. They are better than men—more steady, because they do not stop to smoke a cigarette; nor do they steal as much as their husbands and brothers. The sorting is done with a 3-lb. hammer, a horn spoon, and wicker basket (*chiquihuite*) reinforced with hide, holding about 30 lb. of ore. The dump contained $8 to $9 per ton, 70% of this assay-value being in gold. In the open-cut, where the ore is mixed with wall-rock, the assays averaged about $4.50 per ton. Underground, it was found that the filling of old stopes ranged between $5 and $10, being highest in the southern part of the mine, where the ore is more difficult to sort.

The dumps of Guanajuato have figured largely in recent prospectuses, many companies having been organized with the particular purpose of treating the ore left by the old Mexican managements. On careful inquiry, I can give the average assay-value of the best of these immense accumulations as 4 to 6 oz. silver, and 1.5 gr. gold per ton, equivalent to, say, $4 per ton.

When the American invasion began, the Mexican was not slow to appreciate his opportunity. In one case, *peones* were set to work removing the dump in sacks and loading *burros* with it, so as to impress a visitor with the idea that the stuff was fairly rich. But grab samples gave 5 oz. silver per ton. It was hardly worth sacking!

As regards sampling, in our conversations emphasis was laid upon the danger of doing the work without trustworthy assistance. When using outside help, it is difficult to prevent salting, if well planned, unless the following three operations be performed:

1. Take samples with the help of the miners available.
2. Blast the lode at a few points and take check samples.
3. Cut down another set of samples yourself, with the aid of the one personal assistant, without which such work should not be undertaken.

Mexican miners make poor assistants to an engineer sampling a mine. When the groove is being cut across the vein, they linger in the rich ore from force of habit; it is hard to make them understand that the poor quartz must be included. To this very day, the Mexicans at Guanajuato deride American engineers' method of sampling. One of our friends had taken a large sample laboriously and carefully; he was just in time to see the foreman of the mine in the act of throwing out pieces of poor rock. "*Tiene nada*," it carries nothing, he explained, as though it were foolish to include anything but rich ore. Other engineers can tell you of similar experiences, when after breaking a sample with infinite care to make it a true section of the vein, their Mexican helper has picked out the barren-looking quartz. The whole training of the native for generations has been to sort his ore, rejecting the poor stuff, and he cannot get it into his head that anyone should do otherwise. But he is not the only eccentric; I remember that more than once in Western Australia owners of mining claims, or their representatives, wondered why I did not sample the small patches of specimen ore. One incident I shall not forget, for I have a memento of it. Having been retained to inspect a mine at Red Hill, near Coolgardie, I was escorted to the spot—50 miles away—by a Mr. Patrick Walsh, a local celebrity of the boom days. His language was picturesque and free, he had rudimentary ideas of mining, and he took me for a tenderfoot—they call them 'new chums' in Australia. The mine had several shafts and a couple of shallow adits, most of which had but little ore to show, but on the top of a small ridge there was a trench that exposed a quartz cropping in which glistened a patch of beautiful specimen of gold ore—ounces to the pound. I admired it and proceeded to pass on, but he asked me if I did not intend to take a sample, for in those days pseudo-experts took a dozen samples of poor quartz, and then a thirteenth unlucky one of specimen stuff, and averaged the lot, with the result that 4 dwt. ore appeared in their report as running 2 oz. 10 dwt., or something like it. Seeing that Mr. Walsh would think I was not fair to his mine if I demurred, the sample was taken. But it was never assayed; the gold was melted, and I now possess a pair of handsome cuff buttons to remind me of Red Hill, Western Australia.

To return to Guanajuato; sampling of the streaky lodes in that district is difficult; re-sampling of the same groove is known to have given three such divergent results as 1,800, 350, and 150 grams of silver per ton. The discrepancy is due in part to the fact that the threads of argentite are thin and wavy in direction, so that when the groove is made deeper by a later cut, the amount of silver mineral obtained is less or more, according to the chances of striking or missing a streak or *hilo* of argentite. Re-sampling is usually accompanied, in the case of an intelligent engineer, by the special desire to avoid taking too much of the rich stuff, and this is apt to cause a leaning the contrary way. On the other hand, the first sampling—made for the vendor—is apt to be left to the Mexicans, who instinctively put too much of the soft argentite into the hat that holds the ore as it is broken.

The story is told of a mine that, along its main level, showed a width of 8 to 10 ft. of beautiful quartz ribboned with black threads of rich mineral. The back of the drift looked handsome. An option was secured by Americans residing at Guanajuato, who knew rich ore when they saw it. The sampling done by an engineer in behalf of a putative purchaser gave the astonishingly low results of an average of $2 per ton. A protest against this finding ended in the breaking of a few tons of ore with a view to checking the sampling, and the result was 5 cents per ton less. The black streaks were stibnite!

There was another story of an ore-purchasing agent who found that the smelter returns at Monterey were 30% less than his own sampling, on which he had made settlements with the Mexicans. He discovered that the ore, when being sampled at the mine, was turned over in

*G. A. Kennedy, of the Colorado School of Mines, and L. C. Pearce, of the Michigan College of Mines.

the teeth of a wind that blew the fine black (silver) dust over the fraction representing the pulp that went to the assayer. This residual portion was always placed to leeward. He lost 8,000 *pesos*, but took his medicine like a sportsman. In the course of time, it was decided to sample at the receiving station instead of at the mine; there was a nice yard (*patio*) available for the purpose, it was paved with red brick of the usual soft character. The *buscones* (tributers, or lessees of the mine) sent a representative to watch the sampling in their interest, and he noticed that the sweeping of the floor threw red brick-dust into the sample. He became fussy, and insisted that the objectionable material should be ejected, and it was. The ore-buyers' agent did not prove obdurate, for the brick-dust included fine particles of rich ore that filtered to the bottom, making a mixture 15% richer than the average. The 8,000 *pesos* that had been lost were soon recovered, and a few more to make them comfortable.

The buying used to be done entirely at sight, the grade and weight were both guessed — with plentiful allowance for error and deception. The *buscon* would make a pile and put big chunks of good ore on the outside, and then fill his mouth with water and squirt it over the pile, so as to make a fine showing of black (silver) streaks across the gray rock, on the same principle as the old woman who polished the apples for sale on her stall.

To change the subject, let me tell the story of a strike. Order is not difficult to maintain at a mining town like Guanajuato, because the people possess a lively respect for the representatives of the law. The strike at the Peregrina mine affords an example. In that episode there figured 500 *peones;* there came four undersized soldiers and a most unimpressive *jefe politico*, or sheriff. The *patio* was full of the striking miners, ready for a riot. The little *jefe* told the manager to open the *patio;* the big doors swung aside; the four soldiers entered with their muskets clubbed and the *jefe* behind them with a drawn sword. The laborers scattered like rabbits, the four soldiers whacked all within their reach, the *peones* fled and fell over the dump; the strike was over!

The introduction of electric power has been of great help in the re-opening of the old mines at Guanajuato. It used to cost 400 *pesos* per horse-power per annum, burning oak fuel and using compound engines. Now the rate is five *pesos* per horse-power month for the right to use electricity, and 0.026 *centavos* per kilowatt-hour, the latter being equal to about five *pesos* more per month if running steadily, making the cost 10 *pesos* per h.p. month. The power comes from the falls of Zamora, on the Duero river, in the State of Michoacan and 101 miles from Guanajuato. There 45,000 to 60,000 volts is generated, with a step-down to 15,000 volts and again to 440 volts. Four thousand horse-power is generated and another plant of equal capacity is in hand. (This must now be completed, for I speak of more than a year ago, when I visited Guanajuato.) The natives were troublesome at first; they cut and stole several hundred metres of copper wire. Two men were killed by a live wire, after public warning of the danger. There was also some difficulty at first in transmitting power, by reason of the sudden change in temperature at dawn, where there is a rise of 15° C. This causes condensation of moisture on the porcelain insulators, which remain cool after the temperature of the surrounding air has risen. The moisture on the insulators is sufficient to cause the current to short-circuit between the iron pin of the insulator and the cross-arm of the iron tower. This happens between 5 and 6 A. M. The only way to stop it is to turn off the current, so that there is a break for an hour. However, energetic investigation into the subject will solve this difficulty, a return to wooden pins being possible. At first the break in transmission was attributed to the malice of discharged employees and then to the eagles, many of which were found dead at the base of the towers. They alight on the top of the iron towers at dawn and stretch their wings so as to arc across the wires, being killed instantly but establishing a short-circuit through themselves before they drop.

Sorting Ore at the Peregrina Mine.

THE touchstone of the jeweler is a jasper of a velvety black color.

The Geology of Goldfield, Nevada.

By FREDERICK LESLIE RANSOME.

*Goldfield is situated on the southern rim of one of the typical desert basins of the region, which merges through a low pass 22 miles north of town into the still larger basin west of Tonopah. A large part of the district may be described as a rolling plateau ranging from 5,700 to 5,800 ft. in general elevation and surmounted by many irregularly distributed peaks and knobs. None of these hills is a volcanic crater, as has been asserted in some descriptions of the district, nor are they due to local volcanic upheaval. They owe their height above the surrounding country merely to the fact that they are composed of material somewhat harder or more durable than the average rock of the region and have thus succumbed more slowly to the general erosion that has carved the existing relief from a gently domed volcanic series. The superior resistance of the hills is in some cases due to the original character of the rock of which they are composed; in other cases to a capping of young and fresh lava, but by far the greater number of the smaller knobs that stud the district, of which Black Butte is an excellent example, are prominent because the rock has been hardened by local silicification in a manner that will be described in connection with the ore deposits.

The fact that much of the district is a rolling plain diversified by rocky knobs has an important bearing in a region where detritus tends to accumulate on all but the steepest slopes. In the Tonopah district, and especially in the Bullfrog district, there is generally a fairly definite line between steep, bare, rocky hills and the gentle alluvial slopes at their base. At Goldfield, however, the general gradients are so slight that detritus accumulates over much of the surface and interferes seriously with attempts to determine the distribution and structure of the underlying rocks.

The geological structure of Goldfield compared with that of most districts in which deposits of the precious metals are found is simple. The district is essentially a low, domical uplift of Tertiary lavas and tuffs resting upon a foundation of ancient granitic and metamorphic rocks. The erosion of this flat dome has exposed the pre-Tertiary rocks at a number of places in the central part of the district, and these outcrops are surrounded by wide concentric zones of successively younger formations. But while it is not difficult to recognize the broad bare outlines of the structure, this general idea requires modification in many particulars before it can be accepted as a satisfactory conception of the geology of the region, and it is in the study of these essential details rather than in complexity of the structure that the investigation of the district offers real difficulties. One of these obstacles, the extensive cloaking of the surface by gravelly alluvium or 'wash,' has already been referred to. Owing to the prevalence of this material the contacts between the various underlying rocks are seldom well exposed and are usually completely covered. While it would be a simple matter to map this detritus wherever it is thick enough to conceal the rock beneath it, the map thus made would be less useful to the miner than one in which an attempt has been made to show the distribution of the possibly ore-bearing rocks, observed facts being supplemented wherever necessary by inferences based upon all available data. In accordance with this general principle the areas of alluvium have been entirely omitted from the preliminary map and will be reduced to a minimum in the complete and final map. That some adjustment of geological boundaries will be demanded when mining operations determine the positions of contacts now concealed is, of course, to be expected; but it is deemed more important to present a helpful interpretation of hidden structure than to be content merely with cautious and unsuggestive adherence to visible facts.

Another obstacle to accurate and successful study of the region is the intensity, widespread distribution, and erratic character of the alteration that has affected rocks, some of which, even in a fresh state, could be distinguished from one another only by refined petrographic methods.

The oldest rocks exposed in the district are found on Columbia and Vindicator mountains, and are particularly noticeable on the southern slope of the former peak as conspicuous dark patches visible from Columbia or Goldfield. Originally thin-bedded limestones or calcareous shales, with subordinate beds of sandstone, the formation is now much contorted and metamorphosed. The calcareous beds have been changed to compact aggregates of quartz (jasperoid) crowded with microscopic black particles, probably carbonaceous, and the sandstone to hard, vitreous quartzite.

The metamorphism is apparently due to the intrusion of these sediments by masses of granitic rock composed essentially of quartz and orthoclase, a type for which Mr. Spurr has proposed the name alaskite. This rock is well exposed on Columbia Mtn. and makes up a large part of Vindicator Mtn. Smaller areas occur in the vicinity of Banner Mtn. Most of the alaskite contains a very little black mica and some paglioclase. In most exposures the mica is decomposed and scarcely noticeable, but northeast of the summit of Vindicator Mtn. the alaskite mass grades into a biotite granite.

The age of the alaskite and intruded sediments, beyond the fact that both are pre-Tertiary, can not be determined from any evidence available in the Goldfield district. Mr. Spurr, whose wide experience in southern Nevada renders his opinion of special weight, considers that the metamorphic sediments may well be Paleozoic and that the alaskite was intruded in post-Jurassic time. S. H. Ball, who recently made a reconnaisance over a large area around the Goldfield district, found Cambrian fossils in beds which he is inclined to correlate with those exposed in Columbia and Vindicator mountains.

It is certain that the intrusion of the alaskite was followed by a long interval during which the region was eroded to the surface of moderate relief subsequently covered by the irruption of Tertiary lavas.

The sequence of Tertiary eruptions as shown by the rocks of the Goldfield district was as follows, the oldest rock being at the bottom of the column:

Olivine basalt; flow and small intrusive bodies.
Breccia and conglomerate.
Rhyolite; flow.
Lake beds.
Quartz-bearing basalt; flow intercalated in lake sediments.
Lake beds.
Latite and rhyolite; flows.
Dacite; sheet-like and irregular intrusions, possibly in part a flow.
Andesite; flows with some tuff and small intrusive bodies.
Rhyolite; intrusive masses.
Rhyolite; flows and tuffs.
Andesite; flow.

The older or first andesite, as may be seen from the map, occupies an area a little over two miles in diameter in the centre of the district, and a small area south of Columbia. Its characteristic features may be well seen in the vicinity of McLaughlan's well, on Banner Mtn., and on the southern edge of the town of Columbia. This rock has not been found in a fresh condition. Its color is usually dull purplish or greenish-gray. A spotted or mottled appearance, due to flow-brecciation, is rather characteristic and is well shown on a small hill half a mile north of the summit of Banner Mtn. The freshest obtainable specimens of the first andesite show pheno-

PRELIMINARY GEOLOGIC MAP OF THE GOLDFIELD DISTRICT.

crysts of feldspar, hornblende, and mica in a compact, streaky groundmass that was evidently once a glass with well-marked flowage lines. All the phenocrysts have the dullness that indicates more or less thorough alteration and the original glassy base is now devitrified. As a rule, the first andesite, when it has not been subjected to the intense local alteration connected with ore deposition, may be distinguished from the later andesitic rocks by the absence of fresh phenocrysts and the peculiar streakiness of its groundmass, which resembles the groundmass of a rhyolite rather than that of most andesites.

The rock is apparently a flow resting upon a clean and rather uneven surface of alaskite and Paleozoic sediments. Its thickness is not known, but it is probably very variable, as on Columbia Mtn. the succeeding rhyolite rests directly upon the alaskite. The maximum thickness is tentatively estimated as at least 400 ft., and it may be considerably more.

Overlying the first andesite, or resting on the pre-Tertiary rocks where the andesite is absent, is a series of thin, glassy, rhyolite flows which is best developed in the rounded white hills northwest of Columbia Mtn. This rhyolite is associated with pale greenish tuffs of mingled andesitic and rhyolitic character and is cut by masses of intrusive rhyolite. All these rocks are shown together, although they will be distinguished on the final map. The effusive rhyolite is usually nearly white, shows conspicuous flow lamination, and weathers in thin, shelly flakes. This is the rock of the Sandstorm mine and of the hills lying west of the road from the mine to Columbia. It all shows some devitrification and silicification, particularly in the vicinity of the ore deposits. Certain varieties or portions of this rhyolite acquired by flowage a very thin lamination, causing the rock when somewhat weathered to closely resemble indurated clay shale. This appearance is very deceptive, as may be seen at the Tonopah Club or Conqueror mine. The town of Diamondfield is partly underlaid by this shale-like rhyolite, and small residual patches of similar material are scattered over the surface of the first andesite. The rhyolite appears to have been thickest in the vicinity of Columbia Mtn. and to thin out to the southeast. None of it has been found southeast of McLaughlan's well.

The intrusive rhyolite occurs on the summit of Columbia Mtn., where it has locally a sheet-like form and constitutes the ridge extending north of the mountain to the Adams mine. It is intrusive into the shaly rhyolite at the Conqueror mine, and another small mass cuts the first andesite, alaskite, and pre-Tertiary black jasperoid on the west slope of Vindicator Mtn. Thin sections indicate that some of this intrusive rhyolite occurs also on the east slope of Vindicator Mtn., but owing to the intensity of the alteration in this vicinity it could not be separated in the field from the silicified first andesite. The tuffs associated with these early rhyolitic eruptions may be best examined along the southwest base of Columbia Mtn. and directly west of the Kendall mine. Underground they are exposed in the west workings of the 100-ft. level of this mine.

After the eruptions of the earlier rhyolites came the eruptions of the second andesitic period, which covered the region with successive flows of andesite, accompanied by subordinate layers of andesitic tuff. The products of these eruptions constitute the most extensive formation in the district. The total thickness of this deposit, as of most of the other volcanic formations in this district, can not be determined, owing to the slight deformation of the rocks, their poor exposures, the comparatively slight topographic relief, and the absence of persistent datum planes, such as may usually be found in stratified rocks. It probably lies between 600 and 1,000 ft.; but this is confessedly little more than a guess and is likely to be under rather than above the truth.

The petrographic study of the andesites has not been finished. The second andesite undoubtedly includes more than one flow. Preliminary examination indicates that any division based on the predominance of certain ferro-magnesian constituents—for example, augite andesite or hornblende andesite—would be artificial. In other words, the relative proportions of these minerals appear to vary in any one flow. Moreover, as the first andesite and pre-Tertiary rocks are cut by dikes and small intrusive bodies of the second audesite, the latter formation as a whole is probably a volcanic complex, in which are involved intrusive bodies, as well as flows and beds of tuff and breccia.

The dacite, whose eruptions followed the second andesitic period, is in many respects the most interesting rock in the district and is certainly the most important from the economic standpoint. It occupies a considerable area east of Goldfield and Columbia and is the principal country rock of the Combination, January, Jumbo, Red Top, and Florence mines. The surface at the main Florence shaft is the second andesite, and it was at first supposed that the ore also occurred in this rock. Microscopic study shows, however, that most of the altered country rock of the Florence below the zone of complete oxidation, although finer grained than the typical dacite, is really a variety of that rock, and consequently that the shaft penetrates the flat-lying andesite and enters the dacite. This mass of dacite appears to be an intrusive sheet dipping gently to the west and south and cut off to the west by faulting.

A larger body of dacite extends southward from Tognoni Springs and forms some of the high hills just east of the mapped portion of the district. This mass makes up a large part of Preble Mtn. Smaller bodies of dacite occur southeast of Black Butte and in the central part of the district.

The dacite, of which typical and fairly fresh specimens can be collected on the little hill 500 ft. northeast of the transformer station, has the appearance of an andesite. It is generally more conspicuously porphyritic than the andesites of the district, but its essential distinction from them is the presence of phenocrysts of quartz. These are always rounded by magmatic corrosion and as a rule are neither very numerous nor very conspicuous. The rock consists of labradorite feldspar, hornblende, biotite, augite, and quartz in the usual andesitic groundmass. Chemical analysis of the dacite shows that it contains 60% silica, or 2% more than a hornblendic andesite from the northeastern part of the district. Mineralogically and chemically the dacite at Goldfield is merely a quartz-bearing andesite.

The geological relation of the dacite to the andesite is not entirely clear. Its comparatively coarse porphyritic texture, the irregular outlines of its exposures, and the occurrence of small bodies of dacite within larger masses of andesite are all indicative of the intrusion of the dacite into the andesite. As a rule, however, the contact between the two rocks is not well enough exposed or the rocks have been too much altered in its vicinity to afford definite proof of this relation. At one point only, situated one mile N 35° E of the summit of Preble Mtn., a sharp intrusive contact is exposed between the dacite and the andesite. The dacite is glassy at the contact and penetrates the andesite in a way that shows the latter to be the older rock. Of course, this exposure merely proves that one mass of the dacite is intrusive into a certain mass of andesite. The general conclusion reached, that the dacite as a whole closely followed the

andesitic eruptions and was intruded into the flows and subordinate tuffs at moderate depth, is still in need of evidence for its complete establishment. It is probable that this intrusion was accompanied by some deformation of the region, and the andesite flows appear to have been somewhat eroded before the next eruptions took place.

After the dacitic intrusion a rock provisionally classed as quartz latite was erupted as a series of flows and is now extensively exposed in the low hills in the southeast corner of the district. This rock, which corresponds more closely than anything else in the Goldfield region to some of the Tonopah dacite, is in most places a porous light gray or greenish rock with abundant glistening scales of black mica and phenocrysts of fresh paglioclase, mostly oligoclase. In some varieties quartz and orthoclase are present, and some thin flows of vitrophyric rhyolite are associated with the quartz latite. Two areas of rhyolite in the northeast corner of the district are provisionally mapped with the latite. The quartz latite is easily worked, and a quarry opened in this material 1½ miles south of Preble Mtn. has afforded stone for buildings in Goldfield.

No traces of mineralization have been found in the latite, and the ore deposits of the district were probably formed prior to its eruption. This, however, is not definitely determinable, as none of the latite occurs in the immediate vicinity of known orebodies.

After the latitic eruptions the region was covered by an extensive body of fresh water in which were laid down 500 ft. or more of bedded conglomerate, tuff, tuffaceous sand, pumiceous ash, and diatomaceous earth. These deposits, the 'cement rock' of the miners, cover a large part of the district, particularly in its outskirts. They underlie the town of Goldfield and stretch both north and south beyond the limits of the area studied. They also extend beneath the 'malapai' (*malpais*) mesa southwest of town and are well exposed in the steep bluffs of the ravine in which are situated the city waterworks. The beds here dip generally westward at angles ranging from 25 to 30 degrees.

Although the lake beds appear to be locally conformable with the quartz-latite flows, yet as these are present beneath them in only a small part of the district, and as the formation of the lake indicates some change in the configuration of the region, there is at least a suggestion of erosion between the quartz-latite eruptions and the lacustrine condition. Volcanism continued active during the existence of the lake, as shown by the prevailingly volcanic nature of the sediments and the occurrence within them of a thick flow of quartz-bearing basalt and thin flows of glassy rhyolite. The quartz basalt, as shown by wells, underlies the southwestern part of Goldfield and is exposed on the automobile road to Bullfrog.

In the eastern part of the district, northeast of Preble Mtn., are some bedded breccias and tuffs from 200 to 300 ft. in present thickness. They rest upon dacite and andesite and are made up largely of fragments of these rocks, particularly of dacite mingled with abundant fragments of volcanic glass and some sandy tuffs. These beds are provisionally correlated with the lake beds just described.

Lacustrine conditions were ended by the deformation of the region, the domical structure being accentuated or possibly initiated by this uplift. After the lake beds had been beveled by erosion and probably entirely swept away from the central part of the district eruptions of rhyolitic lavas again began.

The latest rhyolite is a light pink or pale brown rock, rather porous and containing abundant pumiceous fragments. It forms a flow of about 100 ft. in maximum thickness, which is exposed in the bluffs southwest of Goldfield, under the dark volcanic rock which caps the mesa. It is this rhyolite that is quarried for building stone at Rabbit Spring. It is in some places overlaid by a few feet of unconsolidated tuffaceous sand and volcanic gravel.

Finally, the volcanic history of the region was brought to a close by the eruption of one or more flows of olivine basalt. This is the dark rock that is conspicuous as the capping of the mesa southwest of town. It also forms the summit of Myers Mtn., Blackcap Mtn., and several hills south and east of the area mapped. The larger areas of this rock represent remnants of flows which rest upon a nearly horizontal surface of older rocks; but some smaller masses, such as that shown on the east slope of Vindicator Mtn., are intrusive and may fill orifices through which the basalt reached the surface to spread out as flows.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

Mineral sample from Ophir, Cal., marked O. T. W., is Graphite.

M. W. A., of Marysville, Mont., sends a piece of Limestone.

The mineral from Tehachapi, sent by F. A. F., is Chalcedony.

C. T. D., of Searchlight, Nev., sends specimen of Hornblende-Andesite.

The mineral from San Diego, marked W. M. J., is Magnetite, somewhat altered to Limonite.

The specimen from Santa Ana, marked W. H. H., is a Talc gouge, slightly graphitic; no value.

The black sand sent from Minersville, Cal., by G. H. W., is mainly Magnetite, with quartz and rock fragments. No platinum is visible.

The specimens from J. N. McL., of Denver, Colo., are: No. 1, Basalt; No. 2, a sulph-antimonite of copper and silver, probably argentiferous Tetrahedrite.

The rocks from Brayton, Ariz., marked R. McM., are: No. 1, Biotite-Granite; No. 2, Porphyry; No. 3. Breccia; No. 4, kaolinized rock stained by copper silicate.

Rocks from Grizzly Flats, marked F. C. B., are: No. 1, serpentinized metamorphic rock containing cubes of Pyrite; No. 2, Quartzite with Pyrite; No. 3, Gneiss with Pyrite.

The specimens from Caliente, Cal., marked C. F. B., are: No. 1, Pyrite in a decomposed Schist; No. 2, Quartz stained with Limonite; No. 3, Arsenopyrite; No. 4, Pyroxene rock with Pyrrhotite, Graphite, and Chalcopyrite.

The rocks from Wonder, Nev., marked W., are: No. 1, Quartz-Breccia, containing fragments of Chert and volcanic rock; No. 2, Quartz rock with the silver minerals, Cerargyrite and Argentite; No. 3, Rhyolite-Porphyry; No. 4, Granite-Porphyry; No. 5, Rhyolite; No. 6, Andesite; No. 7, Rhyolite; No. 8, Biotite-Porphyrite, containing Epidote.

How the Miner's Dynamite is Made.—III.

Written for the MINING AND SCIENTIFIC PRESS
By WHITMAN SYMMES.

The second half of the manufacture of dynamite consists in incorporating the nitro-glycerine with the 'dope' and in packing the product. The dope for ordinary dynamite consists of wood pulp (such as is used in the manufacture of paper), which is used to absorb the nitro-glycerine; precipitated carbonate of magnesia, which is added to neutralize any possible acidity in the nitro-glycerine or any acidity which might develop in the powder during storage and perhaps cause a spontaneous explosion; in some grades a little flour ('middlings') is used; and there is a liberal allowance of ground sodium nitrate (Chile saltpetre) for the purpose of oxidizing the wood-pulp and 'middlings.' It forms with them an explosive analogous to gun-powder.

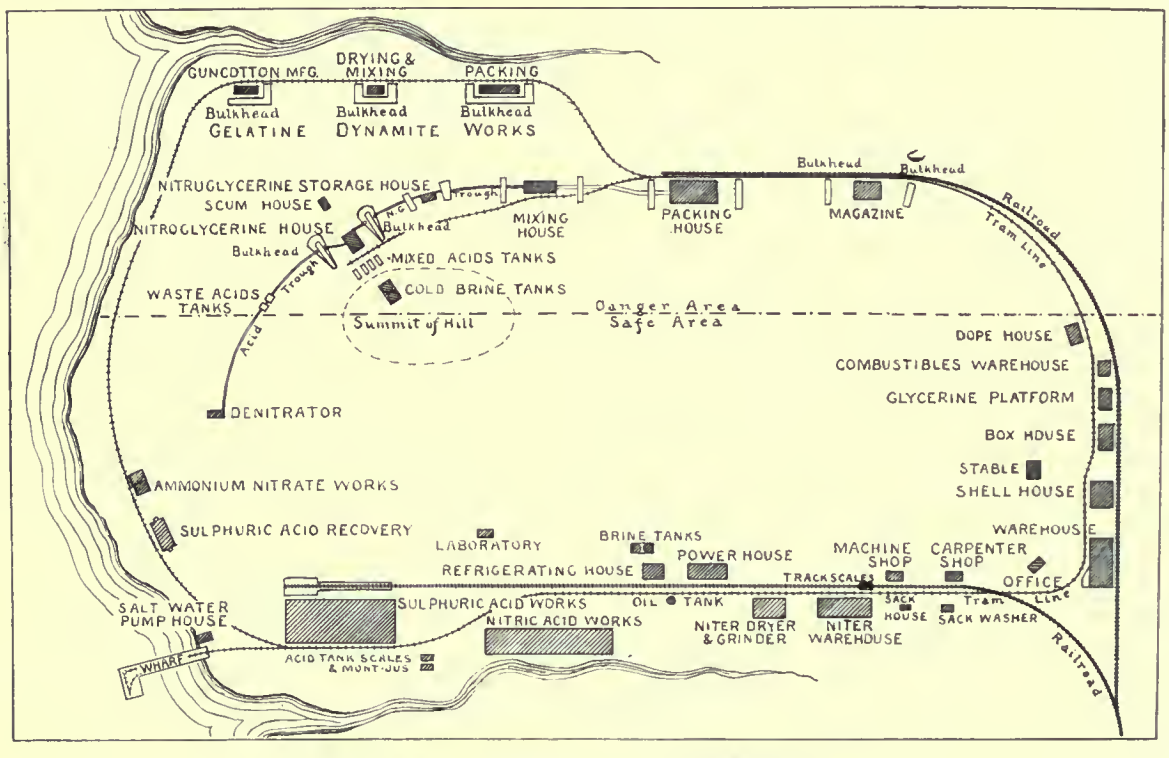
Hand-mixing is done in lead-lined troughs about 10 ft. ong, 3½ ft. wide, and 2½ ft. deep. The ingredients of the dope are sifted into the trough through a coarse sieve and mixed together. The nitro-glycerine is brought to the mixing-house through a lead or rubber-lined trough to a lead storage-tank. The amount required for mixing is weighed in a tank-scale, pushed to the mixing trough and run in through a rubber hose. The materials are then turned over with wooden spades until the mass is fairly even in appearance. It is next stacked up at one end of the trough and worked through a coarse sieve resting on the trough at the other end, being worked through by a reciprocating top covered with bristles. The sifting is repeated till the powder is of the proper texture.

Power-driven mills have been used for some years for the first part of the mixing and will soon be running at all the powder works. They are about 10 ft. diam., made of wood and hard rubber, and look like a four-wheel Chilean mill, except that the wheels are suspended a little above the bedplate and do not touch it at all. The powder is merely pressed down a little and a plow that follows each wheel turns the material over. These machines do the heavier part of the mixing, which is then completed by sifting by hand in the mixing-trough, as before.

The Vigorit Judson Works has lately added a special 'dope-house' in which the ingredients of the 'dope' are weighed and mixed. The latter is then conveyed to the mixing-house and incorporated with the nitro-glycerine. This arrangement keeps the mixing-house cleaner from the flying dust of the dope and allows that much work to be done at a distance from any danger of explosion.

Ninety per cent dynamite is made by mixing the nitro-glycerine with *kieselguhr*, a silicious earth composed of microscopic shells that absorb the liquid. It is not made on the Pacific Coast.

Kieselguhr was formerly much used in making dynamite, but it has been crowded out of use by wood-pulp. The latter acts as an absorbent and at the same time forms an explosive when in contact with the nitre that is put into the dope, thus adding to the strength of the powder. The highest grade of dynamite that is made with wood-pulp is 75%. The highest grade that is called for in quantity is 70%. Three different qualities of wood-pulp are used in making dynamite, those for the higher grades having more absorptive power. A special quality is imported from the East, but the grade principally used is made here in California.



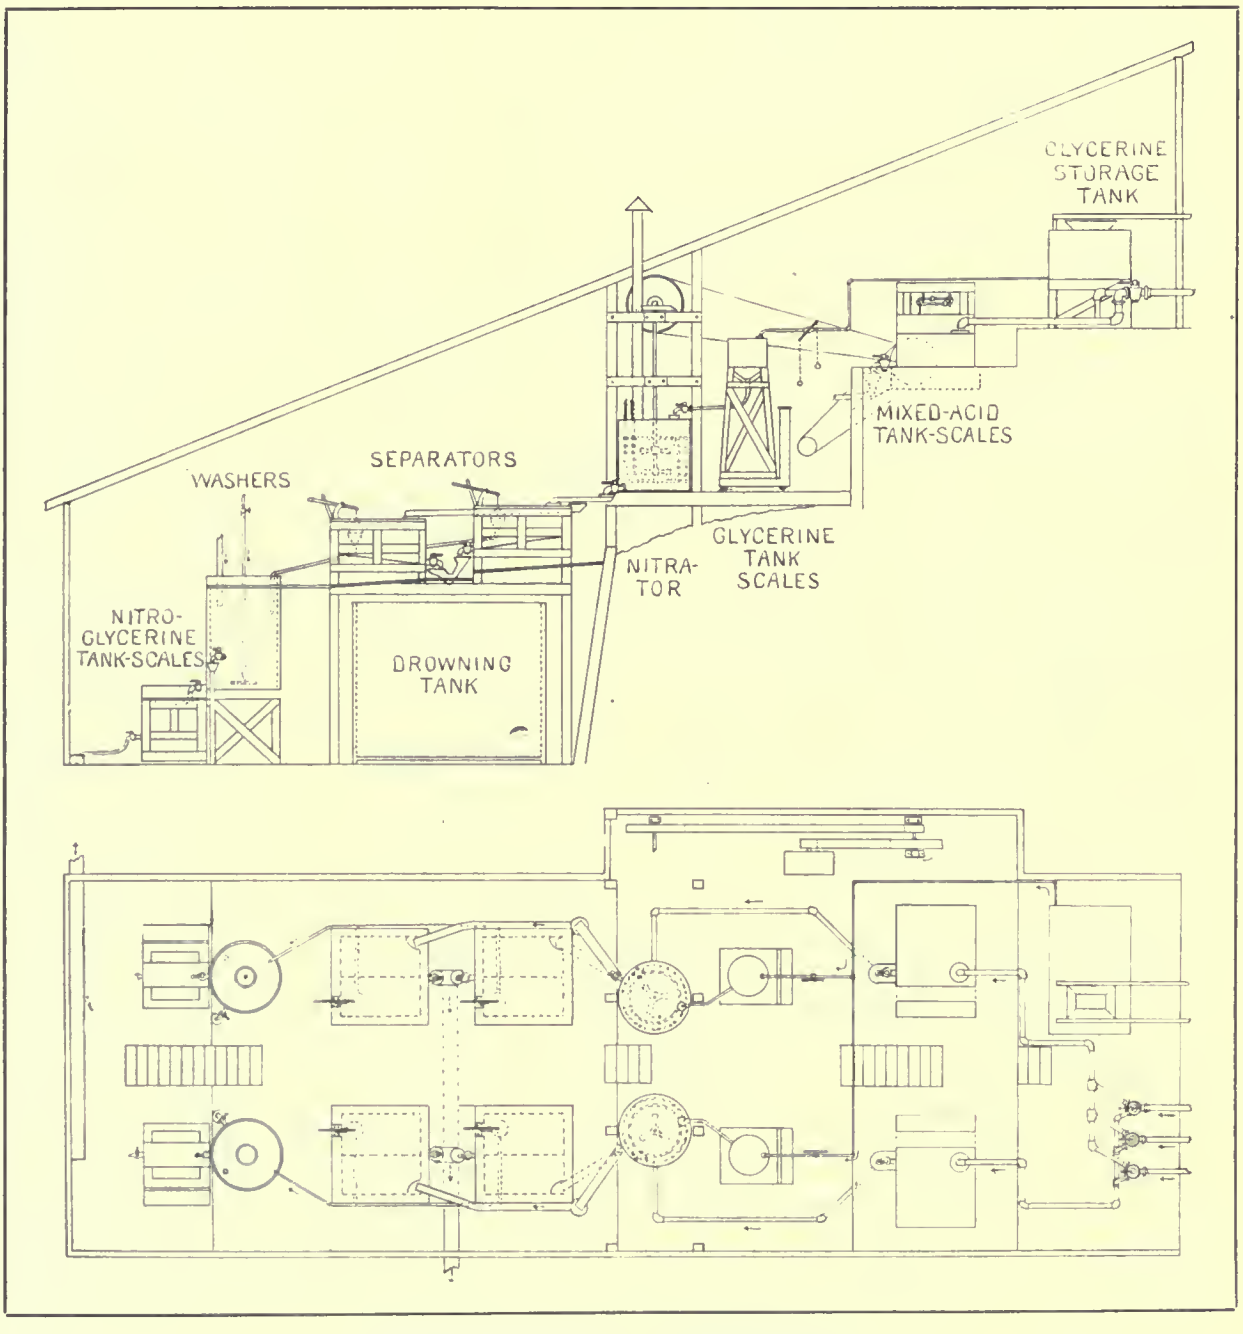
Arrangement of Buildings in a Dynamite Manufactory.

The essentials of a good powder are that the nitro-glycerine must have been washed entirely free of all acidity, and must contain a minimum of moisture, which, in the higher grades, may cause the nitro-glycerine to exude. The powder should contain a liberal supply of nitre for the purpose of thoroughly oxidizing the wood-pulp and 'middling' present to water and carbon dioxide. Carbon monoxide is much more deleterious in a mine than the dioxide. And lastly, what is generally considered most important of all, the powder should be mixed and packed to the proper consistence. In theory the most perfect explosive would be made if the nitre were ground very fine, so as to make an intimate mixture with the wood-pulp, but in practice such fine grinding seems to give less satisfaction. The powder is apt to pack into hard sticks in the packing machines, whereas the men I have worked with in the mines have always preferred a medium consistence, so that the powder will tamp well in the drill-hole. Furthermore, in the lower grades, a very dense powder might sometimes miss fire with an

XXX cap. After changing to medium grinding at the Vigorit, our powder gave excellent satisfaction and we never had a complaint. Different customers occasionally prefer dynamite of different density, and as we were always behind hand and packing 'to order,' we used to tell our packing-house forman to pack 'medium,' or 'soft,' according to what we knew of our customers' preferences.

All the four powder works on the Pacific Coast are today using practically the same formulas for the different grades of dynamite. What differences there are, are more carefully than the other grades, which never possess that fault.

After the nitro-glycerine has been mixed with the 'dope,' the meal is pushed in wooden cars to the packing-house, and is shoveled as needed into the trays of the packing-machines. The paper shells for the sticks of dynamite are rolled by hand in the shell-house by girls, who become wonderfully expert at the work. Some of them can stamp, roll, and paste as high as 8,000 in a day. Three years ago a machine was erected for rolling the shells, and machines will soon displace hand-labor. This



Nitro-glycerine House of a Dynamite Manufactory.

immaterial, and if the powder were packed to a density that suited me, I would just as soon use one brand as another. I give below the formulas for the principal grades of ordinary dynamite:

	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Nitro-glycerine	70	60.0	50	40.0	30.0
Wood-pulp	20	16.5	14	11.2	4.2
Ground sodium nitrate	7	22.5	35	46.2	60.0
'Middlings'	...	....	...	2.2	5.8
Precipitated magnesium carbonate	3	1.0	1	0.4	.....

In the 70% grade a little of the nitro-glycerine occasionally exudes upon the wooden packing case; therefore it is always well for miners to handle the 70% cases

will be an advantage to the works in more than one way, because it has not always been easy to get sufficient girls at the powder works, which are necessarily out of town. The shells are dipped, one hundred at a time, in molten paraffine wax, and are then allowed to stand at steam heat a few minutes to drain. After cooling they are conveyed to the packing-house.

The packing-machines in common use were invented by Col. W. R. Quinan, when manager of the Vigorit works many years ago. He afterward became manager of the California Powder works at Hercules, and from there went to the large dynamite works in South Africa.

The powder is packed by a series of wooden plungers—14 when packing 1¼-in. and 17 for the ⅞-in. size. The paper shells are placed in wooden molds to keep them from bursting under the tamping. The plungers are worked in unison by a bar and two levers in the hands of the operator, and ram the powder a little at a time. Some revolving pegs keep the meal stirred up and feeding properly. When the sticks are full the mold is removed by hand, the ends of the paper shells are pinched over, and the mold is then opened and the sticks of dynamite spilled upon a table. They are then packed in wooden cases, tried on a scale for net weight, and nailed up with a brass hammer. It takes seven men besides the boss to keep two machines busy, and each machine packs about 60 cases (50 lb. each) of ⅞ by 8 in. and 85 cases of 1¼ by 8 in. Large machines, power-driven, are now being built and will pack five times as much. Chinamen are commonly used for the hand-mixing and the packing, but they are not allowed in any other part of the works.

Gelatine dynamite is a variety that has gained greatly in popularity in the last few years. It is made by mixing a little 'soluble' gun-cotton with the nitro-glycerine, the gun-cotton having the property of turning the nitro-glycerine to a jelly. The 'dope' is then added, about the same as for ordinary dynamite. The mixing is done in a complicated power-driven mixing machine. 'Gelatine' in the name signifies that the nitro-glycerine has been gelatinized; it does not mean that there is any gelatine in the mixture. 'Forty per cent' gelatine dynamite contains 36% nitro-glycerine and 1.2% gun-cotton. The tetra and penta-nitrates of cotton are used, and not the hexa-nitrate, which is the ordinary variety of gun-cotton. The Judson works used to buy their gun-cotton from the California Cap Co. near-by, where it is made for mixing with fulminate of mercury and potassium chlorate in making blasting caps.

Gelatine dynamite cannot be packed in the Quinan machines, as they are made to handle a meal and not a dough. It is fed into a pyramidal worm, revolved by a handle, and is forced out as an endless cylinder at the small end of the machine, just as though it were a sausage. It is cut into sticks eight inches long and the paraffine paper is then rolled about it by hand.

Gelatinized nitro-glycerine is almost as waterproof as rubber and when placed under water it will not separate from its 'dope' as plain nitro-glycerine does. On account of its jelly-like consistence it is particularly valuable for tamping into 'upper' holes in wet mines, and the greatest demand for it comes from Colorado. California uses little of it.

The latest variety of dynamite, and one with which Pacific Coast miners may ere long become acquainted, is an improved form of ammonium dynamite. Ammonium nitrate is both an oxygen carrier and a substance that is easily decomposed into gases, without leaving any solid residue, as sodium nitrate does. Thus it makes a valuable component of an explosive, if properly employed. The difficulty of using it has been that it is strongly hygroscopic, that is, it attracts moisture from the air, just as kitchen salt does in a more moderate degree. Ammonium nitrate has been specified in patents on explosives, but generally it has been named together with tar, paraffine, nitro-benzol, or some waterproofing material that would coat the grains and keep them from contact with the moist air. Many experiments with ammonium dynamites were made on this Coast by my old friend, Chas. D. Kennedy, who was killed by an explosion while superintendent of the Judson works some years ago. Associated with him as chemist was N. L. Neilson, Jr., now superintendent of the Vigorit-Judson works. Both these men were most enthusiastic over the results they obtained. Lately a method has been invented of protecting the ammonium nitrate particles by incorporating a little vaseline, which is better for the purpose than the waterproofing compounds mentioned above. By this method ammonium dynamite is now being made both in the East and on the Pacific Coast, and thus far appears to have given excellent satisfaction. To give you an idea of its composition I will quote one of the Kennedy-Neilson formulas:

	Per cent.
Nitro-glycerine	25
Nitrate of ammonia	20
Wood-pulp	15
Nitrate of soda	40

This dynamite is equivalent in strength to an ordinary dynamite having 40% nitro-glycerine, and it can be manufactured for about one cent less per pound—not allowing for any patent royalties.

'Stump' or 'stumping' powder, much of which is sold on the Coast, is a 20% dynamite. It is made with 5% wood-pulp, 50% ground nitre, 20% ground coal, and 5% sulphur. It is a valuable explosive where a bursting rather than a shattering effect is desired. It is packed in two-inch cylinders 4 in. long, by ramming it into the paper shell through a funnel, without the use of machines.

'Low' powder is a 5% dynamite. It is packed loose in 50-lb. cases and can be poured into a churn-hole like black powder. It contains 5% nitro-glycerine, 70% ground nitre, 18% ground coal and 7% sulphur. The Judson 'low' contains 5% nitro-glycerine, 640 lb. nitre, 150 lb. ground coal, and 160 lb. sulphur.

Dynamite is most commonly tested at the works by placing a weighed charge beneath a heavy weight and measuring the effect in flattening a standard button of lead one inch in diameter and one inch long. The machine used for the purpose is known as the Quinan testing gun. A number of measurements are made with a micrometer upon the little lead cylinder, before and after firing the charge, and the averages are compared with the effects of a standard explosive, such as 90% Kieselguhr dynamite or a weighed quantity of nitro-glycerine. The dynamite is also examined by extracting the nitro-glycerine with solvents, such as ether, in the familiar Soxhlet's apparatus, purifying, and determining its weight; or by other analysis. The Mexican law requires the percentage of nitro-glycerine in dynamite to be within 2/10 of 1% of the mark, and it is not a bad law either. If a miner received 38% instead of 40% dynamite he would be paying more than half a cent a pound higher, comparatively. I am glad to testify, however, that as far as I know, the business has always been honorably conducted in the matter of living up to the label. The only exception is in the gelatine dynamite, where as shown above, 'forty per cent' means only relative strength and does not mean that there is 40% nitro-glycerine in it. During the days of the 'pool' some years ago it was customary to analyze samples from the different companies' shipments to make sure that the dynamite did not contain *more* nitro-glycerine than was stated on its label. Billing 40% dynamite as 35% would, of course, have been equivalent to a cut in the price.

Nitro-glycerine is a poison and acts on the system when used either externally or internally. Dissolved in alcohol it is known as 'spirits of nitro-glycerine,' or glonoin, and is official in the pharmacopœia. It is used in minute doses for stimulating the action of the heart.

The workmen in the nitro-glycerine house wear rubber gloves to protect their hands from the nitro-glycerine and acids. A headache may be obtained from nitro-glycerine in three different ways. If it is brought in contact with

the skin some of it is absorbed into the blood, generally producing a violent headache, which often lasts as long as three days. The same result follows with some men if they breathe the slight fumes that arise from nitroglycerine, especially when it is standing in the separators.

After the dynamite has been exploded, the gases of the explosion, consisting mainly of carbon dioxide and carbon monoxide, will cause a headache, and the smoke of the explosion is the only cause that the miner ordinarily thinks of. In this the monoxide is the greatest sinner, and it is for the purpose of thoroughly oxidizing the wood-pulp to the dioxide that so much nitre is used in the 'dope.' Some men soon get used to nitro-glycerine, so that they can handle it with impunity. The Chinese mixers and packers, for instance, get their hands oiled by it every day without its affecting them. But our superintendent at the Vigorit once stayed away from the works for six weeks and when he returned he got a 'powder headache' as though he had never been in the business before.

Because the manufacture of dynamite is a dangerous business mining men generally seem to consider that, therefore, it must be highly profitable, but that does not follow. It is now a better business than formerly, thanks to the improvements I have described. But a few years ago, when glycerine and nitre were both 'up,' the largest works on the Coast made a profit of less than half a cent per pound on 40% dynamite, and the smallest works made nothing, no allowance being made for depreciation and insurance in either case. Dynamite cannot be manufactured under favorable conditions in a plant producing less than 500,000 lb. per month. And good results can be obtained only by the most scrupulous attention to every stage of the process. The price of 40% dynamite at San Francisco has generally been 2c. per pound less than the price in New York, and scales, laboratory, and slide-rule have to be kept ceaselessly in operation if the best yields are to be maintained. The business has outgrown its early days and has now become systematized, exact, interesting, and, *ergo*, at last profitable.

The manufacture of dynamite should not be confounded in these results with the manufacture of smokeless powder, or of black powder. The California Powder Works manufactures both black and smokeless powder at its Santa Cruz plant, and the Giant Powder Works owns a black powder plant at Clipper Gap, Placer county, which is shut down by agreement. Both these classes of explosives are of small production when compared with dynamite, but their margin of profit on the Pacific Coast has been comparatively large. The price of black powder in carloads has been maintained at $1.50 per keg, whereas it is sold on the Atlantic side for less than $1. Similarly the price of smokeless, which is more or less hedged in by patents, is also maintained far above its actual cost. But dynamite, being of large production, and having had its price set in days of considerable competition, has never had any hot-house prices to flourish in. It has been brought to a position where its manufacture yields a decent reward for the application, skill, and risk that it demands, solely through the long chain of improvements introduced by its managers and employees.

In regard to the effect of the 'trust' upon the business it has taken over, I can testify, so far as the Coast companies are concerned, that it has been altogether for the good. Improved methods have been put in force, and machinery has been introduced that the managers wanted years ago, but which foolish boards of directors, whose principal hours were spent in other lines of business, did not think could be afforded. Under the Dupont 'trust' the managers of the different works in the United States are sent upon visits of inspection to the other plants. Reports are kept on the same form-sheets at all the works, and all reports are distributed to all the managers every month. Thus each manager is able to compare his yield of nitric acid, or of his de-nitrator, or the cost of packing his dynamite, with the cost at every other works in the combination. Profits have been increased, salaries have been increased, and wages of the best workmen have been voluntarily raised. The result of combination in other lines of industry may or may not have been of advantage to the country, but in the dynamite business the results, thus far, are unquestionably good. The investors receive more, the employees receive more, the plants are better, and therefore there is less risk of loss of life than there was before, and still the miner is able to buy his dynamite at the same old price.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

The owner of a mine was not liable for failure to furnish timber to be used as props to prevent a roof from caving in, as required by statute, where the person injured was an experienced miner, who knew the danger and continued to work in the dangerous place, after his demand for timber had not been complied with.

Patterson Coal Co. *v.* Poe (Ark.) 99 S. W. 538.

In an action to quiet title to a mining claim, the plaintiff must show that either he himself, or the persons from whom he claimed under a prior location, had performed ten days' worth of labor or improvements made by the 10th day of January of each year, for each 100 ft. in length along the vein until a patent was issued, and a failure to show such work or improvements in any year will prevent a recovery.

First Nat. Gold Min. Co. &c. *v.* Altvater, 149 Fed. 393.

A co-owner of a mining claim may, by *ex parte* proceedings, forfeit the interest of his co-tenant for failure and refusal to contribute to the necessary assessment work as authorized by statute. But such proceedings will be ineffective where no assessment work was in fact done as alleged in such proceedings. A court has power to review the representations made to the Land Department by a co-owner of a mining claim, to the effect that the other tenant had not contributed his share of the representation work during certain years, and that the applicant had published the notice provided by statute. And where the Court found that such representations were false, and that since the ground of forfeiture did not in fact exist, the mere publication of the notice did not conclude the co-tenant and was not effective for any purpose.

Delmoe *v.* Long, (Mont.) 88 Pac. 778.

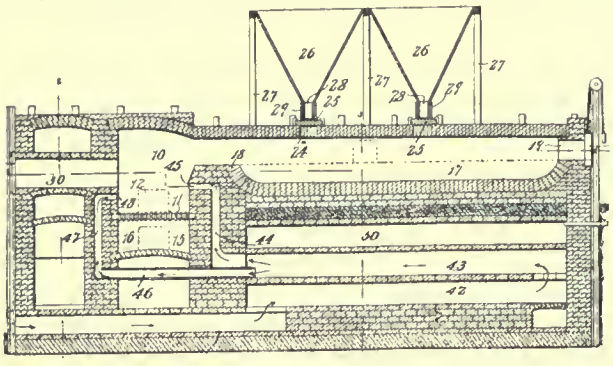
A purchaser of mines took possession and continued working the same. Within four months he learned that material misrepresentations had been made by the vendor as to the value and richness of the mines, but continued to operate the same for development and production for two years, until after suit had been commenced by the vendor to foreclose a mortgage given to secure the purchase money. No notice of an intention to rescind on the ground of the fraud had ever been given. The Court ruled that such delay and laches amounted to a waiver of the right to reseind, yet the purchaser could plead the resulting damages because of the fraud, as a failure of consideration as a defense to the action on the note given for the purchase money. But the purchaser, under such circumstanees, where he had not fully performed the agreement on his part, could not, with full knowledge of the vitiating fraud, continue performance, voluntarily subjected himself to damages, and then recover therefor.

Richardson *v.* Lowe, 149 Fed. 625.

MINING AND METALLURGICAL PATENTS.

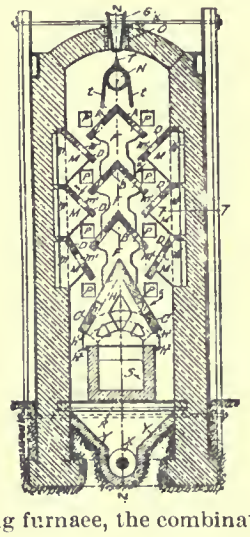
Specially Reported for the MINING AND SCIENTIFIC PRESS.

FURNACE.—No. 847,962; Harrison B. Meech, New York, New York.



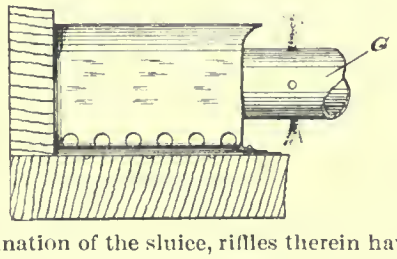
In an ore-smelting furnace, the combination with a reverberatory furnace-bed, of a cumbustion-chamber, a bridge-wall separating the furnace-bed from the combustion-chamber, a retort having its discharge end opening through the front wall of the combustion-chamber, and air-heating flues arranged below the furnace-bed, there being air-discharge openings in the front wall of the combustion-chamber at a point below the retort, said openings being in communication with the air-heating flues.

ORE-ROASTING FURNACE.—No. 847,756; George H. Franklin, Boulder, Colorado.



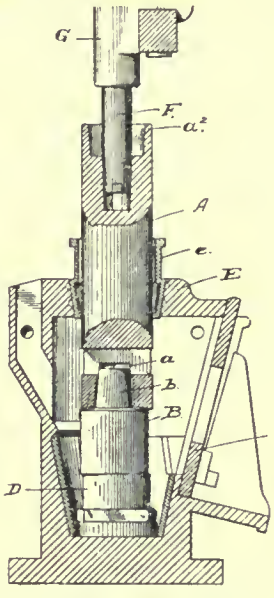
In an ore-roasting furnace, the combination of a roasting-chamber, a series of inclined shelves, of successively greater inclination from top to bottom, arranged one above the other within and extending from end to end of the chamber; with oppositely inclined shelves on the opposite sides of the chamber alternating with the central shelves, a feed-inlet at the upper end of the chamber, an outlet-pipe below the inlet and a divider and spreader interposed between the outlet-pipe and feed-inlet.

RIFFLE.—No. 847,519; John B. Sloane, Los Angeles, California.



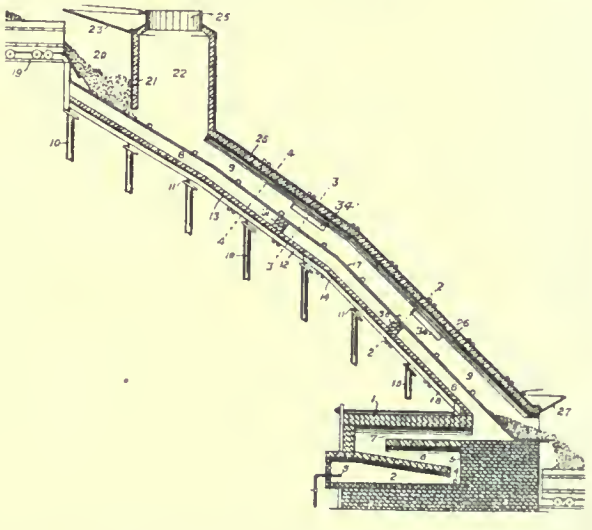
The combination of the sluice, riffles therein having vertical members, flat-bottomed members, curved top-members, said riffles being provided with perforations near the junction of the vertical and bottom members, also pipes in said sluice below the plane of the top of said riffles, said pipes having a series of perforations circumferentially spaced to project jets of water in opposite, that is to say, substantially vertical and horizontal directions.

STAMP-MILL STAMP-HEAD.—No. 847,397; Martin P. Boss, San Francisco, California.



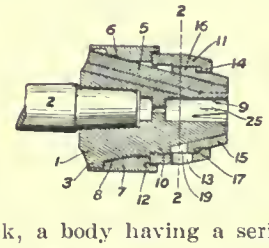
In combination with a mortar, having a cover with an anti-splashing housing, and a fixed guide above, a stamp-stem fitted in said guide, and a stamp-head fitted to the stem, and playing through the cover-housing, said stamp-head having an annular flange prolonging its upper end and adapted to pass over the fixed guide when the stamp-head is lifted.

MERCURY RETORT AND FURNACE.—No. 847,399; Conrad F. Brown, San Jose, California.



In a furnace of the character described, the combination of a combustion-chamber, a flue therefore, and a chute for the ore extending over said flue, the top of the flue forming the bottom of the chute, the walls of the flue and chute being formed at suitable intervals in their length with passages to permit the gases to pass from the former to the latter, and means for feeding the ore at the top of the chute.

DRILL-CHUCK.—No. 845,773; Lewis T. Gauss, Rochester, New York.



In a drill-chuck, a body having a series of converging grooves, a series of jaws having screw-threads, a screw-threaded part having threads for engaging the threads of said jaws whereby the jaws may be moved longitudinally in said grooves, and a rotatable cam-ring held on said body and having internal cams for engaging the backs of jaws

Editorial.

FOR THE CONVENIENCE of the men in our composing room, we have prepared a style sheet, which has been printed in pamphlet form. Any of our readers or contributors that care to have a copy of it for their own use can have one on request.

FILING SYSTEMS are numerous. The card index has simplified them and has permitted of a thoroughness previously attained only by laborious effort. On another page, Mr. Walter S. Brown gives a lucid explanation and illustration of a system intended mainly for the use of mining engineers.

DISCUSSION on sampling and assaying is always useful. In this issue we publish two contributions by experienced men on a phase of the subject recently brought into notice by one of those who had been nonplussed by contradictory results. Other readers are invited to give excerpts from experience.

A DESCRIPTION of a large smelting plant by the members of its technical staff is a document worthy of preservation. We have taken pleasure in abstracting a portion of such a description prepared by the gentlemen at Anaconda, who, under the leadership of Mr. E. P. Mathewson, have made the Washoe plant an example of good metallurgical practice.

AMONG THE ABSURDITIES of the present era is the idea that those who write about mines are necessarily good judges of them; many newspaper reporters have been misled by their fatal facility with the typewriting machine to suppose that they knew something about practical mining and the valuation of mining property. We read in *The Journal* of Baker City, Oregon, that a gentleman who "has been in the newspaper business for 10 years" and "has worked the biggest press syndicate in the country," has expressed an opinion on the Goose Creek copper district. It is stated that the gentleman's "opinion carries weight." We demur to that, the more so as it is further recorded that "he returned to Baker City wild with enthusiasm." "Exceeding his wildest dreams of wealth, the newspaper man was hardly ready to believe his eyes when he saw two miles of solid red metal lying on the earth before him." Mr. Journal, of Baker City, Oregon, we are surprised at you! Such balderdash! For we happen to have accurate information concerning Goose Creek. A trustworthy mining engineer writes to us, saying: "The mines have been known and worked, to cover assessments, for a great many years. Not one ton of ore has ever been shipped from them, and there was not one ton

of shipping ore on the six dumps I inspected at that time, nor has there been any development since then warranting the least statement as to values beyond prospects." Wherefore the enthusiasm of the Chicago newspaper man? Was it the expectation of using the press syndicate to boom the stock? There is a confusion of ideas lurking at Baker City. It is one thing to examine a mine and another to manage a press syndicate; at the present time there are lots of people who think that the working of a press syndicate to boost trash is mining. It is something altogether different, and closely akin to larceny.

Director of the Geological Survey.

TWO of our contemporaries have made the mistake of announcing that Mr. Frederick H. Newell has been appointed director of the United States Geological Survey, this statement being based on an erroneous press dispatch. Mr. Newell is chief engineer of the Reclamation Service, and it is of that bureau that he has been appointed director, the Reclamation Service having been separated recently from the Geological Survey, much to the advantage, we believe, of the latter. Although Mr. Charles D. Walcott has resigned as director of the Survey, to accept his appointment as secretary of the Smithsonian Institution, he is exercising supervision over both these scientific departments and is likely to do so until July, at least. Mr. Charles R. Van Hise, the president of the University of Wisconsin and the distinguished author of the treatise on 'Metamorphism,' has been urged to accept the post, but he has signified his desire to remain where he is, in order to give his services to the guidance of a broad educational movement in the upper Mississippi Valley. Mr. Willard S. Hayes, of whom we spoke on a recent occasion as having received the cordial endorsement of many of his colleagues, has strong support from within the body of the Survey and he has for several years acted as Mr. Walcott's assistant, a large part of the responsibilities of executive work having devolved upon him.

Another geologist mentioned for the office is Mr. W. B. Clark, of Johns Hopkins University, who has so successfully managed both the Maryland Survey and his own department in the university. He is leader of the State Geologists in the East and is considered to be a man thoroughly competent for the Federal office. Among the younger men Mr. Charles K. Leith and Mr. George Otis Smith are mentioned. Mr. Leith is well informed concerning the requirement of geological work in the West, having done some of the best of it himself. Mr. Smith is now in charge of the Petrography section of the Survey and of pre-Cambrian geology in New England. He is a vigorous man, with a broad training and unusual business capacity. Others have been mentioned and among them some of our more immediate friends, but it is from the names already given that a director is most likely to be chosen. We have referred to the subject because it is one of general interest to those engaged in mining; in fact, it is a good augury for the future of the Survey that the people living in the mining regions take so keen an interest in the successful administration of this scientific bureau. We hope that whoever the new director may be, he will escape the merely political and beaureaucratic tendencies that threaten all governmental efforts to direct scientific investigation and that, as far as possible, he will return to first principles—the splendid purpose and enthusiasm for science that marked the first organizer of the United States Geological Survey—Clarence King.

Since writing the above we have been advised that Mr. George Otis Smith has been selected as director. This appointment will give general satisfaction. Although only 36 years old, Mr. Smith is a man of experience in large business affairs. For nearly ten years he has been administrator of the Coburn estate and in that capacity he has done well. Therefore his administration of the Survey is likely to prove efficient. As he has been working with the Keep commission, he is thoroughly alive to the need of doing away with much of the red tape that entangles work at Washington. Moreover, and by no means least, Mr. Smith is a man of charming personality, so that he is likely to get cordial assistance from the men associated with him. To those that are engaged in mining in the West, it is gratifying to know that the new director is a man of no local experience, having done geological work in Utah, Michigan, Washington, North Carolina, and New England. Originally a petrographer, he has done his share of general and economic geology. We trust that under his administration the Survey may continue to grow in usefulness.

IN *The Bendigonian* we read that both the Federal and State Governments of Australia are taking steps to aid the repatriation of those Australians in Africa who are out of work and desire to return. The cost of bringing back 1,000 Australians is estimated at $35,000, which looks like a good investment on the part of their homeland. It bespeaks a worthy spirit.

WE OBSERVE that the Wellington Association, a group of philanthropists organized to sell mining shares at a price that puts them within the reach of all, has decided to be generous. The price of the Development stock "was advanced to 25 cents a share on February 28. It will soon be selling for 50 cents." A circular proceeds to say: "On account of the unavoidable delay in getting our February Success to our stockholders and clients, which did not give intending investors time to get in their orders by the time specified; we have set aside 100,000 shares of Wellington Development stock which we will furnish to that extent to the first orders received at 15 cents a share, payable $10 a month on each 1,000 shares." Of course, this offer is not intended for able-bodied men that can earn a living by attending to business, but for the orphans and widows, who are in want of help and are likely to get it from such generous distributors of gilt-edge investments. And the poor things that buy stock at 15 cents that is sure to go to 50 cents *soon*, are called 'investors.' In the dictionary of the impolite, they have another name.

By the Way.

At a recent meeting of the Royal Geographical Society of Cornwall, Mr. Richard Pearce delivered an address. Among other interesting things, he said:

I have recently been afforded an opportunity of comparing the relative value of the annual production of black tin, with the crude arsenic obtained by roasting the concentrate, at Dolcoath, from the year 1850 up to 1887, at which latter date, it appears, the sale of arsenic had entirely ceased. This indicates the gradual disappearance of arsenical minerals as depth is attained. The following condensed table shows the percentage value of arsenic sold, as compared with the sales of black tin:

	Per cent.
1850 to 1859	2.01
1860 to 1869	0.94
1870 to 1879	0.35
1880 to 1887	0.28

It has occurred to me that some additional evidence bearing on the association of tin with pyritic minerals might be of some interest, and I have been able, through the kindness of the manager of Dolcoath, to obtain samples of crude ore from five different points of the deepest workings in that mine ranging from the 440 to the 490-fm. levels. These samples, No. 1 to 5 inclusive, represent 275 tons of ore sent to the stamps, and may be taken as a fair average of the ore produced at those points. A careful determination of the sulphur contained in these samples has been made under my own personal supervision, with the following results:

	Depth. Fathoms.	Sulphur. %
No. 1	440 to 455	0.24
No. 2	455 to 470	Trace
No. 3	455 to 470	0.021
No. 4	490	0.053
No. 5	490	0.026

A careful examination of the samples that gave marked evidences of sulphur, especially No. 1, showed that the sulphur was evidently combined with iron in the form of ordinary iron pyrite, there being no evidence of arsenical pyrite, so that it may be said that in all the samples there was an entire absence of this latter mineral. If we then assume that the sulphur, as before suggested, is in combination with iron as iron pyrite, the following will represent the percentage of this mineral present:

No. 1	0.45	per cent iron pyrite.
No. 2	Trace	" "
No. 3	0.039	" "
No. 4	0.099	" "
No. 5	0.048	" "

The mean percentage of these five samples will be 0.126 iron pyrite, and if we omit No. 1 from the most shallow of these depths, we have a mean of 0.046% only. These results, I think, substantiate my view that the average of the crude ore produced from the mine would contain the insignificant "quantity of 0.0178% of iron pyrite." The above results, I think, prove most conclusively that pyritic minerals are not necessarily accompaniments of tin, as far as indicated in the particular case of the deep workings at Dolcoath.

In considering the question of the probable source of metallic ores, it may not be out of place for me to refer briefly to the formation of minerals by what may be termed artificial means, or by combinations effected in the ordinary processes of smelting metallic ores. In the Museum of Natural History, at South Kensington, an interesting and instructive collection of certain crystalline minerals may be seen, having all the physical and chemical characteristics of the natural minerals. They are, however, merely furnace products. This collection includes artificially formed cassiterite, augite, diopside, orthoclase, mica, rhodonite, willemite, magnetite, hematite, zincite, wurtzite, and galena. The majority of this series of minerals has been formed by crystallization from a fluid mass of molten material, others again by sublimation, and subsequent condensation on cooled surfaces. Perhaps the most interesting of this group, and one which more particularly appeals to us Cornishmen, is a beautiful crystalline specimen of cassiterite, said to have been found in the hearth of an Austrian tin furnace. The color of the crystals is unlike the native variety, being of a dark violet color. They are large and well defined, having the same crystalline form as the native mineral, but the propensity to twinning, which is found so abundantly in the native mineral, is curiously absent in the artificial variety.

In a somewhat lengthened experience my attention has been frequently drawn to a number of interesting examples of the artificial formation of crystalline compounds, as products from the smelting of ores, and it has often occurred to me that their formation may have, in some measure, been effected by causes similar to those which exist deep down in nature's laboratory.

The occurrence of metallic tellurium, as a beautiful crystalline sublimate, the brilliant octahedra of magnetic oxide of iron which has separated out from a highly basic slag on cooling, the formation of definite crystalline alloys of gold and silver, and of gold, silver, and lead, combiuations of sulphur with copper and lead and iron, indicate that artificial minerals may be produced iu the ordinary operations of smelting, which possess the form and composition of their primitive kin.

By way of example, I may draw your attention to the formation of metallic gold in the hearth of a reverberatory furnace, on which copper ore, containing gold and silver, has been smelted. It will be necessary for me to describe briefly the conditions which exist in the smelting of ores by such methods as are generally adopted. The aim of the smelter is to produce what is called a 'matte,' which shall contain the copper, gold, and silver in a more concentrated form than they originally existed in the ore. Normal matte may be said to consist of copper and sulphur with varying quantities of iron, together with certain impurities such as lead, arsenic, antimony, and bismuth.

If we study what happens when a mass of molten material in the form of matte is almost in constant contact with the upper surface of the hearth of the furnace, we find that absorption of molten matte by the hearth takes place, rapidly at first, when the hearth is new, and slowly increases, until a condition approaching saturation is reached. We find too that a separation takes place of certain easily fusible compounds of sulphur with copper and lead, so that a series of definite compounds are produced, having varying degrees of fusibility and specific gravity, and differing in chemical composition and physical characters.

The most easily fusible of these compounds find their way down below the smelting zone, and into the cooler parts of the hearth, where they crystallize out and form, frequently, an interesting series of products, not unlike, in some cases, certain minerals that occur in nature. Crystalline alloys of gold and silver, and gold, silver, and lead, have been found in the joints of the brickwork that forms the support of the hearth. In the case of the crystalline alloy of gold and silver, which has a high melting point, and therefore could not have reached the cool parts of the hearth in that form, there is abundant evidence to show that the metals were originally associated with lead, which caused their low fusibility, and that a secondary action had taken place, by which the lead became oxidized into minium or red lead, the alloy of gold and silver crystallizing out in all its purity, with a brilliancy of lustre, and a perfection of crystalline form, equal to the metals and alloys found in nature.

Personal.

CURTIS H. LINDLEY is at Salt Lake.

R. M. ATWATER is in South America.

ARTHUR L. WALKER has gone to New York.

EUGENE B. BRADEN is at Portland this week.

W. A. MERCER has left London to go to Russia.

J. D. HUBBARD, of Chicago, was in San Francisco last week.

H. LEUPOLD has left Buenos Aires on a journey into the Andes.

F. P. CADDY has received an appointment in Eastern Siberia.

L. W. WICKES is manager of the Ely Witch mine at Ely, Nevada.

FRANKLIN R. CARPENTER, of Denver, has been at Ely, Nevada.

C. C. EASLEY is superintendent for the Parral Corporation, at Parral, Mexico.

R. A. VARDEN has returned to London after a year's absence in South America.

CHAS. M. MACNEILL and D. C. JACKLING spent a few days in San Francisco.

WALDEMAR LINDGREN has been elected president of the Geological Society of Washington.

W. H. BLACKBURN has been appointed superintendent for the Tonopah Mining Co., of Nevada.

F. G. T. NICHOLAS has left Western Australia to accept an important appointment at Melbourne.

FRANK A. MOSS, of Kalgoorlie, has been elected president of the Australasian Institute of Mining Engineers.

J. V. N. DORR is consulting metallurgist for the New Southern Cross Co., whose mines are at Cable, Montana.

STANLY A. EASTON, manager of the Bunker Hill & Sullivan mine, at Wardner, Idaho, is visiting San Francisco.

R. C. TURNER has resigned as superintendent of the Tonopah mine, but he will remain at Tonopah for the present.

W. ROWLAND COX is in charge of the Dolores mines, at Matehuala, Mexico, for the American Smelters Securities Company.

W. G. KING, formerly of the School of Mines, at Butte, is now with Bettles, Mathez & Co., assayers and chemists, at Salt Lake City.

H. A. SHIPMAN has resigned as general manager of the Nevada United Mines Co., and JAMES A. SNEDAKER has been chosen managing director.

A. C. LAWSON, professor of geology in the University of California, has been lecturing on the earthquake before scientific societies at Washington.

F. CUSHING MOORE has resigned as chief engineer of the Federal Mining & Smelting Co., to resume the practice of his profession at Wallace, Idaho.

R. H. HAWLEY, for a number of years superintendent of the U. S. Smelting Co.'s plant at Canyon City, Colo., is now with SAMUEL NEWHOUSE, Salt Lake City, Utah.

ROBERT LINTON, of R. M. Atwater & Co., accompanied by R. DE SALIER, has just completed an examination of mining properties in Coahuila and Nuevo Leon, Mexico.

H. C. SCHMIDT has resigned as superintendent for the Minas Dolores y Anexas to become superintendent of mines for the National Metallurgical Co. of Matehuala, in San Luis Potosi, Mexico.

CHARLES E. CHRISTENSEN, mechanical engineer, who has been with Fraser & Chalmers and their successors, the Allis-Chalmers Co., for 28 years, at Chicago, has moved his office to the West Allis Works at Milwaukee.

FRANK ROBBINS is examining placer ground on the Colorado river and later in April he will make his usual visit of inspection to the nitre lands in Inyo county, California, returning to Los Angeles about May 1.

Publications Received.

BIENNIAL REPORT of the State Geologist of Missouri, by E. R. Buckley.

DEPARTMENT OF MINES, TASMANIA. 'Report on Cox's Bight' by W. H. Twelvetrees, Government Geologist.

RECORDS of the London and West Country Chamber of Mines. Vol. II, Part XV. By the honorary secretary, J. H. Collins.

'The Manufacture and Properties of Iron and Steel' by Harry Huse Campbell. This is the fourth edition of a book now well established in the esteem of metallurgists. Published by the Hill Publishing Co., of New York.

U. S. DEPARTMENT OF AGRICULTURE, Farmer's Bulletin No. 277. 'The Use of Alcohol and Gasoline in Farm Engines,' by Charles E. Lucke and S. M. Woodward. A 40-page pamplet of interest alike to agriculturists and mining men.

U. S. GEOLOGICAL SURVEY.—1. 'Mineral Resources of the United States,' 1905. Edited by David T. Day. This is a useful volume, the value of which would be greater if it were not fully one year overdue. 2. 'The Yampa Coal Field,' by N. M. Fenneman and Hoyt S. Gale. Bulletin No. 297. This is an account of a new coal area in Routt county, Colorado. 3. 'Economic Geology of the Kittanning and Rural Valley Quadrangles, Pennsylvania.' Bulletin No. 279. By Charles Butts.

Books Received.

'Concrete Factories,' compiled by Robert W. Lesley. An illustrated review of the principles of construction of reinforced concrete buildings, including reports of the U. S. Geological Survey, and the French rules on reinforced concrete. Bruce & Banning, Publishers.

'Long-Distance Electric Power Transmission,' by Rollin W. Hutchinson, Jr. A 350-page treatise on the hydro-electric generation of energy; its transformation, transmission, and distribution. A well-arranged book, combining theory with practical suggestions, which should be of value to designers and operators alike. The D. Van Nostrand Co., New York. Price, $3 net.

Mining Summary.

ALASKA.

NOME DISTRICT.

Reports state that the Lost Cabin placer mine has been found by prospector McLeod. It is on the Firth river, over the divide from Chandlar, running into the Arctic Ocean. Two men made the strike originally, took out $26,000 and started for the outside by way of the Arctic and Bering sea, but died before they could return.——It is reported that the Candle City district is doing well this winter, and it is expected that the clean-up will be $200,000 more than last year. The benches on Candle creek are showing up especially well. Coal is being mined regularly on the Inmachuk, and sells for $10 per ton since the heavy snowfall made freighting easy.——A quartz vein has been discovered on the upper part of Dry creek, in the Nome district. The lode was discovered by Lokke & Berg, while running a drift from the bottom of the 80-ft. shaft on their placer claim.

ARIZONA.

COCHISE COUNTY.

Deeds to 116 claims have been recorded, in the transference to the Superior & Pittsburg Copper Mining Co. of those claims included in the old Calumet & Pittsburg, Lake Superior & Pittsburg, Pittsburg & Duluth, and Junction mining companies. The Superior & Pittsburg company, known as the Cole combine, will operate all these properties, with L. W. Powell as superintendent.——On account of the rapid development in the Superior & Pittsburg, the Calumet & Arizona company is rushing the work on the new furnace for the smelter at Douglas, which will give the plant an additional capacity of 600 tons per day. The plant as now running has five furnaces, each with a capacity of 300 tons per day, and enough converters to handle the matte.——The Spray shaft of the Copper Queen company was closed about two months ago to give the timbermen a chance to straighten it. Shifting and sliding of the country had thrown it so much out of line that it could not be used below the 500-ft. level. This work has been completed, and the big hoist will be lined up with the collar, at once, and hoisting will start within a week. The closing of the shaft was a big handicap to the company, as it was a main artery and the biggest producer of ore in the district.——The new smelter to be built by the Shattuck-Arizona company will probably be situated at Douglas. Arthur Houle, who was connected with the Globe smelter, the Grand Encampment plant, and the Calumet & Arizona, will have charge of the design and erection of the plant. There will be two 400-ton furnaces, and a power-plant sufficient for double this capacity.——There is a shortage of men in Bisbee, but new recruits are constantly arriving, attracted by the high wage-scale. The companies continue to discharge men identified with the Labor Union, and the Western Federation of Miners is no longer considered a factor in the camp.

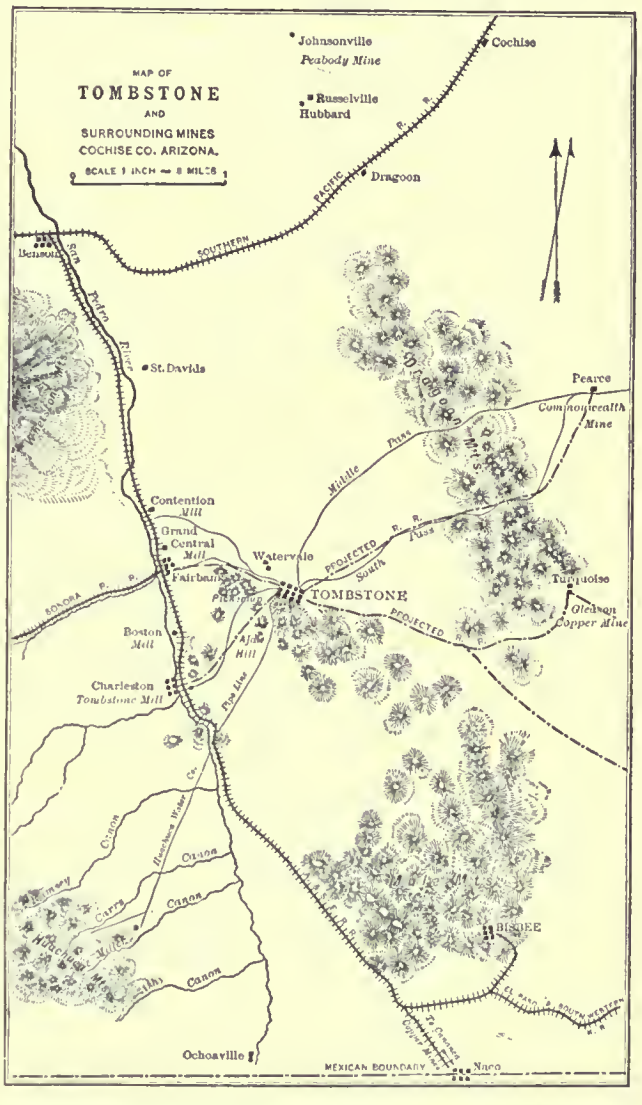
GILA COUNTY.

In the Old Dominion property, at the 70-ft. point in the second cross-cut on the 14th level, the entire vein will run 10% copper, and the vein is richest at the bottom. At No. 3 cross-cut, 100 ft. further along, they are in but a short distance, but the vein shows up here even better. Drifts connecting the cross-cuts are being run and will soon be completed, which will do much to improve the ventilation. The next move in the development will be to sink a winze to the 1,600 level, cross-cut to the vein, and then raise for a shaft.——At the smelter four furnaces are in commission, though one is not in the best of condition, and will probably have to be blown out for repairs. A fifth furnace, however, should be ready by June 1, and the management is considering the advisability of building a sixth.——No definite action has yet been taken regarding dividends, but it is officially stated that a substantial amount will be disbursed before the year is out.

GRAHAM COUNTY.

The New York-Arizona company, operating near Clifton, has let the contract for a 100-ft. shaft, to be sunk on the Louise claim. A gasoline hoist will be installed.——Several shareholders have recently visited the Cuprite property. Development has been going on for several years.——The Chase Creek property, near Metcalf, is being developed by a long tunnel. The workings have now attained a depth of 800 ft., and some ore has been encountered.

The Mitchell smelter, which was erected at Globe to handle the output of the Five Points property, has not been blown in yet, as it was found necessary to make some changes. It may be found advisable to delay this until the railroad is completed, which will be in about two months. ——The Gem shaft of the Globe Consolidated Copper Co. is down 575 ft. and cross-cutting is proceeding on the 500-ft. level. The shaft will be continued to the 1,100-ft. point, and the principal work will be on the 1,000-ft. level. At the Gray shaft, the drift on the 500 level cut the Lizzie vein, and a



drift is being driven on the 700 level, under Buffalo hill. The Globe shaft is down 480 ft., and sinking will be continued to the 800-ft. point.

PIMA COUNTY.

Pima county mines are shipping about 15,000 tons of ore per month, most of the ore going to Douglas for treatment ——The Mineral Hill company has 30 teams hauling ore A good body of ore has been developed on the 200-ft. level About 80 miners are employed, and E. B. Reeser is the manager.——The San Xavier mine is reported to have been sold. There is 5,000 ft. of development work, and 55,000 tons of ore have been shipped from the property.——The Calumet & Arizona company is working three diamond-drills on No. 99 claim, and about 10 holes will be put down 800 ft. on this property. Another drill is working on the Tom Hughes claim of the same company.——A good strike has been made in the Daisy mine of the Cleveland-Arizona company in the Silver Bell district. In cross-cutting the concentrating ore on the 100-ft. level, a large body of high-grade ore was encountered. The shaft will be unwatered and work will be resumed on the old 200-ft. level.

PINAL COUNTY.

(Special Correspondence).—The Saddle Mountain Mining Co. is enlarging its mining and smelting plants and the camp of Christmas is showing a rapid growth, having a population of about 1,000. The company is constructing a narrow-gauge railroad along the Gila river from the end of the grade of the Southern Pacific railroad to the hill leading up to the camp; and from the smelter to the camp a tram is being installed, the total distance covered by the railway and tram being three miles. About 100 men are engaged in the work. The production at the smelter of the company from March 1 to March 18 was 310,000 lb. of matte carrying 54% copper, produced with a blast-furnace of 200 tons capacity. The company has purchased and is preparing to install an additional furnace giving a combined capacity, when completed, of about 600 tons per day. The new three-compartment working shaft is down 140 ft., and it is expected that this shaft will have reached the 400-ft. level by the time the new smelting plant is finished. New hoists and boilers have been installed at the No. 1 and Hackberry shafts, and sinking has been resumed. George B. Chittenden is the general manager for the Saddle Mountain Co., and James W. Meyers is the smelter superintendent.

Phœnix, April 8.

Two new organizations, known as the Ray Copper Co. and the Gila Copper Co., have been formed to work the Ray claims on Mineral creek, above Kelvin, and the Kavanaugh group, adjoining this ground on the west and north. These organizations were effected largely through the efforts of Charles H. Cutting, who used to be with the Troy-Manhattan company.

CALIFORNIA.

AMADOR COUNTY.

A force of men is working in the shaft of the Burlington mine.——Nothing new has developed in the transfer of the Wildman mine and nothing is being done, except that the water is being kept out of the Mahoney, pending the settlement of the financial difficulties which seem to surround these properties.——Oil for fuel has been exhausted at the South Eureka, and all the men have been laid off, with the exception of the engineers and shaft men.——The air-compressor for the Keystone mine at Amador City has been installed, and operations in the mine have commenced again.

INYO COUNTY.

All the supplies for the 300-h.p. electric plant of the Casa Diablo Mining Co. have been shipped from Chicago and five miles of the eight-mile pipe-line have been finished. As soon as the water and electric plants are finished, fifty miners will be employed. A 30-stamp mill will be erected, as the vein has widened to six feet, and 3,000 tons of high-grade ore are on the dump and enough more in sight to justify this increase over the 10-stamp mill originally designed for the property. C. A. Frohman is the general manager and Charles Meier is the consulting engineer.——The Killian Mining Co. will get electric power from the Casa Diablo plant, and expects to soon start development work. L. B. Killian is the superintendent.——A good strike is reported in the Black Canyon property near Bishop. The ore is free milling and assays as high as $300 have been returned.

MONO COUNTY.

The Mono M. & M Co. has made the second payment to J. W. and Clarence Brown, on the Sacramento mine. The Cowser tunnel cut a 10-ft. vein at the 156-ft. point.

NEVADA COUNTY.

Some trouble is still experienced in Grass Valley, from the uncertainty of the electric power. The North Star company had to lay off the men for some days, owing to the temporary lack of operating power, and the bad air in the workings. The pumps are running to their full capacity. ——At the Empire, a full force is at work, and the mill and pumps are running, although temporary interruptions occur.——The Sultana shaft has not yet been unwatered to the 600-ft. level, and no mining operations are carried on.—— Development continues on the copper property at Iron Mtn., of which William Tarpie is the superintendent.—— The Gold Mound company of Spokane, which is operating at Deadman's Flat, has installed a new gasoline hoist and pump and is preparing for a busy summer.

PLACER COUNTY.

Some work is being done in the old quartz mine at Bird's Valley, near Michigan Bluff. This property was a producer 40 years ago.——Work will soon begin on the American, or old Alabama vein.——Work on the Imperial ditch has been suspended on account of the heavy snowfall.—— The width of the channel at the Home Ticket mine has not yet been determined, although it is known that the pay-gravel ranges from five to seven feet deep, and the channel has been worked 200 ft. wide.——A tunnel has been started to explore the Three Queens property, in Volcano cañon.—— The Hathaway, Butts, Kirkland, and Eureka mines of the Ophir Valley Mining Co., a corporation of New York men, lie on the north side of the ridge between Ophir and Newcastle. A tunnel 260 ft. long has been driven and a shaft 815 ft. deep has been sunk on the Hathaway, but this property was never worked below the 600-ft. level because power for pumping and hoisting was insufficient. The new company is installing new electric machinery, including a 75-h.p. motor for the Sullivan air-compressor, a 40-h.p. motor for the 10-stamp mill, and two smaller motors for the pumps and the coarse crusher. Power will be bought from the Bay Counties Power Co. A. B. Eastwood is the superintendent.

SIERRA COUNTY.

(Special Correspondence).— At Brandy City extensive development work will be done this summer, re-opening an old hydraulic mine that was closed down during the anti-debris agitation. The present owners have a permit to build a tailing-dam in Cherokee creek. There are several miles of flume to build to bring a supply of water to the ground, and a long bedrock tunnel must be run in order to run the tailing into Cherokee creek, instead of Canyon creek, where it was formerly dumped. A wagon-road will be built from Camptonville to Brandy City, and two sawmills will be installed to cut the lumber for the flume. J. R. Meek is superintendent.—— Gravel mining at Forest City is active. The South Fork is driving the main gangway, and expects to strike the Extension channel soon. At the Young America they are taking out pay gravel. At Alleghany both quartz and gravel-mining are active.—— H. L. Johnson has let a contract for the lower tunnel that is to tap the Tightner, to Gabe Nelson and others.—— The Oriental has closed temporarily on account of a break in the power line.—— The Plumbago is running with the usual force of men; they were hindered from running for a short time by the high water flooding the power house.—— The unprecedented storms of this winter have caused a great loss of property in the district. A snowslide carried away the bunk-house at the Sovereign mine and operations were suspended. At the Telegraph, on March 23, a snowslide carried away the mill, but missed the bunk-house about 50 ft. This is a severe loss, as some rich ore has been blocked out this winter. At the Keystone mine a large slide carried away the mill and a number of other buildings. The upper tunnels at the Buttes caved, and a large break in the ditch has caused the mill to hang up until the ditch is repaired. —— Notwithstanding the severe winter and continuous storms, there has been some new work done. John Costa has been driving a tunnel from the White Bear ground to tap the Excelsior channel, and has been in hard rock. The ground now is softer, and he expects to reach the Excelsior ground about July 1.——The West Point company has been running the main gangway in good gravel, and will soon begin breasting.—— At the Papoose mine, in Jim Crow cañon, a 10-stamp mill is being built that will be ready to run in about three weeks. George McGee is superintendent. —— At the Antler mine they are preparing to start a lower adit to the vein at great depth.—— In the American Hill district, several gravel companies are preparing to run long tunnels to tap the gravel channel that is known to exist there.—— The Sovereign company intends to begin extensive work, building a road to the mine from Sierra City, a sawmill, and stamp-mill.—— The Primrose has a lot of machinery in Sierra City to be moved to the mine as soon as the roads are passable.—— The Herkimer company

intends making extensive surface improvements.——The Poker Flat company will start work as soon as materials and supplies can be transported to the mine.——J. B. Kendell, of Tonopah, has an option on the Soda Spring mine on Canyon creek, and will soon start development work.——Sarat C. Rudra expects to start work in the Gold Point mine and cyanide plant soon.——Morse Bros., and McGee & Farrell have bought J. J. B. Corney's interest in the Comet mine. With the other owners, Geo. F. Taylor and Henry Spaulding, Jr., they will soon begin active development. The writer has visited this property a number of times, and it is one of the largest quartz lodes in northern California, and carries about $4 per ton. Heretofore it has been treated as a free-gold proposition; more than half the values are in the sulphides, which have been found to yield readily to the cyanide treatment. The present owners intend installing a larger mill and cyanide plant to treat the tailing.

Downieville, April 8.

TUOLUMNE COUNTY.

(Special Correspondence).—A report comes from the Jawbone district, east Tuolumne, which briefly tells of a rich strike having been made in the Lumsden mine. A cross-

California.—Showing Position of the Counties.

cut shows a 12-ft. vein, which assays as high as $200 per ton.——The mill at the Soulsby mine is to be started shortly.——The crew of 10 miners at the Santa Ysabel mine, near Jamestown, is soon to be increased. It is the intention to sink the shaft to 1,600 ft. Its present depth is 600 ft.——The Josephine mine, near Stent, has been bonded to H. M. Shaw. The price to be paid for the property is $12,000.——The Belleview mine, situated north of Soulsbyville, at which nothing has been done for many years, is to be reopened soon by a new company, the name of which has not yet been made know.——On April 1 the Bagdad-Chase G. M. Co. voluntarily increased the pay of all of its employees working underground. The working hours were at the same time reduced, the maximum shift now being nine hours, and the minimum eight. Under the present wage-schedule, machine men receive $3.50 per day, chuck tenders, $3.25, and muckers, $3. Besides this, the company has given to each of its 75 employees an insurance policy containing both death and accident clauses.

Tuolumne, April 8.

COLORADO.

GUNNISON COUNTY.

The Poverty Gulch district is situated seven miles northwest of Crested Butte and five miles from the Irvine mines. The first operations there started in 1880, on the Augusta and Excelsior properties, at an altitude of 12,000 ft., and a 2,500-ft. tramway was operated. A new company is now working these mines, and it is expected that they will again become producers.——Four long cross-cut tunnels are being run at Ohio Creek, a 100-ton mill is operating, and a 40-stamp mill is being built. The Carter tunnel of the Ashland company is in 2,700 ft. The 100-ton mill is at the Raymond property, and has been in operation over a year. E. M. Lamont is the manager.——The new mill is being built on the Gold Link, owned by the Colorado S. & R. Co. The tunnel at the property has been driven 2,600 ft. J. F. Pearsons is the manager.

SAN JUAN COUNTY.

The Anti-Periodic group, on Galena Mtn., has been sold to the Galena Mountain G. & S. M. Co. This property has been developed by 1,000 ft. of tunnels and raises, and small shipments have been maintained for some time.——Development work continues on the John Price group, south of Kendall Mtn., which has been leased and bonded by E. W. Ferguson. The tunnel on the Gold King vein is 575 ft. long, and follows a narrow lode all the way. A 50-ft. shaft connects with this tunnel.——The towers for the Aspen tram are completed and the cables are being stretched This line, which is independent of the Silver Lake tram, is three-quarters of a mile long, and will be operated by electric power.——Electric motors will be installed at the mine and mill of the Hamlet company. The mill-tunnel is in 700 ft., and will proceed at the rate of 200 ft. per month. When the tunnel is completed, a raise will connect it with the upper workings, and all the ore will be taken out at the mill level.——The Green Mtn. mill will be started April 1, if the repairs are finished. The plant has been thoroughly overhauled and it is expected that a better saving will be made under the new system. The company owns an 18-in. pipe-line, 4,000 ft. long, with a vertical fall of 230 ft., which will furnish power for mine and mill.——Some good ore is being taken out of the Ruby Basin mine, near Burro bridge, up Mineral creek. The mine has been worked all winter by contractors, operating principally on the Tornado vein.——Good progress is being made on the Wonderful group, belonging to the Precious Metals Co., situated in Mill gulch above Chattanooga. The vein was cut by a cross-cut tunnel, after running 300 ft. and gaining a depth of 150 ft. Driving is now in progress, on the vein.——The Henrietta property of the San Juan S. & R. Co. is being worked by lessees, and ore is shipped to the smelter that averages $28 per ton. The Colorado Iron Works is building machinery for a mill, for this company.——The Highland Mary mine, belonging to the Gold Tunnel & Railway Co., at the head of Cunningham gulch, has been closed on account of a disagreement among the stockholders.——The Gold King mill is turning out about 75 tons of concentrate per day.——The Gold Prince mill is running steadily, and by April 1 the mine will be working at its full capacity and the 100 stamps will be handling about 500 tons of ore per day.——The Detroit & Colorado M. Co., shipped 13 cars of ore to the Ross smelter during February.——The Yukon tunnel, of Boulder Mtn., trending from Cement creek to the Uncle Sam, is now in 2,550 ft. Several veins have been encountered.

IDAHO.

SHOSHONE COUNTY.

The Bunker Hill & Sullivan has paid its 114th dividend, which was $180,000, making a total of $8,406,000 to date.——Drifts are being run east and west on the vein of the Independent mine, and some concentrating ore has been disclosed. The vein is holding well in size.——Development work is being pushed on the Star group of 17 claims, which adjoins the morning mine on the west and is controlled by Finch & Campbell, of Spokane. E. H. Mollitt is the manager. The group includes three veins, the first of which was cut by the new tunnel, which is in 1,100 ft. The mine is equipped with a six-drill compressor and owns a power-line three miles long, from the Morning compressor to the mine.——The Hecla mine at Burke continues its steady production. The shaft is 900 ft. deep, and three levels have been driven from it. The 900-ft. level has been driven for

1,000 ft. in the ore-shoot, and is proving to be in the richest horizon yet encountered. The new sorting and conveying-belt recently put in operation at the head-frame is working nicely and results in a better grade of concentrating ore being shipped to the mill. The company will install a new electric hoist with a capacity of 2,500 ft., and will then sink below the 900-ft. level. J. R. Smith is the president of the company, and James F. McCarthy is the manager.——A new shoot of high-grade ore has been encountered in the Hennessy-Burns group of four claims. The ore was found when the tunnel was in 120 ft., the 10-in. pay-streak coming in from the hanging-wall side. This property is situated seven miles east of Burke, on the Idaho-Montana summit. ——Good concentrating ore has been cut in the Sailor tunnel, on Slate creek, about 14 miles south of Wallace. The vein is 14 ft. wide and has been test-pitted for 800 ft. The group contains six claims and the owners are principally Wallace people.——Two properties on Terror gulch are working steadily. On the Golden Queen group the cross-cut is in 380 ft. and has 140 ft. to go, to cut the vein. The Terror Con. Co. is driving a tunnel on its vein.——Along with the regular monthly dividend of $20,000, the Success management is sending out the announcement of the strike of an entirely new ore-shoot, which was found by extending a drift on the No. 3 level, above the lower tunnel. The new orebody is nearer the granite hanging wall than any shoot previously opened. The Success now employs 75 men, and is turning out 1,000 tons of zinc and lead concentrates per month. This mine was originally known as the Granite, and 14 years ago was one of the camp's big producers, but was closed down and abandoned after about $1,000,000 had been paid in dividends.——The Pittsburg company's mill started March 1, and has since been running steadily.—— The Snowstorm company has declared another dividend of $45,000, in spite of the fact that the mine only ran 16 days in February, on account of the blockade of the Northern Pacific railroad.

MONTANA.

FERGUS COUNTY.

The most important development in a mining way witnessed in Lewiston in some time was the recent sale of large blocks of stock in the North Moccasin mine to a party believed to be acting for the Kendall company. The sales were made on the basis of a $500,000 valuation for the Drake property, each shareholder getting a chance to sell his stock at $1 per share. The deal can only mean that the North Moccasin is to be taken over by one of the big companies. The prevailing impression is that the Barnes-King company will ultimately take over the Kendall and Moccasin, as all these properties are now being examined and sampled.

MADISON COUNTY.

The Unity Gold M. Co. has been formed in Omaha to work the Kearsarge mine, near Virginia City. Ten men are already at work, and the shaft will be sunk 700 ft. This property produced a large amount of gold about 40 years ago, from surface workings, but there is not a deep shaft on the property, or anywhere in Madison county, and therefore operations on this property will be watched with interest. ——A rich strike is reported in the Bedford mine of the Ramshorn mining district. A 28-in. vein was uncovered in a winze below the tunnel, and 10 in. is galena, with some copper. The property is owned by Francis Redfern, and three carloads of the ore are ready to be shipped to the East Helena smelter.

MISSOULA COUNTY.

Reports received in Spokane are that T. L. Greenough and associates have gained control of the stock of the old Iron Mountain Mining Co. The property lies east of the Cœur d'Alenes, five miles north of De Borgia, and was at one time a great producer of silver and lead, but it has not been worked for eight years. The workings consist of one shaft which was sunk to a depth of 1,800 ft. Work was suspended when a law was passed by the Montana legislature to the effect that every mine must have at least two exits. The orebody is 350 ft. long, and the ore having been taken out to so great a depth as 1,800 ft., the owners were in doubt if enough ore could be mined to pay for driving the long tunnel which would tap the ore-shoot at a great depth. Work was started last spring on a cross-cut tunnel which will be driven nearly two miles. Eight power-drills are being used, and the tunnel is being advanced at the rate of 50 ft. per week. It will require three years more to finish the big bore.

OREGON.

CURRY COUNTY.

(Special Correspondence).—A vein is reported on the property of the Chetko company, of which A. E. Imbler is the superintendent. A cross-cut has been run 50 ft., into some good peacock-copper ore. This property is in Curry county, within 18 miles of the Coast.

Ashland, April 8.

JACKSON COUNTY.

(Special Correspondence).—The Ashland antimony property, which was discovered last summer 11 miles south of Ashland, and on the southern slope of Ashland peak, has been leased and bonded to the Chapman Smelting Co. of Oakland, which makes a specialty of treating base ores. This property contains stibnite ore, running 60% antimony. Operations will be commenced on this property at once, and the ore will be shipped to Oakland for treatment.

Ashland, April 8.

WASHINGTON.

OKANOGAN COUNTY.

The Copper World M. Co. will install a hoist as soon as the snow is off Palmer Mtn. The vein is 25 ft. wide at the bottom of the shaft and is reported to be shipping ore, principally iron sulphide.——In the cross-cut on the 300-ft. level of the Copper World Extension mine 30 ft. of soft mineralized material has been intersected. The hanging wall has not been reached.——A body of ore rich in ruby silver has been uncovered in the Horn Silver mine, and some of it will be shipped as soon as the roads are clear of snow.——A blind vein of copper ore, three feet wide, has been encountered in an adit on the Palmer Lake group.——The Little Chopaca mine, on Little Chopaca Mtn., is being reopened, and good indications are reported.——A fine body of silver-lead ore has been opened in the lower adit of the Favorite mine.—— The Ruby mine, at the base of Mt. Chopaca, on the Similkameen river, which has paid expenses from the grass roots, is now in a position to ship a considerable tonnage of both high and low-grade ore. Railway transportation over the Victoria, Vancouver & Eastern railway will probably be available in a few weeks, as the rails are being laid between Oroville, the present terminal, and Nighthawk, about three miles distant from the Ruby mine. The roadbed passes the Ruby within a stone's throw of the lower adit.——At the Phil Sheridan mine, about 14 miles northwest of Republic, a winze has been sunk below the upper adit level, a shaft is down 106 ft. and drifts have been driven 251 ft. on the adit level. All of those openings are on a vein, three to five feet wide, and the average value of the ore extracted is said to be $63 per ton, most of which is silver. The winze gives a total depth of 141 ft. on the vein.

Republic, March 30.

BRITISH COLUMBIA.

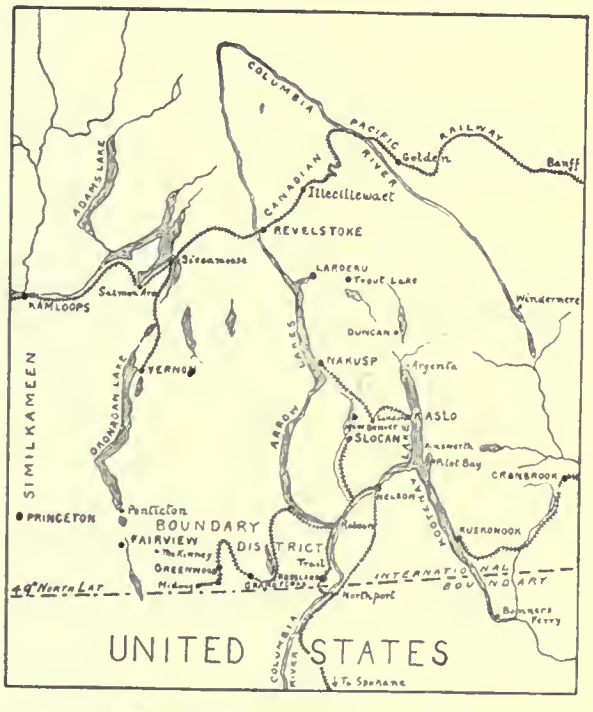
The shipments from the Rossland mines for the week ending March 30 were as follows: Centre Star, 2,320 tons of ore; Le Roi, 2,555; Le Roi No. 2, 525; White Bear, 80. Total for the week, 5,480 tons.——The installation of the new hoist at the Centre Star is making good progress. The electric locomotive that was installed this week on the 350-ft. level, and which is used in hauling ore and waste from the War Eagle to the Centre Star shaft, is working satisfactorily. The shaft is now 50 ft. below the fourteenth level and will soon reach the fifteenth level. Surface work on the Idaho continues, and also work by drifts extended in from the fourth and twelfth levels of the Centre Star.—— At Le Roi there is a good chance for an increased production. The shaft has reached the 1,650-ft. level, and will be extended by contract work. The pipe-line being laid from the Black Bear compressor to Le Roi will soon be completed. A small hoist is being erected on the Spitzee, but will soon be supplanted by a larger one.——It is reported that M. R. Galusha, manager of the Jumbo mine, has raised

sufficient funds to continue work on this property, which has shipped several thousand tons of ore in the past.

At the smelter of the Consolidated company, at Trail, there were received during the past week 5,663 tons of ore. In addition to the ore that came from Rossland mines, the following sent ore to this smelter: St. Eugene, Moyie, 425 tons; Snowshoe, Phœnix, 115; Eureka, 27; Aberdeen, 12; Arlington, near Erie, 22; Midnight, 8; Myrtle, 23.——Two furnaces are running at Northport, and coke is coming in good quantities.

The following were the shipments from the Boundary mines for the week ending March 30: To B. C. Copper Co.'s smelter from the Mother Lode, 4,200 tons; from B. C. mine, 180; from Emma, 140; from Snowshoe, 950. To the Dominion Copper Co.'s smelter from the Brooklyn mine, 2,016 tons; from Rawhide, 1,856; from Sunset, 640; from Mountain Rose, 72. To Trail smelter from the Snowshoe, 700 tons; from Riverside mine, 30. To Nelson smelter from the Emma, 30 tons of ore. The total shipments for the week were 27,244 tons of ore, and the total for the year to date, 221,747.

The total smelter receipts in southeastern British Columbia for the week ending March 30 were as follows: Grand



Map of Part of British Columbia.

Forks, 16,390 tons of ore; Greenwood, 5,470; Boundary Falls, 4,584; Nelson, 319; Trail, 5,483; Northport, 1,056; Marysville, 600.

Latest advices from Spokane seem to indicate that the consolidation of the Giant and California companies is progressing, and that the shareholders are unanimously in favor of the merger. W. Y. Williams will probably have charge of the property. The development on the California consists of a 300-ft. tunnel and a 50-ft. shaft, and a 10-drill compressor is on the ground. The Giant has shipped some ore, carrying a high percentage of molybdenum.——The fuel and car shortage which has seriously affected the production of the Granby works for the past few weeks has been overcome and the plant is now treating about 3,000 tons of ore per day, one record run of last week having been of 2,940 tons in 24 hours. Eight furnaces will probably be running in a few weeks. If the labor difficulties with the Crow's Nest coal miners is amicably settled, the fuel question will probably not bother this district any more.—— Development is to be resumed at the Prince Henry mine this month.——Work will be started on the Last Chance property, adjoining the Bug Copper property in West Copper camp.——Electric machinery will be installed at the Crescent mine, two miles below Phœnix.——The big crusher at the Mother Lode property of the British Columbia Copper Co. is now being driven by electricity instead of steam, as was the original arrangement.——A new boiler and hoist are being installed at the Moreen mine, in Deadwood, and the mine will be operating in two more weeks.——For the past few days there has been but one furnace running at the smelter of the British Columbia Copper Co., owing to the difficulty in securing sulphide ore from the Napoleon mine while the roads are in such bad shape.——The Cariboo mine, at camp McKinney, is to be unwatered and sampled. The ore carries good zinc values.——Good ore is being stoped at the Bay mine, a mile from Greenwood, but no shipments are made on account of the bad roads.

MEXICO.

The Cabrera and American properties have been consolidated under the name of the Virginia & Mexico M. & S. corporation, of which Jesse Scobey is the manager. A reduction plant of 150 tons daily capacity will be erected.

CHIHUAHUA.

The Veta Colorado M. & S. Co. will equip its property with a 250-ton mill. New York men control this property, which is situated at Minas Nuevas, seven miles from Parral, and is adjoined by the Veta Grande and Los Muertos. The Quebradillas mine, which forms the nucleus of the company's property, was opened less than 10 years ago, but is now developed by three shafts. The Veta Colorado vein is being worked from the Santiago inclined shaft, which is 1,000 ft. deep, with levels at each 100 ft. The electric pumps, when installed in the shaft, will have a capacity of 1,000 gal. per minute. The company has just completed a new power-plant for generating electricity that will be used at the mine and mill. While the present capacity of the Santiago shaft is only about 100 tons per day, the new central shaft, as soon as it is connected with the workings, will be able to handle 750 tons per day. At the 300-ft. level, which is the highest from which ore is being hoisted, the pay-ore is about 75 ft. wide. About 10,000 ft. of development work has been done, and the company has been shipping 2,500 tons of ore per month to the Mapimi and Torreon smelters, netting $13 per ton from Mapimi and $11 from Torreon. John W. Conner is the manager, and about 400 men are employed.—— The Cia. Minera Ramon Corona de Naica, of the Naica district, began shipping ore to the Torreon smelter last week, and will be a steady shipper henceforth. George Stinson is the manager.—— It is stated that a smelter is to be built by the Mexican Gold Copper Co. at the mines of that corporation in the Guaynopa district. C. H. Hadley is the superintendent.—— W. B. Brooks is erecting a concentrating plant to work the sand of Ocampo creek. It will have a capacity of 40 tons per day.

The Oxnam Prospecting Co., an English corporation, subsidiary to the Palmarejo & Mexican Gold Fields, Ltd., of London, has started its 75-ton reduction plant This company is operating the Guerra al Tirano mine, about 25 miles from the Palmarejo property, in the Chinipas district. Sufficient ore is blocked out to run the mill for three years, above the 400-ft. level. Development work has been suspended, pending the arrival of pumps. An extraction of 88% is obtained in the mill by dry crushing and pan-amalgamation. W. A. Pomeroy is the manager.—— A 25-ton water-jacket furnace is being erected at the property of the Mexican Mines Syndicate, at Urachic, in the Rayon district of the western part of the State.——The new mill of El Rayo M. & D. Co., of Parral, has started. Bert Peterson is the manager.—— The Illinois Zinc Co., through its manager, T. F. Noon, has taken an option on Jose Lago's Las Plomosos zinc mines, about three miles from Picachos, near the Conchos river. The property consists of 190 *pertenencias*, and the ore is zinc sulphide, carrying some lead. A diamond-drill will be used in prospecting the ground.

JALISCO.

The Copper Range Mining Co., of Chicago, owning copper properties in the Autlan district of the State, has purchased a 50-ton copper smelting furnace. The property is in the municipality of Purificacion, and a good deal of development work has been done.

Special Correspondence.

Joplin, Missouri.

Big Output of Lead and Zinc Ore.— Successful Drilling Operations.— A New Mill.— Handsome Dividends.—Ore Under Webb City.— General Activity.

The week ending March 16, 1907, marks the biggest value for zinc-lead shipments ever recorded in the Missouri-Kansas district for one week. The total value for both minerals makes the handsome sum of $435,846, over $40,000 greater than any other one week, and the week ending March 23 was not far behind it. The highest price paid for zinc ore both weeks was $53.50. The highest price paid for lead ore was $85 per ton. The car situation is easing up, the railroads supplying a large number of coal-cars at the present time.

Shipments.	Zinc ore. Lb.	Lead ore. Lb.	Combined value.
Week ending March 16	14,366,760	2,018,470	$ 435,846
" " " 23	12,289,710	2,983,750	418,370
Up to date	143,267,140	21,584,600	4,288,370
Same period last year	120,024,880	16,673,640	3,291,555
Increase	23,242,260	4,846,960	996,815

The Alpha Mining Co., operating at Spring City, south of Joplin, has been a steady producer of 50 to 60 tons of zinc ore and 10 to 12 tons of lead ore for the past several months. The property is owned by Judge Pfost and

Sketch Map Showing Position of Joplin.

others, of Kansas City, and is a splendid paying proposition. The vein on which they are working lies in a draw, but keeps its flat dip into the side hills. They are working on the 100-ft. level, carrying a seven-foot drift, five feet of which is a sheet formation of pronounced richness. The character of this ore deposit is likened to troughs between ribs of flint, the lode being a conglomerate of lime, zinc ore, and lead ore. Burt Lyon, who has been drilling on the south 10 acres of the Rob Roy Mining Co.'s land, has gone through an 80-ft. layer of limestone into a bed of silicate, which the drill shows to be 40 ft. thick. This is a new occurrence in this district, as zinc ore is always encountered below the lime, if any mineral at all is found.

The Continental Zinc Co., one of the biggest companies in the district, owning a large acreage of land in Joplin, and also in the Webb City-Carterville district, is building a 300-ton mill on their land at Webb City, and is planning an innovation, the hoisting machinery having self-dumping skips instead of the regulation tub or can and cable. With this improvement it will be possible to hoist 1,000 tons of dirt, whereas 300 tons per shift has been a good record under the old way.—— The Morning Hour mine on the Marion B. Mining Co.'s lease of the Henderson land west of Joplin will, at the declaration of its next dividend, return to its stockholders the full sum invested, and future dividends will be velvet. Three dividends of 25 cents each have already been declared. This mine has been the wonder of the new field southwest of Joplin. From the present outlook at the property the company will realize many more dividends.

Col. James O'Neill, of Webb City, who purchased the fee of four acres in the south edge of Webb City from the estate of the late General John W. Noble, of St. Louis, reports that the sheet ground, or blanket vein, is being proved to exist over this tract, being encountered at the 180-ft. level. This establishes the existence of the blanket vein of zinc on the south of that city, as well as the north and east, and property owners are wondering if it is not possible that the entire city is underlaid with a rich lode. Seventy-five feet of ore is the report of the drill cuttings on the Jesse Trent land, three miles south of Granby. This new location of a deep ore deposit at a distance from any tested ground renews the interest in an extensive occurrence of rich zinc-lead ore around the mother camp of the Missouri-Kansas district. Mr. Trent owns 560 acres of land, and this is the first deep drill-hole put down, but it is his intention to keep a drill operating to determine the extent of the orebody.

Toronto, Canada.

Shipments From Cobalt.—Rush of Prospectors to New Districts.— Important Discoveries.— Difficulties of Access.—Larder Lake.— News From Cobalt.

At Cobalt, shipments of ore for the week ending March 30 amounted to 238 tons, the following being the shipping mines: Coniagas, 32 tons; Nipissing, 58; O'Brien, 72; Trethewey, 50; Townsite, 21; Right-of-Way, 2 tons. The Right-of-Way shipment was consigned to the Anglo-French Nickel Co. at Swansea, Wales.

The spring rush of prospectors is mainly in the direction of the new camps at Elk lake and Lady Evelyn lake, and other points on or near the Montreal river. The value of the deposits is now fully established. Willet G. Miller, the Provincial geologist, returned this week from a trip of inspection from the new district, and confirms the statements of valuable discoveries. The southern portion of the new field lies about 25 miles west of Cobalt, and about six miles north of Lady Evelyn lake, in the Temagami Forest reserve, the formation extending northward to Elk lake, an expansion of the Montreal river. Prof. Miller encountered great difficulties, having to drive 45 miles over ice, which was rapidly breaking up and covered with water, but succeeded in examining some of the finds. He reports that the geological conditions are similar to those of Cobalt, the deposits carrying cobalt bloom and smaltite, together with native silver and other minerals. Though no finds have yet been made showing a richness comparable to those at Cobalt, yet the similarity of geological conditions, and the substantial character of the veins uncovered, indicate that the district is one of great possibilities. So far the deposits north of Lady Evelyn lake have been found to occur in the diabase. At this point much development work has been done. On Elk lake almost the entire township of James has been staked and many locations made to the west in the Temagami reserve, as well as farther up the river. Notwithstanding the dangerous condition of the ice, many prospectors are going by sleigh up the river.

Liverymen at Latchford charge $10 per day for teams, and require a deposit covering the value of the horses as a security. As soon as navigation opens the Elk lake area will be accessible by steamer, as there are navigable stretches of water on which boats will ply, though transfers will have to be made at a couple of portages, and

there is also a water route from the river, west to Lady Evelyn lake. The T. & N. O. railway is building a branch to Charlton, 18 miles from Elk lake, which may be pushed through to that camp if the development justifies it.

The Larder Lake district is now being surveyed and laid out into townships. The Larder Lake Proprietary Mines Co. is undertaking development on an extensive scale. They have 26 teams at work taking in plant and material, including a stamp-mill and ten tons of dynamite, and are putting up camp buildings to accommodate 100 men. The Barnard's Point Gold Mining Co. has shipped to its claim a plant comprising a Rand compressor, a 25-h.p. boiler, hoist, etc. John Macdonald, late of the Silver Queen, Cobalt, has been engaged as superintendent.

The Beaver mine, at Cobalt, has changed hands, and has been taken over by a new company known as the Beaver Consolidated, of which F. L. Culver is president. Development is being pushed. Three shafts are being sunk, two of them being 45 and 50 ft. deep respectively. William Shovell, formerly superintendent of the Big Master gold mine in the Manitou Lake district, has been appointed superintendent of the Columbus Cobalt. The Rochester Cobalt has installed a new steam-plant, and the main shaft is down 45 ft. Some fine specimens of native silver have been taken out. Further work on the vein struck on the Peterson lake property, supposed to be the bonanza Nipissing vein, has been prevented owing to flooding. The draining of the lake to a lower level will be undertaken when the spring freshets have subsided.—— The litigation over the Lawson mine, one of the most valuable of the Cobalt properties, which has prevented development, has at length been terminated by consent of the parties. The settlement is practically an agreement to accept the judgment first given in the case.

Salt Lake, Utah.

Revival at Pioche.—The New Railroad.—Silver King Consolidation.—The Cactus.—Ohio Copper Co.—Sale of the Annie Laurie.

Information has been received from Pioche, Nev., to the effect that the contractors who will undertake the construction of the Pioche & Caliente railroad, are assembling equipment, and that grading of the new line will begin within ten days. Mining activity at Pioche is very pronounced at this time. A mining deal of considerable significance has been consummated whereby W. A. Clark, of Montana, has come into possession of the E. & F. company's mines, near Bristol.

The new mill of the Jennie Gold Mining Co., at Gold Springs, Iron county, has been placed in operation. Preparations are under way for the resumption of work at the Ophir mine in Stateline district. The property has been idle several years.

The Daly Mining Co., operating at Park City, has levied an assessment of 25 cents per share, or $37,500, to be used for development purposes. In the Naildriver mine a body of galena and carbonate lead ore has been opened in the east drift on the 950-ft. level. Shareholders of the Keith-Kearns Mining Co. have authorized the directors of that corporation to take steps toward a coalition with the Silver King Mining Co., and shareholders of the latter will meet in a few days to act on the same matter. It is proposed to organize what is to be known as the Silver King Amalgamated Mines Co., which will control something over 1,500 acres of territory in Park City.

It has been stated by reasonably good authority that Augustus Heinze and associates have secured an option on the Scheu silver-lead properties in the Good Springs, Nevada, district. An official statement from the management of the Columbus Consolidated Mining Co., of Alta, Utah, showed a cash balance on hand of $100,000 on April 1. Ore shipments have been light during the winter months on account of poor transportation facilities. This difficulty, however, will soon be overcome and it is stated that quarterly dividends of $60,000 will continue indefinitely.

Ore and bullion settlements as reported by Salt Lake banks last week amounted to $521,600.——High-grade silver-lead ore shipments continue from the Utah mine, of Fish Springs, Juab county. The last shipment netted $33,037, showing values of 151 oz. silver and 47% lead. ——The Beaver Copper Co. has been organized, with Henry Catcow as president, and A. J. Bettles first vice-president. This company has absorbed the Beaver Lake Copper Mining Co. Preparations have been made to conduct an active campaign of development. Heavy mine equipment will be installed. It is the intention to sink a double-compartment shaft to 500 feet.

During March the Newhouse Mines & Smelters corporation marketed 3,000 tons of concentrate and 500 tons of crude ore, from the Cactus copper mine in Beaver county. Regular shipments of ore are being made from the Cedar mine near Milford, which nets about $70 per ton.

Contractors working in the Butler-Liberal mine at Bingham have encountered a body of lead ore of shipping grade at a depth of 125 ft. in the Liberal shaft. Good headway is being made with the construction of the Ohio Copper Co.'s mill near the Dalton & Lark mine. Orders were placed with the Minneapolis Steel Machinery Co. for the structural steel some time ago, and the General Electric Co. has since been awarded the contract to furnish the electrical equipment.——At the receiver's sale of the Annie Laurie mine, this property was bid in by George Baird, representing the Kimberly estate of Sharon, Pa., for $220,000. The Annie Laurie mine is situated in the Gold Mountain mining district of Piute county. It is the intention of the new owners to operate the property in the future.

Denver, Colorado.

Woman's Invasion of Mining.—The Ibex Dump.—Crested Butte District.—E. E. Burlingame.—Ore in Depth at Cripple Creek.—El Paso Annual Report.—Zinc Resources of British Columbia.

The invasion of the fields of masculine endeavor by the eternal feminine seems to be destined to continue until there remains no stronghold that man can call solely his own. Cripple Creek is represented at the New York mining exhibition by a lady prospector and mine-owner, who attracts much attention. Next will come the lady miner, and then the masculine domination of our arduous profession will be at an end.

The Ibex dump at Leadville is to be treated. A feature of the new mill will be its system of distributed units for the furnishing of power, electricity being the power chosen. Card tables have been installed where one would usually expect to find Willleys. The fact that the Wilfley was for a considerable period far superior to any other type of table to be obtained has tended to prevent later tables obtaining the best opportunity to prove their merits. More recently many millmen have come to realize that the exposing of the fine concentrate to the unprotected action of the wash-water on coming to the end of the upper riffles is, with many ores, decidedly a disadvantage, and types of tables that do not possess this feature seem likely to establish themselves as soon as they become better known.

The Crested Butte district, in the west-central part of the State, is eliciting some present interest. This was, with the exception of Pikes Peak, the first district to be mapped and to have a geologic folio issued by the United States Geological Survey. While possessing some old producers of importance, the district at present languishes, partly because of the need of better transportation facilities.

In the death of E. E. Burlingame, Colorado has lost an honorable metallurgist, who for many years conducted the assay-office so well known throughout the West. Probably no assayer in the country was more favorably known, or bore a more enviable reputation. Mr. Burlingame was one of the old school of self-taught metallurgists; without formal training beyond a fundamental grounding in chemistry and assaying, he came as a young man to Central City in the early days and soon demonstrated his ability to such a degree that he was appointed Territorial Assayer. In 1876 he established the business that bears his name, and conducted it until five years ago, when the active direction passed more directly into the hands of his son. The sorrow of his family is shared by a wide circle of acquaintances and friends, who also feel the loss a personal one.

That Cripple Creek is not slowly sinking into a decline is shown by the recent strike on the 900-ft. level of the Gold Sovereign mine on Bull Hill. Thirty-five feet of good ore has been opened up and further development is under way. While undoubtedly the rich veins throughout this district will be fewer at a great depth, there seems no reason to believe that the impoverishment will ever be very marked.

The report of the Commission appointed to investigate the zinc resources of British Columbia contains much that is of interest to Colorado mining men. The portion by Mr. W. R. Ingalls, which takes up more than one-third the report, deals with the various ores of zinc; magnetic, electro-static, and flotation processes for their dressing; wet methods and smelting processes for the extraction of zinc; the design of a zinc smelter, and the valuation of ores. The description of the deposits by Messrs. Argall, Garde, and Barlow is of much value, as is the discussion of methods of assaying that follows.

The annual report of 1906 of the El Paso Gold Mining Co. has been received by the shareholders. The gross production for that period was a little over $800,000, being slightly lower than the estimates made before the close of the year. Dividends to the amount of $171,500 were paid during the year. The El Paso property, consisting of 70 acres, is situated on the west slope of Beacon hill, at Cripple Creek. Development work amounting to 4,400 ft. was done principally in the upper levels above the present water-line, which is at a depth of 600 ft. No new orebodies were encountered. S. S. Bernard in the report has included a list of the amounts pledged by the various subscribers toward the cost of the deep drainage adit, as the El Paso mine will be one of those properties most benefited in the driving and early completion of the adit. The amounts are as follows:

El Paso	$100,000	U. S. R. & R. Co.	$ 12,500
Mary McKinney	60,000	Eagle Ore Co.	5,000
Portland	40,000	Gold Dollar	5,000
Elkton	60,000	C. S. & C. C. D. Ry. Co.	12,500
Granite	15,000	F. & C. C. and M. T. Ry.	12,500
Strong	10,000	Work G. M. Co.	5,000
Golden Cycle	25,000	Gold Sovereign	1,000
Vindicator	15,000		

It is expected that the new cyanide tailing plant of the Portland mill at Colorado City will be ready for operation in April. The plant will have a capacity of 300 tons per day, treating the enormous dump accumulated from the chlorination mill. A belt-conveyor will be used to transmit the tailing from the dump to the mill.

London.

Gold Mining in India.—Results From the Three Big Mines.—Prospects in Depth.—Hopeful Spirit.—Esperanza Returns.—Continued Car Shortage. —El Oro Output. — Camp Bird Production. — Large Profits.

Three of the big Indian mining companies' reports have appeared this month—Mysore, Nundydroog, and Ooregum. At the twenty-seventh ordinary general meeting of the premier mine—the Mysore—the chairman was able to congratulate the stockholders on the results of the past year. These were recently referred to in my correspondence. Dividends aggregating in one year £418,674, equal to 14s. per 10s. share, or 140% on the issued capital, may well draw forth language of jubilation from the chairman of a public company. But his enthusiasm was even greater when he came to dilate on the bountiful future in store for the stockholders. Were it not for the chill shadow of the diminished returns in the neighboring Champion Reef mine, owing to impoverishment at depth, Mysore shares would probably stand at a higher price today than the $30 for the $2.50 share, although it must be owned that the present dividend yield of about 11% per annum on that figure is none too much. Reverting to present prospects, the underground developments during the past year are described as having exceeded in extent, importance, and value those recorded within any similar period in the history of the mine. The reserves of ore have been increased by 134,000 tons, making a total of 747,000 tons, or about four years' output. It is the hope of the directors that they will have 1,000,000 tons opened up as reserves in about two years more, and by that time Edgar's shaft—a perpendicular shaft going down through the country—will not only be finished, but, it is expected, also fully equipped and at work, and then with the increased reserves and greater facilities for hauling from the deeper levels, there is a prospect of still further increasing the already handsome returns. In support of these views the chairman reminded the stockholders of the scale on which the mine had been opened up. They had six main shafts distributed over a distance a mile long, and varying in depth from 250 to 3,500 ft. deep. In estimating the reserves, the chairman remarked that not one single ton of ore has been allowed to enter into the calculation below the bottom of the shafts or the bottom levels, and he thought they would see that the amount remaining available as reserves under foot is many times more than the actual reserves blocked out, so that, even if mining in depth were no longer possible, the life of the Mysore mine could be measured by tens of years. Many of the readers of the MINING AND SCIENTIFIC PRESS, obliged to keep within the limit of hard facts in daily practice, may regard this imaginative forecast as bold prophesying. Still it will serve to cheer the mining speculator on his way. He is often enough bewildered by professional stocktaking phraseology which leaves him in doubt as to whether he ought to 'bull' or 'bear' some particular stock. Having regard to the present assay-values found at the deepest points of the mine "lodes 4 ft. and 5 ft. wide worth 2 oz. and 3 oz. to the ton," the chairman of the Mysore could afford to make good sport of the pessimists. He remembered they were told that when they got to the bottom of the old workings at 300 ft. they would find the lode cut out. Another prophecy was made that it would disappear at 1,000 ft.; and three years ago in an article, written and also delivered before the learned societies, they were told for certain that the lode was going to cut out at the 3,000-ft. level.

The Ooregum has been the least successful of the three Indian gold mines mentioned at the beginning of this

articlе, during the past year. On a production of 68,881 oz. bar gold, dividends were paid amounting to £54,687. Compared with the previous year, although better results were obtained in respect of the grade of the quartz, the weight of gold won, and the reserves of ore opened up, there has not yet been a general improvement of a character sufficiently substantial to warrant an increase in the output during the current year. The appearance of the mine favors further developments at depth and for this purpose and to introduce improvements in the surface plant, the directors recommend an increase of the company's capital.

The directors of Camp Bird (Colorado) have reeeived a report on the working operations for the quarter from November 1, 1906 (the date on which the new mill of 60 stamps commenced crushing), to January 31. The following are extracted: The mill during the above period crushed 20,770 tons of dry ore; receipts from bullion sold (including cyanide products), $569,713; receipts from concentrate sold, $69,892; total, $639,605; less working expenses (including development, transportation, and treatment of product), $158,344, leaving $481,261.

The manager advises that on January 31 the value of the unrealized product on hand and in transit on that date was $89,297. There has also been expended on construction account for the above period, $5,768; for re-construction, $9,021. In order to regain the normal position of the company, and in accordance with the policy laid down by the chairman in his speech at the last annual meeting, the ore milled during the quarter was above the average. On January 31 the total dry ore broken in the stopes amounted to 108,246 tons. Everything at the mine and mills has progressed satisfactorily, and a high state of efficiency been maintained throughout. The report for February states that: The mill ran 27 days and crushed 5,331 tons of ore (dry weight), yielding 9,971 oz. bullion, and approximately 556 tons of concentrate. Amounts received from sales of product effected during the month as follows: Bullion (including cyanide bullion), $173,977; concentrate (681 tons), $38,695; total, $212,672; less expenses, $53,745. Balance, profit at the mine, $158,927.

Regarding the Nundydroog, the broad results of the company's operations for the past decade are set out in the following table:

Map of Mexico.

Year.	Quartz crushed. Tons.	Gold from all sources. Fine oz.	Net sum realized. £	Dividends. Per year. %	Dividends. Amount. £
1897	49,675	54,201	211,397	42½	93,500
1898	37,930	40,080	156,196	27½	63,731
1899	35,200	42,158	164,115	30	72,600
1900	37,460	46,798	182,518	33¾	81,675
1901	52,030	54,937	214,268	37½	90,750
1902	55,940	56,072	218,171	40	96,800
1903	66,860	67,912	264,458	45	108,900
1904	75,840	66,296	258,155	42½	102,850
1905	79,070	68,161	265,251	36⅔	100,580
1906	81,750	69,947	272,385	36⅔	103,767

Since crushing was commenced in 1882 the total amount of ore milled has been close upon 700,000 tons, yielding a little over 701,000 fine ounces, realizing £2,732,573, of which sum £1,241,027 has been distributed in dividends among the shareholders, representing about nine times the original capital.

February returns from two of the Mexican mines are announced. At Esperanza the mill ran 26 days, and crushed 11,942 tons of dry ore; shipped to smelter, 1,703 tons of dry ore; estimated realizable value of bullion produced, $125,222; estimated realizable value of concentrate, $53,286; estimated realizable value of ore shipped to smelter, $87,245, leaving $265,753; receipts from rents and other sources, $1,043; total, $266,796. Less working expenses, $139,752; allowance for depreciation of plant, $2,500; consulting engineers' fees and New York office expenses, $2,521, making $144,773; profit, $122,023. Feet of development work, 784; shipping ore on hand, 1,400 tons. The manager reports that the shortage of cars still continues.

The following is the February return of El Oro Mining & Railway Company:

The No. 1 and No. 2 mills both ran 27 days, and together crushed 20,306 tons of ore, producing	$163,278	
Less working expenses	$85,725	
Development expenses	8,274	93,999 or $4.63 per ton
		$69,279
Profit from railway		4,448
Total		$73,727

Butte, Montana.

General Resumption of Work.—Widespread Activity in Exploration.—The East Side.—Vigorous Search for Copper.—Butte & London.—Amazon-Butte.—The Reins Copper Co.—British-Butte.—Settlement of the Wage Question.—Satisfactory Result.

Since the settlement of the wage question all development work at the mines and construction work have been resumed and between 2,000 and 3,000 more men are now employed than a month ago. Work on the improvements at the Washoe and Great Falls smelters has been recommenced. The Anaconda Co. is sinking the shafts of the Anaconda, High Ore, and Neversweat mines, and the Coalition Co. is sinking the Rarus and Tramway shafts and cross-cutting from the 2,200 of the Corra, and is making a connection between the Tramway and the Rarus shaft. The Coalition is also doing a lot of development work in the Rarus, Minnie Healey, Corra, and Alice mines. The Boston & Montana is engaged in building its great hoisting plant at the Leonard and is sinking several of its shafts, besides being engaged in a lot of development work in the Leonard, Colusa, Pennsylvania, Mountain View, and other mines. Clark is pushing development work in the Stewart and Original, and the Trenton is doing a lot of development and exploration work in the Gagnon mine, while the Parrot has resumed sinking.

There is increasing activity in that part of the Butte district known as the East Side; several new companies recently began operations and the line of shaft-sinking now extends for three miles north and south. Among the exploring companies at work are the Butte & Bacorn, which is sinking three shafts; the North Butte Extension Co., the Butte & London, the Butte Exploration, Colusa-Leonard Extension, Bullwhacker, Amazon Butte, Ida-Montana, Calumet & Butte, Butte & Summit Valley, and the Amalgamated, the last being engaged in sinking a shaft and exploring the Greenleaf claim near the property of the Butte Exploration Co. All of them are working with machinery capable of going to a depth of 1,000 to 2,000 ft. Some of them will go 1,500 ft. before attempting to explore the ground for copper ore. The shaft of the Butte & London has reached a depth of 900 ft., at which point a small vein was cut, but it is believed to be the vein seen several hundred feet higher. The shaft at present is in hard granite and the company has increased its bonus system by offering the men $50 per foot for every foot in excess of 70 ft. made during a month.

The Amazon-Butte Co. is the first company on the east side to strike shipping ore. From the Gaynor shaft lessees are sending 20 to 30 tons of ore per day, some of it assaying as high as 15% copper. The main shaft is down more than 300 ft. To the east of the main shaft is located the big fault-vein on which the Bullwhacker is working, and it is the belief of mining men that the east and west veins will run into the fault at a distance of several hundred feet east of the shaft, and that at the point of juncture immense bodies of high-grade sulphide ore will be found. East of the Amazon Butte some property is being developed by the Calumet & Butte Co. Its shaft is now down about 500 ft. Stringers and small veins have been cut. Not more than 300 ft. from the Calumet & Butte, the Ida-Montana Co. is sinking a shaft on the Ida claim, and has reached a depth of 250 ft., where a station is being made. Both companies are owned by Duluth men and there is talk of consolidating them.

The Reins Copper Co., which has been developing the Combination mine lying between the Leonard and the Pittsburgh & Montana ground, is approaching a self-sustaining basis, as it is now making regular shipments of ore. Last week two cars netted the company $3,600, and the week previous two cars brought $4,500. Ore is being mined from the 800 and 1,200-ft. levels. Cross-cutting is being done from the east end of the property north toward the Ella claim, recently purchased, upon which there is a developed vein. The cross-cut will be continued north through 400 ft. of Amalgamated ground into another small claim owned by the Reins Co., known as the Louise. The Reins has a large indebtedness, which will prevent the company from paying dividends for some time yet.——It is reported that the British Butte Co., which owns some ground several miles west of Butte in an undeveloped area, is preparing for the installation of a lot of machinery for the purpose of beginning exploration work.

The settlement of the wage scales for the miners and smeltermen of Butte, Anaconda, and Great Falls for a period of five years is one of the most important things accomplished in the interest of the mining industry in Montana in many years. Under the agreements reached between committees from the unions and John D. Ryan, managing director of the Amalgamated Copper Co., the miners will receive $4 per day on and after April 1 so long as the price of copper remains at or above 18c. per pound. The smeltermen will also receive an advance in wages so that the average paid at all the smelters will be about $3.50 per day. Last November, when the mining companies voluntarily granted the miners and smeltermen an increase of 25c. per day, the raise applied only to smeltermen, who had been receiving less than $3 per day, and therefore did not affect the skilled men at the smelters. It was to equalize wages that a re-adjustment was granted. When the miners, a month ago, announced their intention to vote on an amendment to their constitution making the permanent daily wage $4, they were notified by Mr. Ryan that the Amalgamated Co. would not pay the increase, and that while the company, at the present price of copper, could afford to pay it, it could not pay the $4 scale should copper again fall below 18c., unless the company should confine itself to mining only high-grade ore, which would not be good for the life of the company. Mr. Ryan said the aim of the Amalgamated Co. is gradually to grade the ore lower in average so that eventually ore carrying as low as one per cent copper could be mined at a profit. An intimation was made that, if the miners amended their constitution to make the wage-scale of $4 permanent, all the mines would be closed. The amendment was voted by a large majority and instantly about 3,000 men employed

in development and construction work were laid off by the Amalgamated. A committee from the Miners' Union asked Mr. Ryan not to take any radical action until the matter could again be submitted to the union. He suggested that if the miners would call a special meeting of the union, and hold it in a hall large enough so that the gathering would be representative, he would await the further action of the union. He suggested the appointment of a committee with authority to agree on a scale of wages for a term of years. A similar suggestion was made to the mill and smeltermen. The meetings were held and the committees appointed. Mr. Ryan met the committees and the five-year contracts were entered into and signed. Considering the difference in the character and hazardous nature of their work, it is considered that the difference of 50c. per day between the miners and smeltermen is equitable. The minor demands of the smaller unions, such as the engineers, machinists, and other trades employed by the mining companies, have not yet been adjusted, but they are not considered important and will be easily arranged. Following the general increase of wages granted by the mining companies last November, there was a general increase in the cost of the necessaries of life in Butte, and to prevent another similar result the miners, smeltermen, and mine managers will use their united influence. Warnings have been given that, if business men and dealers again raise the prices of commodities, the miners, with the approval of the mine managers, will establish a supply-house of their own. With the permanent settlement of the miners' and smeltermen's wage questions, it is expected that all other labor troubles in Butte will speedily adjust themselves, as the two big unions have announced their determination to withhold endorsement from the smaller unions, whose oft-repeated demands have been responsible for constant unrest.

Leadville, Colorado.

Zinc Output.—Manganese Ore.—The Morocco Company.—Mining on Ball Mtn.—Zinc Plant at Buena Vista.—Ore Under the Blue Limestone.—Progress in Big Evans Gulch.—The Yak Adit.

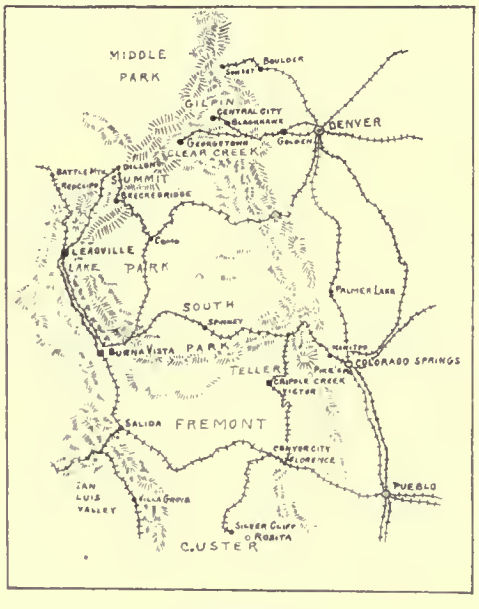
Local zinc producers are not seriously disturbed over the decision of the Board of Appraisers at New York, which, if adhered to by the higher courts, will admit zinc free of duty. The strong demand for this metal and the fact that Canadian and Mexican ores find a market through other channels, leaves little to be feared. Besides, zinc in the Leadville district has been for years a by-product that has been disposed of at a profit at a much lower price than the present quotations.

The failure of the Illinois Steel Works to renew its contracts for Leadville manganese has caused a notable falling off in the production of ore of that character. The above company is now drawing its supply from foreign sources, but the Colorado Fuel & Iron Co. consumes 15 carloads per month from the Morocco Mining Co., under an old contract. This tonnage has enabled the Morocco company to push developments to the west of Harrison Ave., and it now appears that this property will soon be producing an excellent grade of silver ore, instead of depending on their manganese alone for profit. It is rumored that certain steel works in the East will contract during the spring months for manganese in large quantities. There are a number of properties in the downtown district that are in a position to furnish large quantities of this ore. In fact, in former times, more than 60,000 tons annually has been produced by the district.

The lessees of the Sunday property on Ball Mtn. are at present sinking the shaft to cut the lower ore-horizon. The first large shipment since the property resumed operations came from the 125-ft. level. The shaft will be sunk another 200 ft. This property is a good example of the gold-belt mines, the ore being found directly in connection with the porphyry.

After driving an adit 180 ft., the manager of the Helen Gould property reports that a fissure vein was cut which promises to be fabulously rich. Development work in a limited way has been in progress on this property for several years.——The McCarty & Moore machine-shops have been given the contract to build all of the machinery, except the electrical, for the new zinc plant that is to be erected at Buena Vista. The plant will be operated under the Keunzer process and will draw its supply chiefly from Chaffee county mines.

Notwithstanding that some eminent geologists were formerly of the opinion that little ore could be expected below the blue limestone, the operators of the present day



A Part of Colorado.

realize that there is no significance to be attached to any particular limestone formation.

Limestones of any character in the productive areas of the district seem equally prolific, and the miner of today only requests limestone contacts with anything but granite. Quartzite and porphyry contacts are both good ore-horizons, with either blue (Carboniferous) limestone or white (Silurian) limestone, and as a matter of record, some of the most valuable discoveries of the past two years have been at the quartzite contacts.

Rapid progress is being made in the development work on the Boulder property in Big Evans gulch. This part of the camp of late years has experienced more difficulty from heavy flows of water than any other portion of equal area. Timothy Kyle, manager of the Boulder property, lately completed the installation of an efficient pumping and power-plant, with a boiler capacity of 285 h.p. Mr. Kyle sunk the old shaft on this property several years ago, when the last shots in sinking opened up an unusually strong water-course and stopped all operations until the present company undertook the work of development.——W. H. Covey and associates have done considerable work on the Hibschle shaft, between Seventeenth and Eighteenth streets, above Orange. A drift to the west at the 440-ft. level has encountered a substantial body of ore near the Elk fault, and 40 tons of ore are being sent to the smelter daily.——It is interesting to note in connection with the operations at the Yak adit, that an enormous amount of development work is in progress in advance of mining the ore. Thousands of feet of diamond-drilling is being done during the period of a single year

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE highest and broadest of the mountains and the chief part of the mass of the continents were lifted above the ocean mostly after the Cretaceous period.

SOLID METAL and rock, when under pressure, yield through molecular movement, and may thus become compressed, drawn out, flexed, and otherwise deformed.

A DRILL mounted upon a tripod is the combination commonly used for surface drilling, and even underground on the benches of railway tunnels, and often in stoping ores.

THE grander divisions of geological time are based, in a comprehensive way, on organic progress, independently of events connected with rock-making and disturbances of the crust.

THE term *vesicle*, as applied to a vapor-blown cavity in an igneous rock, has been put into another form in the word *lithophysa*, and applied especially to peculiar chambered cavities common in obsidian.

THE diamond-drill is a valuable apparatus for determining the nature of bridge foundations and the character of proposed canal or railway excavations, as well as in prospecting for valuable minerals.

HALLOYSITE is a hydrous silicate of alumina, like kaolinite, but amorphous and containing more water. It is a massive, clay-like or earthy mineral with a conchoidal fracture and showing little or no plasticity.

IN that portion of the United States formerly covered by the continental ice-sheet, there are occasional deposits of clay formed directly by the glacier. These are usually tough, dense, gritty clays, often containing many stones.

ON the amalgamating plates, the gold is caught earlier than the silver, since silver has less tendency to amalgamate than the gold, and hence the ratio of gold to silver in amalgam is less the farther the amalgam is from the battery.

IN some deposits of clay, the limonite or siderite collects around nuclei, such as pebbles or grains of sand, and grows into more or less symmetrical ball-like concretions, which are most abundant in the weathered portions of the clay.

IN a direct-current circuit the power in the circuit equals the product of the E. M. F. in volts and current strength in amperes, while in an alternating-current circuit the instantaneous power equals the product of the instantaneous values of current-strength and voltage.

IN the correlation of the rock-records, in view of the impossibility of determining true synchronism, Huxley proposed to designate by the term *homotaxial* those strata, in regions more or less widely separated, that have apparently the same relative position in the geological series

MANY rivers, especially in broad valleys, are bordered by a terrace or plain, there being sometimes two or more, extending like a series of shelves, or steps, up the valley-side. The lowest of these is often covered by the river during periods of high water, and is consequently termed the flood-plain.

THE leading idea in many magnetic separators is to secure a strong magnetic field by concentrating the lines of force as far as possible. This is done by placing the two poles of the magnet facing one another with a minimum air gap between them, and by beveling down the pole pieces at their ends.

PLASTICITY may be defined as the property which many bodies possess of changing form under pressure, without rupturing, which form they retain when the pressure ceases, it being understood that the amount of pressure required, and the degree of deformation possible, will vary with the material.

MERCURY TRAPS are pockets designed to catch amalgam and floured mercury that has drained off the plates. Incidentally, the traps always catch some heavy sulphides, and, although they do not have mercury put in them, yet the mercury soon accumulates, making them partake somewhat of the nature of mercury wells.

A STREAM of water can be thrown vertically 103 ft. and horizontally 96 ft., with a pressure of 100 lb. at the nozzle and 1⅛ in. diam. The nozzle will discharge 674 gal. of water per minute. With a higher pressure, equivalent to a higher head, the amount discharged and the distance to which the water may be thrown will be increased.

WHETHER a high-power or a low-power explosive is to be used in blasting, is dependent largely upon the use to which the rock is to be put, as well as upon the strength of the rock itself. Black powder, with its comparatively slow, heaving action, is used where the material is quite friable, as in mining coal or galena, or in excavating shale, hardpan, and similar material. A high-power explosive like dynamite is invariably used in tunnel-driving, shaft-sinking, and open-cut work in tough rock. It cannot be used for quarrying dimension stone, as it shatters the rock.

IN Blaine county, Idaho, is to be seen one of the most interesting occurrences of lava-flow that there is on this continent. Just south of the Lost River country, about 200 miles of what was an arid, sagebrush desert has been covered to a depth of from 20 to 600 ft. by a comparatively recent flow of black basalt, the age of which is estimated to be not over 150 years. So recent is it, that weathering influences have not had time to accomplish any surface alteration, and the rock stands as fresh and unchanged as when first erupted. The eruptions were of the quiet type, the lava welling up from central points, and flowing away on a gentle grade in all directions, but enough preliminary explosions and ejections occurred to build up a series of central craters, often 600 ft. high, forming an extremely rugged and interesting topography.

AN original location may be made upon vacant and unappropriated public mineral land at any hour of the day or night. As to such original location the law makes no inquiry as to the exact point of time at which it was initiated. Where, however, a re-location of a claim is attempted on the asserted ground of a forfeiture or abandonment of the original, the circumstances surrounding the re-location are proper subjects of inquiry. The Courts of California look upon 'midnight' locations of this character with suspicion as evidencing an intention to secure a right surreptiously. The original locator has the right to resume work at the usual hour for labor in the morning, and such resumption, if made, would defeat a location made secretly and surreptiously at an earlier hour in the morning. This is as far as the decisions have gone.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Sampling and Assaying.

The Editor:

Sir—I have read with considerable interest the letter of 'Enquirer' on this subject, published in the MINING AND SCIENTIFIC PRESS of March 16.

In my opinion, a man may be a first-class assayer on all ordinary gold ores, and yet get away off on some ore that appears simple, and requires either an unusual quantity of some special flux, or element, to free the gold from its combination in the ore.

In substantiation of this statement I will tell of one of my failures; which will read like a fairy story. A number of years ago, I accepted the position of assayer and mill-foreman at the Golden Gate mine, in Tuolumne county. The Golden Gate was strictly a concentrating proposition, yielding less than 2½% of its gold by amalgamation on the plates; and carried its value chiefly as telluride of gold associated with low-grade iron pyrite. The value was saved in the form of concentrate from the Frue vanners and a large canvas plant, to be treated by chlorination in the company's works at the mine.

Shortly before I began work the company had been repairing the roasting furnace at the chlorination plant, and had removed about a ton or so of common red brick from the floor of the furnace and substituted a floor of fire-brick. As the superintendent was about to make a shipment of some slag and clinker to the smelter, he told me to take a sample of the old brick, and see if it was rich enough to include in the shipment. I broke up a lot of the old brick and mortar, and got as fair a sample of it as I could without having it crushed; this I took to the assay-office, and crushed a sample through a 120-mesh sieve; I fluxed a couple of one-half A. T. charges with my usual flux, consisting of a heaping tea-spoon of litharge, two of soda, and flour, for about a 20-gram button, with a spoon of borax as a cover. The assays fused well, and gave a good clean fluid slag and nice soft lead buttons; these I cupeled, and was surprised to find that I had not even a trace of gold on the cupels; although I had previously tested the sample with a pan, and found a nice string of fine gold. Thinking that perhaps the bricks might contain tellurium, and needed an excess of litharge, I ran a couple of scorification assays, and cupeled them with the same result, of nothing. I then made another crucible assay; taking only one-fifth of an A. T. with my usual charge of flux. These buttons when cupeled and the gold parted gave me a fairly good check of $105 per ton. Being crowded with other work at that time I reported the value at that figure; and filed the sample away, to be kept one year, as was the practice at the mine.

About two years later, as I was discarding my old samples I came across the brick sample; and as I had more leisure, I repeated my one-half A. T. assay with the same result of not a visible trace. I examined the cupels carefully with a magnifying glass, but could not find a visible trace of gold, or any unusual appearance about them. I took and ground them up and fluxed them with an excess of borax, silica, and litharge, with flour, for a button. The result of this assay was two gold beads ranging in value between $120 and $140, and as near as I remember giving an average value of about $130. I then took the two cupels and combined them for a second assay. These gave me an additional value of about $20 per ton. An assay on the third set of cupels yielded a further recovery of nearly $5. Making the recovered value of the ore nearly $160 per ton.

I reserved the balance of the sample, intending to send it to some good chemist, who would make an analysis on the ore in the interest of science. A friend of mine recommended a well known assayer in San Francisco, and I sent the sample to him, telling him of my tests. He never acknowledged the receipt of the sample, or would reply to any of my letters enquiring about his results.

If any of your readers who live near Sonora are interested in the subject I would be pleased to have them obtain permission of the present owners of the plant and procure another sample and have it analyzed, publishing the result of the tests in the MINING AND SCIENTIFIC PRESS.

I think that perhaps a few little chips taken from any of the remaining red brick in the floor of the furnace, just back of the substituted fire-brick, might contain some of the same elements.

WILTON E. DARROW.

Sutter Creek, Cal., March 27.

Mr. Schurman's Philosophy.

The Editor:

Sir—Referring to an article under 'By the Way' in your issue of February 9, I would say that the astonishing socialism and unscience of Mr. Schurman's argument leaves one to wonder of what intellectual material presidents of colleges are made. In 1875 Professor Duhring of Berlin University published to the world a plan of socialism, which might have been the target for some of Mr. Schurman's criticisms, but this was utterly demolished by Frederick Engels in his masterly work, entitled 'Socialism, Utopian and Scientific.' Schurman's address does not show the slightest indication of acquaintance with evolution in the progress of animal or human life. He begins by approving as wise the quite anarchistic principle of *laissez faire*, deplores despotism, fears over-government, even for the positive promotion of the common interests of all members of society, and chides people for noticing the concentrating processes by which, in true gold-mill parlance, a few men get the richest concentrate, and the many workers the most barren tailing. All these remarks fail to touch scientific socialism at all. This science leads us along the course of evolution of racial customs in production and distribution of wealth, determining production to be a social factor, and bases political economy upon social interests, which require the elimination of non-producers from social consideration. How this works out in a perfect diagnosis of every good and evil of present-day industrialism, and the trend toward collectivism, like a great tide, not a cheap man-made bureaucratic plan, but an inevitable development of the fittest, is finely shown in Engels' work. If you cannot get it on the Coast, I will mail it to any of your readers for 15 cents. Schurman's attitude is that of a timid empiric. He does not know what he is dealing with, and if his fears, lest the people cannot take care of themselves without spoilsmen and geniuses whose cleverness runs only to disproportionate holdings, were to have governed the history even of the beggarly past, there would never have been any human progress.

The very weakness and hesitancy of such 'stand-patters' tell that they belong to a failing order. The resolute people who believe in carrying the principles that have won the mastery in other fields of science into the department of sociology will not be denied. I find that these proletarians have more science than the graduates of our bourgeois scientific schools, that they are full of energy and enthusiasm, where their opponents are

tame and sluggish, so that the forces of popular advance are sure to push them back.

To formulate academic objections to socialism will not stop those whose best word is action, and whose only use for objections is to overcome them. I myself feel twenty-five years younger since my interest was aroused to work in the great laboratory of social phenomena. And as for the class struggle, President Schurman's position reminds me of that of Balaam when he was asked by the prince of Balak to prophesy against the energetic new people who were threatening the dominion of Canaan. But there seems this difference, that Balaam had to prophesy the impending truth, and told the Canaanite prince "what this people will do to thy people in the latter days." Science is a greater prophet than Balaam, and she declares with unmistakable clearness just why no bribes of accumulated wealth, nor enchantments of vested privilege will avail to stay the proletarian tide.

CHARLES H. FITCH.

124 So. Grove Ave., Oak Park, Ill., March 26.

[We disagree heartily with the tone of this communication; but it appears just to publish it as a retort to the extract from Mr. Schurman's address.—Editor.]

Sampling and Assaying.

The Editor:

Sir—With reference to the experience of 'Enquirer,' it appears evident that the apparent discrepancies are due to one or more of the following reasons:

(a) Faulty sampling.
(b) Faulty preparation of samples.
(c) Faulty assaying.

(a) Faulty sampling: This probably accounts for the discrepancies between the results of the various 'experts.'

(b) Faulty preparation of samples: Unless, as you suggest in your editorial note, the ore has been put through a 100-mesh screen before dividing it between the different assayers, it is possible that the gold was distributed unevenly, thus explaining the more interesting discrepancies in the returns from the same sample.

(c) Faulty assaying: When samples have been assayed by an inexperienced man we have seen widely different returns from an ore containing a heavy proportion of pyrite. These differences have been due to the misuse of methods that require care. In the 'nitre' method there is sometimes a loss due to violent action in the crucible. In the 'iron nail' method there is occasionally a loss that can be traced to the formation of a brittle matte, containing gold and silver, which becomes scattered in the process of cleaning the lead button. Errors due to these two causes may be laid to carelessness, and do not prove that "assayers of established reputation" failed to get all the gold; they rather prove that the reputations of the assayers are not yet established for anything but cheap work.

Admitting that the facts are as stated by 'Enquirer,' it is natural to ask why the mill-returns were not accepted as controlling evidence of the value of the ore. The product of the mill is, after all, the crucial test. A point seldom considered by optimistic promoters of a mining sale, is that capital is not interested in a low-grade ore so complex that its precious contents cannot be recovered by the simple process of fire-assaying, since the ultimate recovery of 'dividends' from a sulphide ore depends in the end on the smelter man, who makes his settlement by fire-assay, and who has to employ this same process on a larger scale to reimburse himself.

There may be gold in sea-water and black sands. There is undoubtedly a great deal of silicon, aluminum, and iron distributed on the streets of San Francisco in the form of mud, but it lies untouched.

INVESTIGATOR.

San Francisco, March 26.

Pachuca.

The Editor:

Sir—In writing just twelve months ago in the columns of the MINING AND SCIENTIFIC PRESS an article on the Pachuca district, I drew a comparison of the valuation of three of the leading mines of the Pachuca and El Oro districts.

In that article I pointed out the lack of uniformity of valuation in the two districts, which feature it was surmised was mainly owing to the different ownership—the Pachuca mines being locally owned, while El Oro mines were foreign-owned. It was also pointed out that, if the latter group were justified in their valuation, that of the Pachuca mines was unduly low, and it was inferred that they were capable of a considerable increase of output and appraisement of value.

Since the writing of that article, much has happened, especially at Pachuca, and it may be of interest to note the comparative standing today.

	March, 1906. Valuation in pesos.	March, 1907. Valuation from shares and option prices.
PACHUCA.		
La Blanca	6,125,000	10,000,000
Santa Gertrudis	5,350,400	9,000,000
San Rafael	5,804,800	7,008,000
Total	17,280,200	26,008,000
EL ORO.		
El Oro	13,500,000	12,960,000
Esperanza	20,475,000	12,285,000
Dos Estrellas	30,000,000	21,000,000
Total	63,975,000	46,245,000

The ratio of valuation was as 1 to 4 in March, 1906.
The ratio of valuation is as 1 to 2, or less, in March, 1907.

To account for this considerable difference, it is to be noted that while the Pachuca district has risen considerably, judged by the valuation of the investing public, El Oro has shrunk materially. This is by no means discreditable to the latter—indeed, the record for the twelve months has been unsurpassed in the history of the camp, and placed it as the second largest producer on the American continent. During this period the Esperanza mine has maintained a monthly output of from $600,000 to $700,000, or an output of over a ton of pure gold per month for one year—a feat that has never been equalled in the history of gold mining by any individual mine.

If the purpose of mining is to extract the ore and put the bullion into circulation in the shortest possible time, then the policy of the Esperanza is correct, and in marked contrast to Mexican mining in the past, where the future was as much considered as the present. Consequently, the shrinkage of El Oro camp is occasioned by the rapid extraction of the ore, which governs the valuation of the mines. They are living their lives and living them merrily.

Be this as it may, this camp is but utilized for purposes of comparative valuation, and nothing more.

Returning to the Pachuca district, no one would venture to state that the considerable appraisement is the direct result of increase in ore reserves, which alone really governs the value of any mine; but it is rather the increased appreciation of these mines. In other words, the ywere unduly low in market valuation twelve months ago, which my article endeavored to point out. Now that fresh capital is being introduced and fresh interest awakened, the possibilities of this old—yet still young—camp are being recognized, and the probability is that, with the advent of further capital and cheap power,

Pachuca is yet in the initial stages of an upward movement.

Reviewing recent history, we note that the Real del Monte was the first to change hands at the beginning of 1906. Then an option was given on La Blanca, followed by an offer on the Santa Gertrudis group, which offer was apparently not satisfying to the shareholders, although a material advance on current prices. It is possible the San Rafael group may follow next—at all events, in sympathy with the forward movement, this mine has considerably increased in the public estimation during the period under review, and, as a matter of fact, in dividends on capital invested at the current prices during this period, it has far and away been the best paying mine in the district; although, of course, La Blanca has yielded the greater aggregate returns.

This brief retrospect is chiefly of interest as showing what a short twelve months is capable of producing in Mexico of today.

H. E. WEST.

Akmolinsk, Siberia, March 1.

[Mr. West's statement as to the output of the Esperanza is too high, for realization on the ore produced has been seriously hindered by shortage of railroad cars. But his remarks are interesting, and emphasize the importance of Pachuca as a mining district.—Editor.]

Mining in Siberia.

The Editor:

Sir—I note frequent references of late, in your London correspondent's letters, to the new Siberian mining ventures, in which a considerable amount of financial interest is manifested in London. Having had former experience in Siberia and in European Russia I feel qualified to express an opinion concerning that field as a future mining province. In the first place, it is rather a waste of space in an American mining paper to print news of so remote a country. To the American professional man operations in the great gravel mines of Siberia possess a certain amount of interest. The well-established practice there is, however, pretty generally known. On the other hand, to the American investor news of Siberia is like news from the Mountains of the Moon, and excites an equal amount of practical interest. Mining gold in Nevada, and copper in Montana, Arizona, and Michigan are at present sufficiently profitable enterprises. The American will not follow the Londoner in Siberian investments. There is no reason why he should, as there is plenty of undeveloped metalliferous territory nearer home; for example, Arizona, Nevada, Mexico, and Alaska. Why then should space be consumed in accounts of London board meetings when the only business discussed is the formation of a Siberian company or its troubles?

So far as Siberian enterprises themselves are concerned, it is rather surprising to see the utter ignorance which the average Londoner has of the country into which he is putting his money. Quartz-mining properties which have been thrown from pillar to post on the St. Petersburg and Paris markets for the past ten years are now seen masquerading under other names in London, apparently very well received.

There seems to be no discrimination in the investments; one hears of really meritorious East Siberian gravel properties on the same footing as the poor stringer-lead quartz mines of the Khirgese steppes and southern Ural. The two parts of Siberia are just as nearly comparable in point of richness and situation as a good drift mine in California and a quartz mine in northern Georgia.

There seems to be in many cases some anxiety as to the validity of Russian titles, and I would say that in the case of Russian mining 'concessions' such inquiries cannot be too carefully made. On the other hand, where Russian mining 'claims' are located or bought outright, no title in any country could be sounder. I have personally located and patented mining claims in Russia, as an American citizen. In the present Siberian flurry one hears little inquiry into the labor question, which seems rather important in any mining district. There are many kinds of labor in Siberia and the Urals, and eventually a good class of mining labor will be developed. This labor must be nursed, however, and the process cannot be undertaken through the medium of interpreters.

Siberia needs no apology and no defense. That it contains one of the world's greatest stores of accessible gold I have previously stated, and still maintain. The American engineer today who acquires a working knowledge of the Russian language will add a valuable asset to his equipment.

C. W. PURINGTON.

Munich, March 25.

Standardization.

The Editor:

Sir—In your issue of March 23, the recommendations of the Institution of Mining and Metallurgy, regarding the adoption of certain standards of weights and measures, are given and discussed. Doubtless all members of the profession would profit from the general use of these standards and will stand ready to adopt them wherever practicable.

The suggestion, with which your article ends, regarding the difficulty of properly describing or differentiating United States and Mexican currency, however, does not remove the difficulty complained of, except in the use of spoken and written words, where 'dollar' and 'peso' are so distinct as to allow of no possibility of misunderstanding, if regularly used to differentiate the two currencies. The main difficulty, however, is not in words, but in signs and figures. The dollar and *peso* are both indicated, by Mexicans as well as by Americans, by the '$' sign, so that it would be imperative to differentiate the figures by some other sign, or to continue in the present clumsy method of writing 'Mex.' or 'U. S.' after the figures, which, unfortunately, leads to the misunderstandings complained of.

To write 'dollar' or 'peso' in front of the figures is too clumsy to think of and has no advantage over writing 'Mex.' or 'U. S.' after the figures; and to forge a new sign for either coin, that the business world could be induced generally to adopt, is manifestly impossible.

The present writer, therefore, sees no better plan than to be more careful, *when using figures*, to write thus: $7.80 U. S. or $7.80 Mex., for which custom already gives us warrant.

The suggestion made a year ago by the MINING AND SCIENTIFIC PRESS, and repeated in your recent issue, that the words 'dollar' and 'peso' should be used respectively to distinguish between American and Mexican currency, has already borne some fruit, as evidenced by the greater care taken by many in the proper use of the two words, and it is still further to be urged that, in using the word 'dollar,' only American currency should be referred to, and that the word 'peso' only (and not dollar) should be used in referring to Mexican currency.

FRANK LONGMAID.

Boeme, Texas, April 4.

AN ABRAS, or orebody, so called by Mexican miners, is a small stringer extending outward from the main orebody, along a small joint or fissure, which, when met at surface, is most always followed downward, finally opening out into a pipe or chimney.

A Filing System For Mining Engineers.

Written for the MINING AND SCIENTIFIC PRESS
By WALTER S. BROWN.

The average mining engineer is much in need of a systematic and convenient method whereby he can instantly put his hand upon any letter, any piece of technical information, or any pamphlet or catalogue that is in his office. The system described herewith will answer these requirements and, once started, can be kept up with but little expenditure either of time or of money.

The system naturally divides itself into four parts, namely, correspondence, technical information, catalogues, and miscellaneous. Each division has its own card-index and filing-drawer.

Filing cabinets are of many styles and many makes, but there is no question that the vertical system is the best one. This system enables one instantly to place any letter, invoice, catalogue, document, or memorandum; or any collection of letters or papers about any given subject. It does not mix things but keeps together papers that ought to be together, in such a manner that they are instantly accessible. It is as easy to operate with a great many papers as with a few. For the initial unit the five-drawer combination cabinet, consisting of three filing-drawers and two card-drawers, is best. Each card-drawer has two compartments each of which will hold 2,000 cards, thus giving a total card capacity of 8,000 cards. Each filing-drawer will accommodate about 4,000 letters with their folders or the catalogues from about 70 firms, so that the first unit will be sufficient until the engineer has filed away 4,000 letters, 4,000 sheets of information or their equivalent in sketches, photographs, small drawings, etc , and the catalogues from about 70 firms. When this stage is reached, an additional unit containing four filing-drawers, can be purchased for about $20, and so on indefinitely. At a small additional cost the units can be fitted with a lock that will act upon all the drawers at one operation. The cards and folders should be of four different colors, white for correspondence, salmon for information, blue for catalogues, and buff for miscellaneous. The cards should be of 4 by 6 in. size. In case the numeric system of indexing is adopted, the folders should be numbered by the manufacturer, but the cards should be numbered by the engineer. A numbering machine costs about $12, but it is of great assistance, especially in numbering catalogues.

There are three principal systems of indexing, namely, the numeric, the alphabetic, and the geographic. Of these the numeric is by far the most accurate, the quickest, and in every way the most satisfactory. In the card-index it is necessarily the same as the alphabetic, but in every other respect it is far superior. It obviates the chances for guesswork or error in placing any paper, for there can be but one proper position for a folder with a number on it, while if the folder is designated by a name, it takes more time to find its proper position in the drawer, as this position is frequently determined by the fourth or fifth letter in the first word. Moreover, there is always the difficulty of knowing which should be the index-word. For example, should it be 'Transmission Rope' or 'Rope, Transmission;' should it be 'Hoisting Machinery' or 'Machinery, Hoisting'? The geographic system is applicable in special cases only.

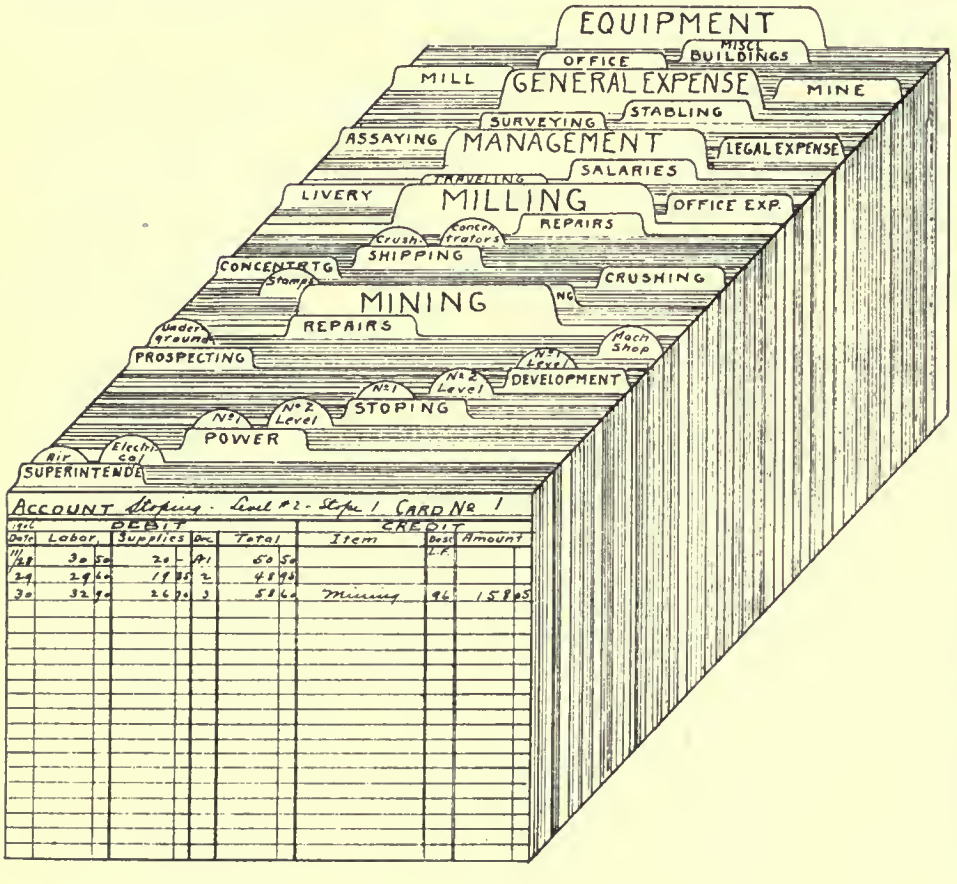


Fig. 1.

In filing correspondence, each correspondent is given a white card and a number. The card should have on it, the name and address of the correspondent, his filing number in the upper right-hand corner, a record of letters sent and received, and any other information the engineer may desire. In the correspondence-drawer, or drawers as the case may be, is a white folder with the same number on it that is on the card and in this folder are placed all letters to and from this correspondent, each letter or paper having on it the correspondent's number, the last letter being in front. To look up a letter from this person it is first necessary to get his number from the index and then simply find the correspondence-folder bearing that number. If it is desired, a card-ledger may be kept in the correspondence-index without interfering in any way with the correspondence.

The file for technical information is conducted in the same manner, except that cross-indexing is necessary. For example, suppose the engineer has the data showing the results of some tests on chrome-steel roll-shells. Then the heading of the index-card will read: 'Roll Shells, Tests on Chrome Steel,' followed by the number of the folder in which the information is to be placed. Then on another card will appear, as a heading: 'Materials,' and under this: 'Tests on Chrome Steel Roll Shells' followed by the number of the folder. On still another card will appear: 'Steels, Special,' and under this the same thing that is under 'Materials,' and so on, the more systematic and complete being the cross-indexing, the more valuable the index. Often it is desirable to put several bits of

memoranda in the same folder as, for example, all the information concerning a certain mill. But it should always be borne in mind that, unless properly cross-indexed, a certain memorandum may be filed away in a folder and completely lost unless the searcher takes the time to finger over the entire index.

In the catalogue file the index-card has, for a heading,

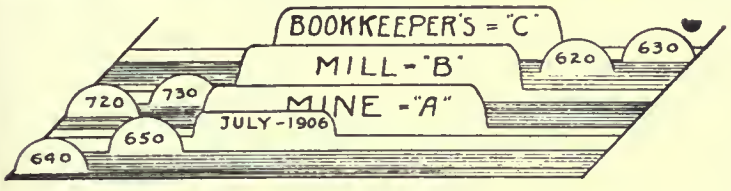

Fig. 2.

the name of the firm and its filing number. Then underneath comes the home address of the firm and the address of its nearest branch office or the name and address of the agent of the firm. Below this comes a list of what the firm handles and this may be followed by discounts on certain machines, terms, etc. as the inclination of the engineer may lead him. In the catalogue file too much stress cannot be placed on the necessity for thorough cross-indexing. The cross-index cards will have such headings as: 'Pumps,' 'Crushers,' 'Grinders,' 'Engines, Gas,' 'Engines, Steam,' 'Jigs,' 'Dredges,' etc. Large book-size catalogues are placed in the bookcase and a reference made to them on the firm's index-card.

The miscellaneous file will be arranged according to the dictates of the engineer. It may contain a town-index guide for one or more States, these guide-cards being obtainable for all the States, as well as British Columbia, Manitoba, New Brunswick, Nova Scotia, Ontario, Prince Edward Island, and Quebec, with a card for each town having a population of 200 or over. Or it may be a temporary index and contain a number of references on some important piece of work that the engineer may have in hand. Maps, especially those of the United States Geological Survey, may be kept in special map units and indexed either in the information index or in the miscellaneous index.

An engineer is, from his training and work, supposed to be precise and accurate, and it would therefore seem that he should be at least as methodical in his profession as the average business man. But how many engineers are there who can instantly find that scrap of information which they put away somewhere a few months ago with the vague idea that they might need it and which now they are so anxious to obtain?

Sampling of Ore.

Ores usually reach the reduction works or smelters direct from the mines, ranging in size from 12 to 16-in. cubes down to the smallest particles, and from 1 to 2% in hard ore up to, in some cases, from 20 to 30% moisture in ores containing clay or talc. As these ores are purchased outright from the mining companies the first process of treatment is weighing and sampling to determine the dry weight and the value of the ore. Sampling and weighing, thorough and correct, should, however, be done at all mills, more especially as automatic sampling has now been so far perfected that the exact value of the ore can be determined for a few cents per ton. Consequently there is really no valid excuse for any mill, however unpretentious, not having correct sampling devices to determine, without peradventure, the value of the ore before treatment, as well as careful and thorough sampling device for the tailing. Tailing samples alone will not show the losses in metallurgical works where there are many means of leakage besides the final one. With proper weighing and sampling of the crude ore the amount and value of the precious metals entering the works is determined; this with the bullion shipments and the loss in the tailing will soon show up other possible losses, and enable the metallurgist in charge to trace them and remedy the defects. I could give some extraordinary cases of losses, extending over years, and involving immense sums in the aggregate, that with proper sampling would have been detected in a month.—Philip Argall.

The Cost of Labor on the Rand.

Written for the MINING AND SCIENTIFIC PRESS
By EDGAR P. RATHBONE.

Now that the result of the elections for the Transvaal Legislative Assembly is known and a ministry has been selected, I think it will be generally agreed that as far as concerns the gold mining industry of the Rand, it is better to have a sympathetic government behind it than the reverse. The latter was unquestionably the case when the Transvaal was a Crown Colony with a Liberal and Radical Parliament. Had the Progressive party, composed largely of the representatives of what is known as the 'mining groups' on the Rand, won the day, there can be little doubt that it would very shortly have found itself in conflict with the British Government when it came to deal with the various unskilled labor problems, connected with the employment of Kaffirs, Chinese, and one might add Indian coolies, seeing that all of them raise Imperial issues.

Thus, if a certain native policy were to be pursued it might result in a native war, requiring the assistance of Imperial troops for which British taxpayers would have to pay, while if another Chinese ordinance were to be passed by the Transvaal Government, the Imperial Government might in some way bring pressure to bear upon China, and if it is sought to stop the inflow of cheap Indian coolie labor, in the guise of British subjects, it might be necessary to interfere.

The Imperial Government has, however, been directly instrumental in placing the Het Volk party in power and at the present time the ex-general Louis Botha, Premier of the Transvaal, is to attend a conference of Colonial Premiers at the direct invitation of the Imperial Government, on which occasion he will, as he deserves, receive much attention.

Louis Botha, however, represents a large portion of his countrymen that understand how to deal with natives from a long and bitter experience far better than a ministry chosen from the Progressive party could possibly have hoped to do. Botha, as a sensible man, fully appreciates the fact that the Boer interest, which is largely agricultural or pastoral, depends upon the success of the mining industry, and he is therefore certain not only to do nothing to hurt it, but to do everything to help it.

The world's supply of gold depends very largely upon the Rand goldfields and, consequently, it is not the Boer farm-owner alone, who will look to Botha and his ministry to help them forward. Roughly speaking, gold, to the value of $125,000,000, is being taken out of the Rand mines annually; out of this $32,000,000 is absorbed by about 15,000 white skilled laborers, many of whom are miners, who remit large sums monthly for the maintenance of their families resident outside the Transvaal. Another twelve to fifteen millions is absorbed by some 80,000 to 90,000 natives, fully two-thirds of whom are also resident outside the Transvaal, mainly in Portuguese territory. Finally $6,250,000 is paid annually for 40,000 to 50,000 imported indentured Chinese coolies; this also must be largely expended outside the Transvaal. From this it will be seen that out of the total value of $125,000,000 representing the gold extracted from the mines in one year, fifty is paid away in wages for skilled and unskilled labor. Finally, allowance must be made for the cost of the stores, such as coal, explosives, timber, candles, native and Chinese food, new machinery, buildings, etc. A recent estimate showed that another $45,000,000 goes in this direction. Exactly what portion of this annual value of gold finds its way into shareholders' pockets, it is difficult to say, as frequently, the declared dividends have been derived largely from market operations and shares.

Any real appreciable reduction in the cost of mining can certainly not be looked for in connection with greatly improved processes for the extraction of the gold, nor from any mechanical improvements except they be carried out underground in connection with labor-saving appliances, such as, improved forms of rock-drilling machines and mechanical transport for the haulage of the ore to the shaft. Even these economic factors are insignificant as compared to a direct reduction in wages. On the one hand we find some 15,000 skilled laborers absorbing $32,500,000 while $20,000,000 is distributed for the payment of nearly nine times as many unskilled laborers, that is Kaffirs and coolies!

The unmarried skilled laborer who can live 'the simple life' on the Rand goldfields, can do so for about $50 to $60 per month, which includes his board, lodging, clothing, and a very small amount of luxuries; while the married man, with a small family, would require nearly double this amount. Roughly speaking, the ordinary skilled laborer is paid $5 per day, so that as an unmarried man it is evident that there is not much of a margin to put by for the inevitable 'rainy day.' The cost of living has of late years been considerably reduced, but it is evident that far larger reductions must be made before it will be possible to greatly reduce the account for white skilled labor.

The Kaffir and coolie laborers stand in a far more enviable position, although only paid $15 to $20 per month as against the white man's $125 or $150, seeing that he is not required to pay for food or lodging, while his clothing bill is scandalously low. In the case of the Kaffir also his wife, and even his children, help frequently to keep him, and not he to keep them.

In order to make many of the Rand gold mines pay dividends where they are not now doing so, it is essential that one of several things should happen.

1. The average value of the ore mined must increase.
2. The companies must be re-constructed on a different basis.
3. The cost of living for the white skilled laborer must be so reduced as to fairly permit of a reduction in wage.

There is no reason whatever to anticipate either an increase or decrease in the average richness of the gold-bearing rock; in fact, all evidence goes to prove that it will always remain about as it has done in past years, though naturally improved methods in mining and sorting the ore may result in raising the assay-value of the ore sent to the mill.

A hundred million pounds sterling, or $500,000,000 has already been taken off the capitalized value of the Rand gold mines by the continued decrease in stock quotations, so that should still further reductions have to be made, it will be a disagreeable and unpopular process.

The cost of living will undoubtedly be gradually reduced, but taking into account the distance of the Rand goldfields from the coast, and the somewhat inferior nature of the country for agricultural purposes, until much more is accomplished in the way of irrigation, it is certain to be a slow process.

AS THE initial step in the investigation of black sands from placer mines, the Geological Survey sent a circular letter to the placer miners of the United States, requesting them to send by mail samples, weighing four pounds or less, of the heavy-sand residues left in their sluice-boxes. Over 2,000 samples were sent in from 34 States and Territories, and from British Columbia, Mexico, and America.

The Washoe Smelter.

*The Washoe smelter is situated about two miles east of Anaconda. The site includes about 240 acres, and peculiarly adapts itself in topography to the efficient handling of material. By reason of its being on a hillside it is possible to make the level of delivery of the product of one building the level of the charge-floor of the next.

The ore treated comes principally from the Butte district, and is hauled by the Butte, Anaconda & Pacific Railway, a distance of 28 miles, in trains of fifty 50-ton bottom-dump cars to the railroad yards at East Anaconda. At this point these trains are split up according to their destination, that is, as to whether they go to the concentrator and sampling mill ore-bins, or to the storage-bins. In each case they are made up into trains of eight or sixteen cars, according to the size of engine to be used, and are carefully weighed before delivery to their respective bins.

The concentrator bins are of wood and steel construction and are divided as follows: Eight second-class ore-

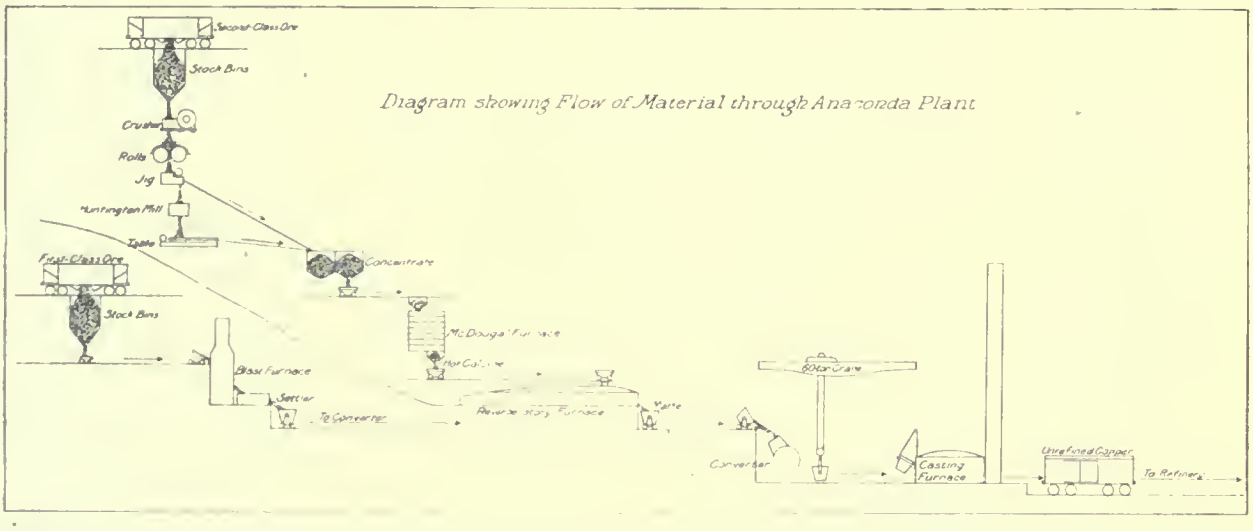

Diagram showing Flow of Material through Anaconda Plant

storage bins having a capacity of 1,250 tons each; thirteen sample ore-bins of 200 tons capacity each, and one coal-bin of 2,500 tons capacity.

The sampling mill is of wood construction throughout, and is 40 by 60 ft. and six stories high. It consists of two complete units, each unit having a capacity of 1,800 tons in 24 hours.

The ore to be sampled is taken from the sample-bins by an electric locomotive and dropped into bins feeding the crushers. The discharge of these crushers is elevated to the top of the building by means of bucket-elevators. The stream of ore is cut four times by Brunton automatic samplers, removing one-fifth of the amount each time and discarding four-fifths; the final result is 3.2 lb. for each ton of ore crushed.

The discard from the sampling machines is elevated and dumped into concentrator bins, or if it is first-class ore, it is sent to the storage-bins at the blast-furnaces. The final sample is quartered by a Brunton quartering shovel, the resulting sample dried on a steam-drier, ground in an Engelhardt sample-grinder, bucked so as to pass through a 100-mesh sieve, and made into three separate sample packages, one of which goes to the laboratory for analysis, one to the owner of the ore, and one is filed away for use in case of dispute.

The concentrator consists of two steel and wood buildings, each being 255 by 350 ft., and containing four complete units, or eight in all. Each unit is equipped with the same kind of machinery, and will handle 1,100 tons of ore in 24 hours. The equipment of one section is as follows:

1	12 by 24-in. Blake crusher.
2	7 by 10-in. Blake crushers.
6	Coarse concentrate Hartz jigs.
1	Set of 15 by 42-in. coarse rolls.
1	Set of 15 by 42-in. fine rolls.
36	Fine jigs (Evans patent).
1	Set of 15 by 42-in. middling rolls.
18	Middling jigs (Evans patent).
3	6-ft. Huntington mills.
18	Fine finishing jigs (Evans patent).
33	Wilfley tables.

Besides a large number of classifiers, settling tanks, de-watering tanks, elevators, and trommels of various sizes. A system of launders carries the concentrate to the settling tanks at the foot of the concentrator building.

The tank house is a frame building 70 by 670 ft. and contains nine settling-tanks for each unit. These tanks are 19 by 19 by 15 ft. high, each having a capacity of 120 tons of concentrate. These nine tanks are divided as follows: Six for first settlement of the concentrate, and three for second settlement of the concentrate, or, in other words, for settling the overflow of the first settling-tanks; the overflow from the second settling-tanks goes to three large tanks common to all units in that half of the mill; the overflow from these tanks going to the slime pond with the slime water from all the settling-tanks and Wilfley tables. The concentrate caught in the first settling-tanks is called 'fine concentrates;' that of the second settling-tanks is called 'second settlement concentrates,' and that of the third settling-tanks is termed 'tank slum.' The first two products are treated in the roaster building, the third at the briquette plant.

The slime ponds are situated in the valley below the works. There are six ponds of different sizes, but averaging about 300 by 630 ft., and the slime-water containing the greater metal values coming from the concentrator, goes to these ponds for settlement. When a pond is full, the water is diverted to an empty pond, and as much water drained off from the full pond as possible. The pond is then excavated by one of two Lidgerwood traveling cableways, each having a bucket capacity of five tons.

The slime is piled outside of the pond and allowed to drain and dry, and from these piles it is taken by cableway and dropped into a hopper on trucks, from which it runs into the railroad-cars beneath and is taken to storage-bins for use at the briquette plant. The slime-water containing the least values is used for condensing

*Abstract from a description prepared by the members of the Anaconda Copper Mining Co.'s staff.

purposes, and for sluicing slag at the reverberatories and blast-furnaces.

The settling-tanks containing 'fine' and 'second settlement concentrates' are emptied from the bottom, after draining, into the cars of the local tramming system and transported to the charge-floor of the calcine building, the material being weighed and sampled before dumping. It is the practice at this plant to weigh and sample the material entering and leaving every building, so that an accurate check is kept on the work of each department.

The roaster building is of steel construction throughout and is 96 by 412 ft. It contains 64 McDougal calcining furnaces of the Evans-Klepetko type. These furnaces have six hearths, 16 ft. diam., and are 18 ft. high; they have revolving water-cooled shafts and arms, driven by suitable gearing from the top. The rabbles are so set as to move the material from circumference to centre and the reverse, on alternate hearths until it finally drops into the calcine-hoppers immediately over the tracks of the local tramming system for transportation to the charge-floor of the reverberatory building. No fuel is used other than the sulphur in the concentrate, the burning of which furnishes sufficient heat to do the calcining, except on occasions when the furnace is not hot enough to ignite the sulphur, at which times fine coal is fed. The gases are taken through brick flues into large brick and steel dust-chambers, where a large proportion of the flue-dust is settled. This dust-chamber is so arranged that the bottom is a series of hoppers, so that the entire contents of the chamber can be drawn out into cars and sent directly to the reverberatory furnaces for smelting.

The material that sticks to the rabble arms, centre shaft, etc., called 'barrings,' is removed and sent to the blast-furnaces. Fine limestone and the screening from first-class ore in sufficient quantities to produce the slag desired in the reverberatories are charged with the fine concentrate through the feed-hoppers of the roaster for the purpose of getting an intimate mixture. Each furnace is capable of handling 45 tons of material in 24 hours.

The reverberatory plant consists of two steel buildings each 183 by 225 ft., each containing four coal-fired furnaces, the hearth dimensions of which are 19 ft. wide and from 102 to 116 ft. long, with a grate area of 8 by 16 ft. and a smelting capacity of 300 tons per 24 hours, on natural draft.

The fuel used is Diamondville coal, shipped from the mines in Wyoming, owned by the Washoe Copper Co. The coal is dumped into hoppers that have four points of discharge directly over the fire-box. It is the custom here to charge the furnaces from the first two hoppers next to the bridge-wall of the furnace and to use charges weighing about 15 tons.

The flame, after leaving the furnace, passes through two 375-h.p. Stirling boilers, in tandem, which reduce the temperature of gases going to the main flue to about 600° F. By this means 600 b.h.p. are obtained from each furnace from the waste heat. The ashes and partially burned coal drop from the fire-box into a stream of water, which carries them over a grizzly, the larger pieces of ash going to the slag-sluice, the smaller, containing coke and unburnt coal, being sluiced to the coke jigging plant, where the coke and coal are jigged out and the ashes sent to the dump. The coal and coke recovered are elevated to a bin from which they are taken to the briquette plant and there become a constituent part of the briquettes, thus obtaining a fuel value from an otherwise waste product. By this means 10% of the reverberatory fuel is recovered.

The slag is skimmed from the reverberatories twice in eight hours; it is allowed to accumulate until its depth is from three to four inches above the skimming plate in the front of the furnace and then skimmed into a stream of slime water, which granulates and sluices it through a cast-iron-lined launder to the slag-dump. By allowing the slag to accumulate in the furnace in this manner it is possible to skim the furnace rapidly, as much as 60 tons of slag being removed in 20 minutes. By this method the actual use of a rabble to 'pull' the slag is avoided, the rabble being used to keep the 'bay' clear of floating pieces of unfused silica and to prevent the flow being more rapid than the water can handle properly.

The matte is kept some distance below the skimming plate, making it impossible to 'pull' out any of the matte, thus avoiding explosions. The matte is tapped from the side of the furnace, through copper tap-hole plates, and run through cast-iron launders, lined with silicious material, to hot metal ladles of 10-ton capacity, and taken by the local tramway to the converters. The silica brick of that portion of the roof immediately over the fire-box (and for a distance of 30 ft. from the fire-box) lasts nine months and over. The brick is 15 by 6 by 3 in. It is the practice to clay, or fettle, the bridge-wall and sides where needed every 30 days. The bridge-wall plate is kept cool by a circulation of air by a pipe connection to the main flue. The utilization of the waste heat as a steam-producer and the saving of the coke from the ashes make a decided reduction in the cost of reverberatory smelting.

The briquette plant is a frame building 55 by 192 ft., containing four Chambers Brothers end-cut, auger-type brick machines, each machine having a capacity of 700 tons of briquettes in 24 hours. The briquettes are made of fine concentrate, fine first-class ore, pond slime, and fine coke from the reverberatory ashes. These materials are conveyed from the storage-bins by belt-conveyers to a pug-mill, from which they discharge into the brick machine proper, where they are further mixed and forced through a former by the auger of the machine in a continuous bar. This bar is cut into briquettes, weighing about 10 lb., by a revolving cutter peculiar to this type of machine. The briquettes are conveyed by a series of belt-conveyers to storage-hoppers, from which they are loaded into blast-furnace charge-cars as part of the charge.

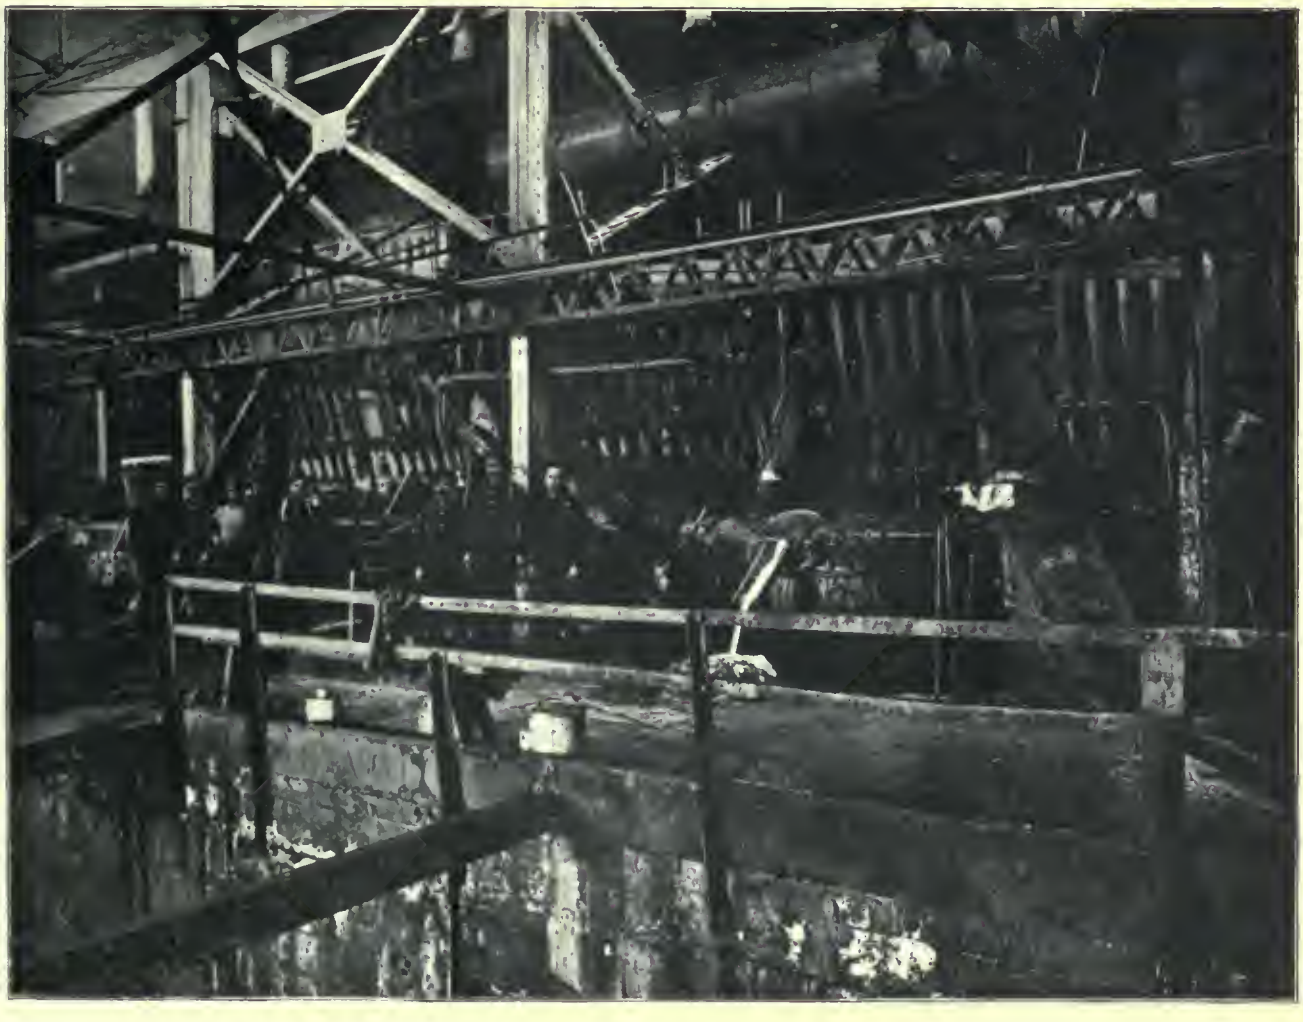
The blast-furnace building is of steel construction 82 by 269 ft. and contains three furnaces, two of which are 51 ft. and the other 87 ft. long, having a width of 56 in. at the tuyeres. The smaller furnaces have a capacity of 1,600 tons, the larger 3,000 tons of charge in 24 hours.

The bottom of the centre of the furnace is of silica brick, laid on water-cooled cast-iron plates, mounted on cast-iron columns, and has a gradual slope to each discharge spout. The 87-ft. furnace has three discharge-spouts and three settlers, but is otherwise built in the same manner as the 51-ft. furnace. The 51-ft. furnace has 88 four-inch tuyeres, and the 87-ft. furnace has 150.

The type of furnace used is the Mathewson patent blast-furnace. It is successful in operation and much easier to handle than the old style furnaces. Its advantages are that it has increased hearth-area with but two ends to bind and hold the crusts. Any crusts forming on the sides can be readily gotten rid of by allowing the furnace to run down, the crust either dropping or being readily barred. It has smaller radiating surface for the same hearth-area than the smaller furnaces, uses less coke, makes a flexible unit, because any part of the furnace can be handled as the case demands, and is susceptible of repairs without shutting down the entire furnace. Leaking water-jackets may be replaced without shutting down the furnace, thereby saving consider-

able time. It takes from six to eight hours to change a jacket. The procedure is to shut off the tuyeres on the jacket to be changed and the one opposite, allowing the water to circulate until all buckstays, tuyere pipes, etc., are removed, and the jacket ready to be pulled out; this chills a wall inside the jacket strong enough to hold the contents of the furnace. The new jacket is placed in position, all connections made, and the blast turned on and smelting resumed. The entire end of one furnace has been shut down, jackets changed, furnace cleaned out, and operations resumed; and during all this time (extending over ten days to two weeks) the other half of the furnace was in operation.

The circulation of the water through the jackets is as follows: Each individual tier of jackets forms a complete set with two feed-pipes and two discharge-pipes. In the case of the tier at the crucible end, the feed enters the crucible-jacket, the discharge from this going to the one immediately above, the discharge of this to the top jacket, from which it overflows to the waste-pipe. The 51-ft. furnace has three 7-ft. 45° unlined steel flues; the 87-ft. has five. All the flues discharge into a large brick and steel dust-chamber of the type adopted for the entire plant.



The Big Blast Furnace of the Washoe Smelter.

ASIDE from the kaolinization of feldspar by the ordinary processes of weathering, it seems possible that its decomposition may be brought about by the action of mineralizing vapors, as at Cornwall, England, where it was found that the feldspar of the granite on both sides of the tin veins, had been kaolinized. This change is attributed to the action of fluoric vapors, whose presence is pretty clearly indicated by the finding of such minerals as tourmaline and topaz.

IN EXPLAINING the deposits of lead and zinc ore in the Mississippi valley, H. Foster Bain says: The ores of this region are believed to represent concentrations of material originally disseminated through the surrounding rocks, particularly the Galena and upper Platteville beds. It is believed that the zinc and lead originally present in the crystalline rocks of the Lake Superior district were delivered by rivers to an especially favorable portion of the Ordovician coast, where in warm shallow waters they were partially concentrated by evaporation and were locally precipitated in quantity. The agents of precipitation were hydrocarbons or hydrogen sulphide, or both, derived from decaying masses of algæ of a peculiar type irregularly accumulated within certain shallow basins on the sea floor. The rising hydrocarbons continued to be effective throughout the period of deposition of the Galena dolomite. As the algæ matter became compressed the beds above broke and settled, leaving open spaces of peculiar form for the ultimate reception of the orebodies. The beds were slightly deformed, whereby the basins were accentuated and deep joint cracks were developed. The area was subjected to peneplanation and later to gorge cutting, whereby the overlying shale was cut away and a vigorous underground circulation was brought about. This circulation resulted in a concentration of the disseminated material, and, with the fall of ground-water level, the ores were successively reconcentrated until the present type was produced.

IN 1522 the mines of Tasco, Mexico, produced silver which was sent to Spain. This was the first silver sent from Mexico to a European country. The Tasco and Pachuca mines are the oldest worked mines in Mexico, the Aztec Indians having operated them at one time.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

A coal, oil, gas, and mineral lease provided that the lessor was to receive a *pro rata* share of all the oil and minerals produced, and if gas should be found, then a certain rental from each well. The lease also provided that the lessee should begin a well on the premises within a year or pay thereafter an annual rental of $16. No well was ever begun but the lessee paid the annual rent which was accepted by the lessor. The lessor was entitled to forfeit the lease for a failure to develop the premises, but he could not do so until he had first declined to receive the rent and had demanded of the lessee a development of the premises.

Monarch Oil &c. Co. *v.* Richardson, (Ky.) 99 S. W. 668.

An action to enforce a construction trust in a mining claim arising out of the fraudulent acts of the co-owner of the plaintiff, was held subject to the limitations, that an action for relief on the ground of fraud or mistake, shall be commenced within two years after accrual of the cause of action.

Delmoe *v.* Long, (Mont.) 88 Pac. 778.

A sale of the mineral and the severance of the estate carries with it the right to remove or use so much of the containing strata, above and below, as may be reasonably required for the proper mining of the mineral. And where there are no restrictions in the grant, the space that may be left by the removal of the mineral and by the removal of so much of the containing strata as may be reasonably required for the operation of mining, remains a part of the property of the mine owner until the exhaustion of the mine, and may be used by him during the continuance of the estate as he may see fit, on condition that such user does no injury to the surface. This right to use the exhausted part of the mine includes the right to haul mineral and drain water through such space from other mines.

Moore *v.* Indian Camp Coal Co. (Ohio), 80 N. E. 6 (February, 1907).

In a contest between two claimants to a mining claim, whether the action assumed the form of a suit in ejectment or to quiet title, the purpose was to determine which of the claimants was entitled to a patent, and, in order to make the judgment effective, it must be based upon the complaint, the allegations of which would show facts justifying the entertainment of the action and the rendition of the particular judgment or decree. To this end therefore a complaint in such an action must allege that the adverse claim was filed in the proper land office within the sixty days allowed by the statute.

Thornton *v.* Kaufman (Mont.), 88 Pac. 796 (February, 1907).

The sale of the output of an oil well will be taken to mean the total output, and the seller cannot divert a certain proportion of the output for the remuneration of the furnisher of air-pressure in bringing up the oil. This rule was applied where it did not appear that such air-pressures could not have been secured by a money consideration.

Crusel *v.* Tierce (La.), 42 So. 940 (February, 1907).

Material defects in a complaint cannot be aided by matters in the replication. The replication is responsible to the new matter or counterclaim alleged in the answer, and while its allegations may in a particular instance aid the answer, they may not in any case aid the complaint. Thus a complaint to quiet title to a mining claim which failed to allege that the adverse claim was filed in the proper land office within the sixty days allowed by statute, was not aided by the replication which contained an averment of such fact.

Thornton *v.* Kaufman, (Mont.) 88 Pac. 796, (February, 1907).

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The mineral marked X. from Nevada City, Cal., is specular Hematite.

W. H. B., of Ruch, Ore., sends: No. 1, Magnetite; No. 2, Magnetite and slaty rock.

Specimen from Benson, Ariz., marked L., is a rock containing specular Hematite, the oxide of iron.

The two samples from Woody, Cal., marked J. W., are: No. 1, Clay; No. 2, Rhyolite Tuff. They are of no value for Aluminum.

The specimens from Autlan, Jalisco, Mex., marked A. B., are metamorphic Slate or Quartzite. No. 1 contains Pyrite, and No. 2 Chalcopyrite.

To Keep Iron From Rusting.

There are many causes of the rusting of iron. It may be produced by atmospheric action alone, but in a majority of cases galvanism plays a large part in the destruction of the metal. Long experience has shown how rapidly iron nails employed in fastening sheets of lead and copper upon roofs are destroyed, the other, the electro-negative metal, remaining comparatively unaffected. The electrolyte, or exciting fluid, which by acting on the iron and not on the other metal, or by acting more upon the former than upon the latter, causes the electric current, is either actual water from rain or snow or the water vapor always present in the atmosphere. The decomposition of the water causes the liberation of oxygen at the positive pole, which is the iron, and this nascent oxygen rapidly combines with the iron. Now, it is claimed that red lead is an excellent material for protecting iron from rust and electrical action. Unfortunately, however, red lead is more electro-negative to iron than either copper or lead. Hence, should moisture by any chance get between the red lead and the iron, the destruction by rust is more rapid than when iron is in contact with copper or lead. This electro-chemical action is at the same time strengthened by the purely chemical action between the red lead and the carbonic acid always present in the air, an action which converts the red lead into ceruse, whereby an additional quantity of nascent oxygen is set free to rust the iron. It is also highly probable that the carbonic acid has an independent action upon the iron, thereby much facilitating its oxidation. It must not be forgotten that every porous place and still more every crack in the paint becomes sooner or later an entrance for water and carbonic acid. A good oil varnish is by far the best protection for iron, but it must, of course, be properly used. Not only must the iron be scrupulously, practically, and chemically clean and dry when the varnish is applied, but the covering must be without a flaw. Varnish will not adhere to greasy, rusty, or wet iron, and the contraction of the varnish on drying will cause minute cracks at such places and the iron-destroying gases will find their way through these cracks and get between the iron and the non-adherent varnish. Again, the varnish must be thoroughly dry before the iron is exposed to the weather. The varnish may be colored if the color does not interfere with the strength, continuity, and elasticity of the protecting skin, but is best dispensed with.—*Architectural Art.*

Some Problems in Mining Law.

We have received the following queries:

A. An incorporated company owns say nine contiguous claims entirely and a two-thirds interest in another claim contiguous to the said group of nine claims. The tenth claim, a one-third interest in which is owned by an outside person, is so situated that development work done on it in the way of excavations (shafts, drifts, cross-cuts, etc.) will be a benefit to the entire number of 10 claims, or at least can be so directed, without detriment to the tenth claim in which the outside person is interested and and the one upon which the work is done for the entire number of 10 claims. It is desired to know whether the entire amount of work under these conditions required by the Government each year to hold the 10 claims or $1,000 worth in all ($100 for each claim), can thus be legally done on the tenth claim and so recorded, although there is an outside owner not interested in the other nine claims or whether his partial ownership in the said tenth claim would vitiate the purpose so contemplated for the benefit for the entire number of 10 claims and only be good for holding purposes under the Government law for the one claim upon which the work is done. For work done under such conditions, what portion can be charged the private owner of the one-third interest in the claim upon which the work is done for the entire number of 10 claims, without defeating the purpose of the work? Would a payment of $33.33 be all that could be required of him, or if he did pay more than the latter sum would it cause any complications with the other claims?

B. Again, suppose that the said incorporated company, for the aforesaid purposes, had for a number of years done each year upon the said tenth claim $1,000 worth of work recording the assessment work for the 10 claims as having been done in a shaft on the said tenth claim for the benefit of the entire number of 10 claims, would the said private owner have any clue or claim upon or interest in any way in the other nine claims owned entirely by the said incorporated company? Suppose that the said company had only charged the said private owner $33.33 each year, could a greater charge be made hereafter based upon a proportional share of a greater amount of work done or would the old pro-rata charge have to be made? Again, suppose the said tenth claim should be worked as a separate proposition and $1,000 worth of work should be done on it during any given year by the said incorporated company, can the said private owner be charged more than his proportion of the amount of $100 annual labor required by the Government or can he be forced to pay his share of the $1,000 worth of work actually done by the said company? How would it be where the work was all dead work? How would it be where pay-ore is struck, say enough to wholly or partially pay for the work done? What would be the procedure where enough pay-ore would be struck to pay a small or large profit on the supposition that the private owner has not agreed to stand any portion of the work but stands aloof only to pay his portion of the $100 annual labor required when the bill for this amount of work is presented? Can the incorporated company do more than the $100 worth of work required each year by the Government without the said private owner's consent, even if he is not charged for more than his proportionate share of the said $100 worth of work? These questions are all based upon the supposition that the interests of the said company and the said private owner in the said tenth claim are all undivided.

C. Would it place the status of the matters stated any differently, after the work is done as stated, to make separate records of the work done for the nine claims and the one claim (two separate affidavits) and to send the private owner a certificate of the County Recorder, relating only to the work done, an affidavit furnished for the one claim—nothing being said about the other work—even though it was all done in one place at the same time?

To these questions we venture to reply thus:

A. Assuming that the work done upon the tenth claim was obviously done for the benefit of the other nine in pursuance of a common system of development, the mere status of the title of the tenth claim would possibly not be material as against a mere re-locator. At the same time the Land Department would not entertain an application for patent for the 10 claims in one group. The ownership of the one-third interest in the tenth claim being in a third party would destroy the unity of title requisite to obtain patent to the entire group. It is also possible that in the proceedings to obtain patent for the nine claims in one group, the Department would not consider the work done upon the tenth claim as applicable to the other nine, by reason of the ownership by a stranger of a one-third interest in the tenth.

Other contingencies might arise that would isolate the work on the tenth claim and prevent its being utilized as a means of working the nine claims. The individual co-tenant might protest against using the underground workings in the tenth claim as a means of extracting ore from the nine, a right of the co-tenant that has been upheld in some of the Courts. Or partition proceedings might be instituted, which usually result in a sale. These are all potential possibilities rendering it unwise to concentrate group work on a claim where third parties are interested who have no interest in the remaining claims in the group.

Aside from the improbability of establishing to the satisfaction of the Department, the essential fact that work done on the tenth claim would necessarily tend to develop the other nine and the suggested complications which might arise, business prudence would suggest concentration of work at some central point or points within the nine claims and thus eliminate the element of uncertainty. In fact it would be less costly to do the work on each claim than to litigate an adverse title initiated upon the asserted ground that sufficient work had not been done in one claim to hold them all, or that the work done on one did not as a matter of fact tend to develop the others. These are often close questions, and claim owners should always keep a safe distance from the danger line. The expense of one lawsuit would more than cover the cost of unquestionable development work on all the claims.

B. The owner of the one-third interest would only be liable for one-third of the work required to be done on the tenth claim to protect it annually from re-location in the absence of any agreement on his part to contribute more, or in the absence of a local statute making co-tenants practically mining partners. If he voluntarily paid more he would not thereby acquire any interest in any of the other nine claims, unless there was an express agreement to that effect.

Under the facts stated the corporation and the individual are tenants in common of the tenth claim. Without his consent and unless there is some contractual relation, expressed or implied, existing between them, or some local statute, the individual owner cannot be forced to contribute anything beyond his pro rata of the annual assessment work. If the corporation without securing the assent or contractual participation of its co-tenant, sees fit to work the claim extensively, it cannot hold him responsible beyond his pro rata of annual work required by law to be done. If, however, a profit is made by the corpo-

ration, it would be required to account to the co-tenant for his proportionate interest. This is the general rule, which may be and sometimes is modified by local statutes which should be consulted.

C. The mere name in which proof is made of the performance of the annual work would not alter or affect the relationship or liabilities of the parties between themselves. It would be advisable to make two separate affidavits of performance of annual work, one covering the nine claims held under one ownership, the other the tenth claim.

Telluride Ores.

By WALDEMAR LINDGREN.

*Interesting questions arise upon comparison of the pre-Cambrian Kalgoorlie deposits with those of Cripple Creek, which are of late Tertiary age. At both places gold tellurides occur on a large scale. At Cripple Creek, however, Mr. Ransome and myself have shown† that the deposition of these tellurides was largely in the nature of fissure-filling, and that it was not a deep-seated process, but went on within or a short distance beneath the cone of a volcano at a moderate depth below the surface. At Cripple Creek it is the rule to find the tellurides in crystallized form, whereas at Kalgoorlie they are almost without exception in massive form. Tourmaline, magnetite, and albite do not occur in the Cripple Creek veins, but adularia is formed quite commonly together with sericite.

From these data it seems fair to draw the conclusion that tellurides of gold may be deposited in large quantities, both near the surface and at a depth of many thousands of feet below it. As far as Cripple Creek is concerned this is encouraging for the prospects of deeper mining.

There are several very remarkable analogies between the two districts. Both were discovered about the same time, Cripple Creek a few years earlier than Kalgoorlie. In both the rich zone is confined within a very small area—within a square mile at Kalgoorlie, and within a few square miles at Cripple Creek. Both have produced similar amounts of gold: Kalgoorlie approximately $130,000,000; Cripple Creek about $140,000,000. In both, finally, the deeper workings, which at Cripple Creek have attained 1,500 ft., and in Kalgoorlie, 1,900 ft., have shown a diminished supply of ore. If the conclusion established above is true this decrease of quantity of ore at Cripple Creek cannot be due to the gradual increase in pressure and temperature in depth during the ore deposition. It is much more probable that other causes were effective, such as rapid movement of the solutions in a few channels, contrasting with more stagnant conditions within extensively fissured and more open country nearer to the surface.

Neither is it probable that decrease of pressure and temperature appreciably influenced the deposition at Kalgoorlie within an interval of 1,000 or 2,000 ft. Here, also, the explanation of the ore-shoots is perhaps rather to be sought in local causes favoring an intimate penetration of the rocks by slowly moving solutions.

In the Mother Lode district of California, from Angels Camp to Carson hill and the Stanislaus river, are a number of large deposits, representatives of a certain type of the gold-quartz veins of that State. The Utica, Lightner, and Melones mines are the best known of those working on these deposits. A comparison of the metasomatic processes active here with those of Kalgoorlie develops some interesting points to which sufficient attention has not been directed. The lodes are contained in amphibolites and amphibolite schists like those at Kalgoorlie, and are characterized by F. L. Ransome as follows: They are "in the main complex stringer leads. But the country-rock is usually much more altered, and may be heavily impregnated with pyrite near the vein. It is often changed to a soft grayish rock consisting chiefly of carbonates of lime and magnesia, with sericite, and sometimes a little chlorite. Such altered and pyritized country-rock is too poor in gold to pay for working alone, but is often run through the mills for the sake of rich stringers which intersect it. These veins are usually richer in carbonates than those in the black slate areas, and in certain parts of the district are rich in tellurides." Mr. Ransome further mentions the occurrence of albite in the quartz filling of the veins, as well as in the ore resulting from the replacement of the amphibolite, and describes the tellurides, coloradoite, petzite, hessite, melonite, calaverite, and altaite, which occurred at Carson hill intergrown with free gold. A recent examination of a suite of specimens from Angels Camp and Melones shows that some of the altered rocks consist of sericite, with embedded grains of calcium-magnesium-iron carbonates and pyrite. In other places the carbonates prevail over the sericite, while in a third and very common type much of the sodium, abundant in the amphibolite, has been retained as albite in the altered rock. Large grains of carbonates are separated by a granular mass of quartz, albite, pyrite, and sericite.

At the Melones mine a specimen was found to contain sharply defined octahedrons of magnetite, embedded in the usual sericite felt of the altered amphibolite; this is, I believe, the first instance recorded of the occurrence of a magnetite as a product of rock alteration in a California gold-quartz vein. Tourmaline has not thus far been found.

The California veins are, as well known, of early Cretaceous or late Jurassic age, and were formed at a considerable depth below the surface. The remarkable similarity of the rock alteration at the Mother Lode mines to that at Kalgoorlie shows conclusively a deposition of the gold-bearing veins from solutions practically identical in their general composition.

*Abstract from paper on 'Metasomatic Processes in the Gold Deposits of Western Australia,' by Waldemar Lindgren in *Economic Geology*.

†'The Geology and Gold Deposits of the Cripple Creek District.' Prof. Pap. 54, U. S. Geol. Survey.

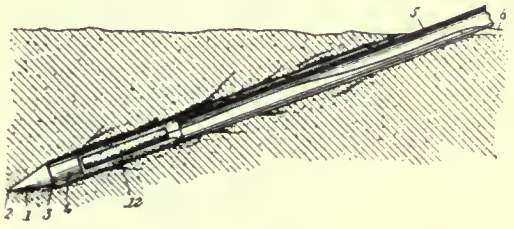
THE possibility that intense electrical waves used in wireless telegraphy may cause sparks to pass between conductors where they are not expected has been pointed out, but up to this time no disaster had been attributed to this effect, as the probabilities are much against it. Now, the mysterious accident which caused the blowing up of the French war vessel *Jena*, is attributed by a French wireless expert to this cause. The reasons for the charge have not been given in full, and until they are heard, judgment must be suspended. It may, however, be pointed out that the magazine of a war vessel would be the last place where one would expect to have trouble from this source. The vessel itself is a nearly perfect metallic shield, through which no electric wave could pass. To produce sparks within a metallic hull it is necessary that the source of waves shall itself be within the same inclosure, and even then the bulkheads should, under normal conditions, be effective screens.—*Electrical Review.*

RESIDUAL CLAYS, usually of ferruginous character, are found in many portions of the United States, but reach their maximum development in that portion lying east of the Mississippi and south of the southern margin of the ice-sheet of the glacial epoch.

MINING AND METALLURGICAL PATENTS.

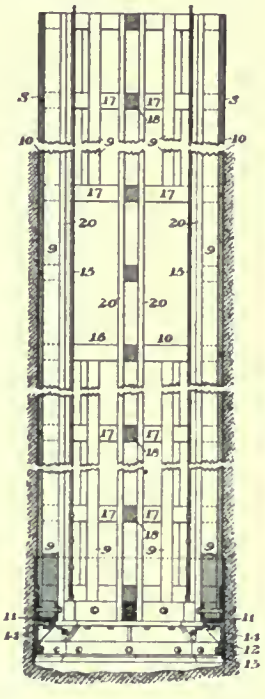
Specially reported for the MINING AND SCIENTIFIC PRESS.

DEVICE FOR INSERTING EXPLOSIVE CHARGES.—No. 848,512; Rosendo Torras, Brunswick, Georgia.



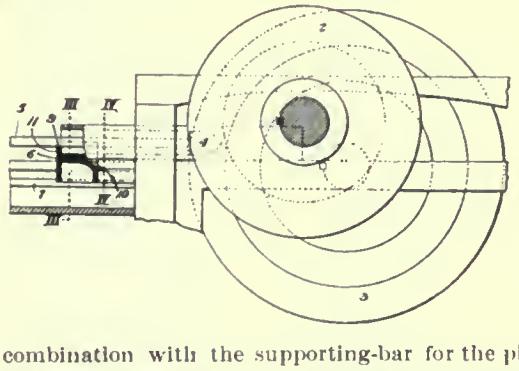
A device for inserting explosive charges, comprising a tube having a groove the entire length thereof, a pointed head detachably connected to one end of the tube, a head having a sharp point, a cylindrical shank portion fitting within one end of the tube and a shoulder fitting the end of the tube, and a cap adapted to be inserted in the other end of the tube.

APPARATUS FOR SINKING SHAFTS.—No. 846,816; Ralph Baggaley, Pittsburg, Pennsylvania.



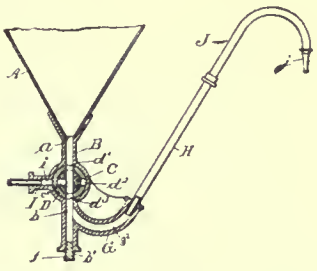
Means for sinking shafts including a permanent casing suspended from its lower end and made up of superimposed sections capable of being assembled as the casing is lowered.

BLANK-SUPPORT FOR TUBE-MILLS.—No. 848,285; George H. Blaxter, Beaver, Pa., assignor to Pittsburgh Seamless Tube Company, Beaver Falls, a Corporation of Pennsylvania.



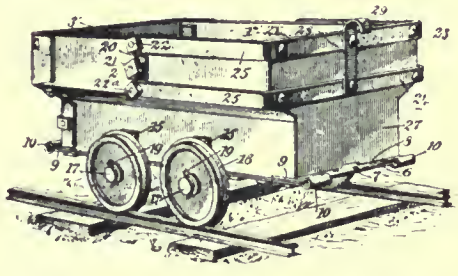
In combination with the supporting-bar for the plug or point of a piercing-mill, a bearing slidingly mounted parallel with and underneath the bar, and provided with an open top, and a lower portion adapted to engage and support the hollow billet

SETTLING-TANK.—No. 845,520; John M. Callow, Salt Lake City, Utah.



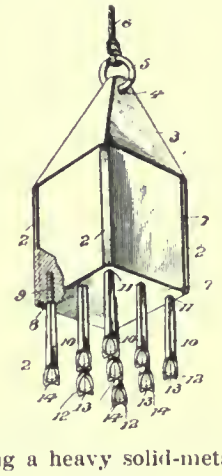
In a settling device, a tank provided with a discharge-opening, an exit-casting attached to the lower end of the tank and having a vertical channel connecting with the opening in said tank, a connecting-pipe, said pipe and the casting having a lateral outlet-passage connecting with the vertical channel through said casting, said discharge elements being provided with a valve-chamber, a three-way valve therein, means to operate the same, and a pressure-pipe connecting through said valve with the channel and with the lateral outlet.

MINE-CAR.—No. 842,670; Charles A. Keller, Rosedale, Indiana.



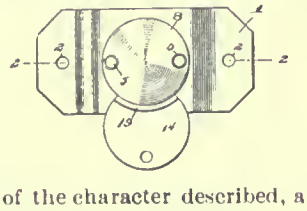
In a car of the class described, in combination, a body having a movable door, a bail attached to said door, and means for pivotally connecting the bail to the car, whereby the door may be swung to the outer side of the opposite wall of the car.

CHURN-DRILL.—No. 848,502; Josiah B. Scovell, Duluth, Minnesota.



A drill comprising a heavy solid-metal block, and a plurality of downwardly extending cutting-bits secured within the lower face of said block.

CHECK-LOCK FOR MINING-CARS.—No 848,441; Charles A. Cabell, Carbon, West Virginia.



In a device of the character described, a lock having a corrugated key-recess, and a curved groove extending into said recess, in combination with a corrugated key, said key having a curved slot, and a ball in said groove.

The Garfield Mill of the Utah Copper Company.

Written for the MINING AND SCIENTIFIC PRESS
By L. H. BEASON.

The concentration of ore from Bingham will begin next week at Garfield, the new smelter town, 15 miles west of Salt Lake City. The first section of the Utah Copper Co.'s gigantic plant is now ready for operation. The work of trying the machinery has been proceeding for a week or more by the use of temporary power provided for that purpose. Work on the second section is progressing rapidly. The operation of this new mill will undoubtedly be watched with keen interest by metallurgists throughout the country, for the reason that it is almost alongside the plant of the Boston Consolidated, which is being constructed on an entirely different plan, although the ore to be treated is identical in character. The Utah Copper will crush the ore with rolls and Chilean mills, whereas the Boston Con. will use stamps of the Nissen type.

The plant of the Utah Copper Co. is designed for a capacity of 6,000 tons of ore per day. The dimensions of the main building are 600 by 508 ft., this covering two sections, each of 3,000 tons capacity. The main receiving bin has a capacity of 46,000 tons, and there is another bin for crushed ore, that will hold 14,000 tons—a total storage capacity of 60,000 tons.

Operations will be divided into three departments—coarse crushing, fine crushing, and concentrating. Each section has its own coarse-crushing department, containing two No. 7½ gyratory crushers with a capacity of 100 tons per hour—a total of 400 tons per hour reduced to ¾-in. size. In each department there are two 54 by 20-in. roughing rolls.

The fine-crushing department for the entire mill will contain 36 six-foot Chilean mills and 20 sets of 16 by 36-in. crushing rolls; also the necessary feeders, elevators, and screens.

The concentrating department for the entire plant is built on three floors, each successively lower. These floors have an area of 120 by 600, 164 by 600, and 120 by 600 ft., respectively, the total area being 242,000 sq. ft., or approximately 5.6 acres of reinforced concrete. In this department will be placed 72 jigs, 48 Wilfley tables, and 1,104 six-foot vanners of the suspended type, being a modification of the Johnston concentrator. This department will contain 24 four-compartment classifiers and 384 nine-foot conical settling-tanks.

The total area covered by the main building and ore-bins is approximately seven acres, the total floor space in the main building being over eight acres. The total area covered by shops, warehouses, yards, reservoirs, etc., is about 20 acres. The machine-shop, equipped with every modern appliance, has a ground area of 100 by 56 ft. The carpenter-shop covers an area of 48 by 72 ft. The warehouse is 100 by 52 feet.

The mill is so designed that each of the 3,000-ton sections is made up of six units of 500 tons capacity each, making 12 such units in the entire plant. Each one of the units is a complete mill of itself, that is, any of them can be run independently of the others, each having its independent power. By this arrangement, a steady output can be maintained whenever repairs become necessary.

There are two storage reservoirs—one for low-head service and one for affording a high head. The former is 380 by 180 ft., and has a capacity of 6,000,000 gal. The high-head reservoir is 100 by 50 ft., and has a capacity of about 500,000 gal. water. The power-plant will have sufficient capacity to supply power for the Garfield works, as well as for the mine and mill at Bingham. To supply the latter, a transmission line 17 miles long has been constructed. The power-plant contains 20 water-tube boilers having a capacity of about 600 h.p. each, a total of 12,000 horse-power.

The engine-plant consists of five reciprocating engines, directly connected to high-potential alternating-current generators. Two of these sets are of 1,500 kw. capacity each, the other three being 2,250 kw., or 13,000 h.p. The dimension of the power-house building is 288 by 158 ft. There are two reinforced concrete stacks in connection with the steam plant, each 12 ft. inside diameter, and 180 ft. high.

The pumping plant, designed to supply water from the source of supply near the power-plant to the reservoir near the mill, consists of three electrically driven direct-connected turbine pumps, having a combined capacity of 10,500 gal. per minute.

The Utah Copper Co.'s enterprises, with which the Guggenheims, or American Smelting interests, are identified, are under the general management of D. C. Jackling. R. C. Gemmell is general superintendent and Frank Janey is superintendent of mills.

The contract for the first-section building was let to the Minneapolis Steel & Machinery Co., of Minneapolis, Minn. When it was decided to double the capacity, that is, add 300 ft. to the mill, this firm also secured that contract. For the whole plant, over 4,000 tons of structural and corrugated steel have been used.

ELECTRIC HEATING.—A large number of industrial processes depend upon the production of high temperature by fuel heating. In many of these cases, in the course of general advance in practice, the limit of temperature aimed at has tended to rise considerably; but it has, unfortunately, seldom been possible to prevent a corresponding decrease in the efficiency of the utilization of the coal. In this connection, remarkable progress is being made in the application of electricity for the production of high temperatures. Serving, at first, solely for the initiation of new industrial processes, demanding temperatures quite beyond the scope of fuel heating, electric heating is already being widely applied in cases where the temperatures required are just within the limit attainable with gas or coal firing, and the general tendency is undoubtedly toward its use for still lower ranges of temperature. The chief advantages of the application of electricity in this connection may be said to lie in that it enables the heat to be generated where it is required — inside, rather than outside, the chamber containing the material to be heated; in the simplicity of a delicate regulation of temperature; in the ease with which the furnace or kiln can be provided with a really efficient heat insulation, capable of minimizing the thermal losses to the outside air.— R. S. Hutton.

THE recent statements made by the trust companies of the State of New York are illuminating. The statements are made as of February 26, 1907, and they may be compared with the statements as of February 20, 1906. This year these trust companies owe to their depositors in round numbers $23,000,000 more than in 1906. A year ago the reserve against their deposits, which were then quite a little in excess of $1,000,000,000, was held with approved reserve depositories to the extent of $118,000,000. This year the amount so held is $94,000,000, a decrease of $24,000,000. But the cash items, namely, specie and legal tenders and national bank bills, held by these trust companies in February, 1907, amounted to $59,000,000 as against only $23,000,000 in 1906. Here is an increase in actual cash holdings of $36,000,000. Of this increase in cash holdings the sum of about $31,000,000 is increased specie.

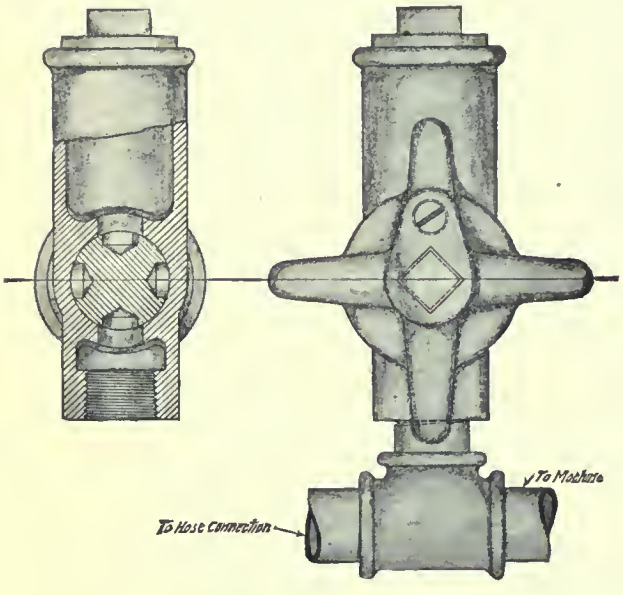
New Mill of the Utah Copper Company.

In the distance is the Wasatch range, at the base of which is Salt Lake City. In the middle distance is the alkali waste made by the recision of the lake.

Rock-Drill Lubrication.

Strange as it may seem, until recently there was little attempt on the part of rock-drill manufacturers to provide means for efficient or economical lubrication of the machine, and even now the devices in use are remarkable, not for their fitness, but rather for their crudity and wastefulness.

In the Chicago Giant rock-drills the Chicago Pneumatic Tool Co. provides means for automatic lubrication, but, as there are thousands of rock-drills of other designs in use, which are wearing away their lives in needless friction, this company has designed an independent rock-drill oiler (shown in illustration) which can be attached to the hose



connection by using a standard pipe nipple and T. This device is constructed so that at each quarter turn of the star-wheel a defined quantity of oil is delivered and passes into the drill with the operating fluid. The upper part of the oiler-body is made to form a reservoir-chamber for the oil, and is of sufficient capacity to hold from 50 to 60 'doses,' which are measured out to the drill by turning the star-wheel. One filling of the reservoir-chamber will last a day's run, allowing one dose to the machine at each change of steel or more frequently if deemed necessary. The position of the arms on the star-wheel coincides with the position of measuring pockets in the oiler, and provision is made for automatically latching in the proper position at each quarter turn of the star-wheel. As everyone who is familiar with mine work knows, rock-drills have to be operated where the light is poor, and also that in all conditions of drilling, on the surface or underground, there always is an abundance of dust or grit; consequently, with the old system of oiling, the machine was liable to get ingredients introduced with the oil that caused grievous trouble in its internal organization. To prevent this we have provided a strainer in the mouth of the filling-chamber, which can be easily removed for cleaning when necessary.

The addition of a small quantity of flake graphite to the oil will be found beneficial. The graphite and oil should be mixed as thoroughly as possible before placing in the oiler. One teaspoonful of fine flake graphite to a pint of oil will give good results. The mixture should be well shaken before filling the oiler, then the vibration from the operation of the machine will keep the graphite in suspension in the oil when it is in the reservoir.

Technical Schools.

THE UNIVERSITY OF ILLINOIS is sending out a leaflet describing the 'School of Railway Engineering and Administration.'

Commercial Paragraphs.

ALLIS-CHALMERS CO. announce the opening of a new branch office at 316 Godchaux Bdg., New Orleans.

T. H. PROSKE, of Denver, manufacturer of the Ajax drill-sharpening machine, recently shipped one of his machines to St. Petersburg and one to Berlin.

THE PACIFIC TANK CO. and the NATIONAL WOOD PIPE CO. have moved into their permanent offices in the Hanford Bdg., 268 Market St., San Francisco.

THE Ohio Copper Co., Bingham, Utah, controlled by F. A. Heinze, recently placed an order with the UTAH MINING MACHINERY & SUPPLY CO., J. E. Galigher, Mgr., Salt Lake City, Utah, for 288 standard 8-ft. Callow tanks, which are manufactured by the company. This order calls for delivery within four months. The company now has orders aggregating 850 Callow tanks for shipment within the next four months, besides orders for 20 duplex Callow traveling-belt screens.

THE Cleveland-Cliffs Iron Co. has placed an order for a 60-drill Sullivan air-compressor for its new Maas mine at Negaunee, Michigan. The machine will be of the Corliss cross-compound condensing two-stage type, with large receiver intercooler. The steam cylinders will be 24 by 46 in. diam., with 48-in. stroke, and the air cylinders 40 by 24 by 48 in., with a displacement capacity of 4,000 cu. ft. free air per min. at 60 r.p.m., or nearly 5,000 ft. at 70 r.p.m. The compressor will be built at the Chicago works of the SULLIVAN MACHINERY COMPANY.

The Witte Iron Works.

We illustrate herewith the new plant, now under construction, of the Witte Iron Works Co., of Kansas City. When completed, it will be the largest, most complete, and up-to-date gas and gasoline engine manufactory in the West; it is practically fireproof, being of steel, brick, and stone construction. The establishment has 60,000 sq. ft. of floor space, equipped with the finest of modern machine tools, electric power, traveling cranes, private switches, with enclosed loading warerooms. The company has its own natural gas wells and water supply, so that it will operate an independent electric lighting plant and telephone service, with modern accommodations for the benefit of visiting customers and employees. The new plant will extend from 16th and 17th St., and from Oakland Ave. to Eastern avenue. It is situated on the Missouri Pacific and Kansas City Southern railroads. This plant will be used exclusively for the manufacture of stationary, gas, and gasoline engines, traction engines, farm portable engines, electric lighting plants, mine hoisting engines, pumpers and irrigation equipment, in sizes from 2 to 100 horse-power. This company has been manufacturing many of the above line of engines in Kansas City for over 22 years. The increased number of sales in the last few years has over-taxed the capacity of the present plant. The new plant will be enabled to make immediate deliveries from stock and to extend the company's business to foreign countries. It is expected to have the new plant in operation in about 60 days.

Editorial.

IT IS A YEAR since the earthquake-fire. We celebrate the anniversary by publishing this special number, in which an account is given of the reconstruction of San Francisco, together with other matter appropriate to the occasion.

REINFORCED CONCRETE is the dominant feature in the rebuilding of San Francisco, therefore the article on this subject by Mr. Lewis A. Hicks, himself the engineer and builder of several of the largest structures now in process of erection, has a special value.

WE TAKE special pleasure in publishing the article on mining finance by Mr. J. R. Finlay. It is all that such a contribution to technical literature should be, for it is practical, interesting, and suggestive. The subject is one that invites a broad discussion and we hope to hear from other mining engineers.

PARTICULAR INTEREST will be taken in the article on the re-construction of San Francisco, written by Mr. Charles Derleth, Jr., associate professor of structural engineering in the University of California. He is outspoken in his criticism and judicious in his suggestions, so that his observations have a value that is not wholly local.

SAN FRANCISCO is being fumigated. The process is unpleasant. But it will do good. Civic spirit is being aroused. The structural rehabilitation of the city is emblematic of a new era of municipal reconstruction. A community such as this cannot be fooled all the time nor will it allow itself to be exploited forever by gangs of rascals, masquerading as lawyers and politicians.

THE ILLUMINATION of the ruined City Hall indicates a curious mental obtuseness. Why illuminate the shame of San Francisco? It is a ghastly monument to dirty politics. Some people complain because the ruins are not removed and the City Hall rebuilt. We would like to see it surrounded by an ugly iron fence and preserved for a hundred years as a warning against municipal corruption.

IT IS ESTIMATED that the total loss by the earthquake-fire was $400,000,000, but even this does not include an immense amount of private property in the form of pictures, objects of art, jewelry, and books. The total area burned exceeded 3,000 acres, or 4.7 square miles, containing 520 blocks, and 25,000 buildings, one-half of which were residences. It was the most costly conflagration in human history.

NEWS FROM MEXICO concerning the earthquake is meagre, owing to interruption of telegraphic service, but it indicates serious injury to the towns on

the west coast. We hope that we have heard the worst and that the injury to life and property has been lessened by the fact of the origin of the tremors being at some distance out to sea. As the mining districts are in the mountains and on the high plateau, the earthquake does not seem to have affected them.

WE THOUGHT we had troubles of our own, and we were even so self-conscious as to speak of them on another page, but when we read what had befallen the editor of the *Comet* at Johnson City, Tennessee, it became apparent that we had taken an exaggerated view of our misfortunes. For the gentleman in Tennessee says: "With our foreman at home shot three times, a printer in the Blountville jail half shot, another in the office not worth shooting, the *Comet* is issued under great difficulties this week."

IN REGARD to the wholesale bribery that has disgraced San Francisco, it is significant that most of us would prefer association with the man who gives the bribe rather than the man who accepts it. This is a perverted notion. The man that is bribed is, in most cases, an invertebrate sneak, without principle and without self-respect, not aware of the dishonor attaching to the deed. The man that does the bribing is usually possessed of wealth and education, with a full knowledge of the meaning of the act he perpetrates; he has principles, he has responsibility, he has intelligence. His crime is done with open eyes; his is the greater blame.

THIS CITY has made a pitiful exhibition of municipal corruption and the detection of it has been made as little dignified as possible. The washing of dirty linen has been done with callous effrontery. Even the administration of the law has been turned to a vulgar comedy. And this aspect has been emphasized by the daily papers, with their wearisome pictures of indicted spoilsmen and ineffective comment on the course of events. A corrupt city government could have been rendered impossible if San Francisco had possessed some strong newspapers. Now they howl like a pack of coyotes in the chill hour before the dawn.

CLUBS AND RESTAURANTS used to make San Francisco a haven of comfort to the weary mining man. Of the clubs, the Cosmos escaped the fire, while the Pacific Union, University, Bohemian, and Olympic have excellent temporary quarters in large residences in the western addition. As for restaurants, the city is already in a position to maintain its former reputation, for the Palace, St. Francis, Fairmont, Tait's, and Sevrn are all up to the highest standards. Those who come from the regions where beans and bacon form the staple diet will find San Francisco as delightful as of yore.

OWING TO the fact that several geologists of the United States Geological Survey have resigned, to take more lucrative positions in the service of mining houses dominated by the Guggenheims, Lewisohns, and other representatives of a historic race, it has become a nice question how many capable men can be held in the service of the Government, which pays salaries so much smaller than those of the big corporations. Like professors, and editors even, the geologist at Washington will have to take much of his recompense from the love for his work. And he must be steadfast in his affection for scientific ideals, he must be wary of temptation, for they say on the Survey that

"The Guggenheims will get you
If you dont watch out."

San Francisco.

ON AUGUST 1, 1836, Jacob P. Leese wrote from Yerba Buena to a friend at Monterey, California, saying: "Leigh low and look out sharp for this Place as we are a gowing to do a snorting Buisiness. Do not make yourself uneasy about Buisiness here for all gows on straight." Yerba Buena was the settlement that became San Francisco, and Jacob Leese was the first merchant of what was destined to be a great mercantile community. His optimism, told in this homely language and early reformed spelling, has been often expressed since then in more resplendent phrase; it has passed from words to deeds. The barren sand-hills have been made gracious with verdure; on the wind-swept dunes rise many storied structures, knit with steel and clothed with stone; the shallows of the shore have been gained to traffic, and the waters of the estuary bear the commerce of a continent. Yerba Buena has emerged from its Spanish background and has become the San Francisco of an American California. San Francisco. The name sounds with an exquisitely melancholy cadence to those that have known her in the days of her prosperity, her disaster, and her recovery. Bret Harte named her "the warder of two continents," he called her "serene, indifferent of fate," who drew all things to her, "small or great." Today she guards the portal of the Pacific aud takes it upon her to forbid the entrance of the coolies of Japan, with a spirit and with a manner that are blended of greatness and smallness, dignity and burlesque; in the midst of a reconstruction that challenges the admiration of the civilized world, she sends her indicted mayor, the first violin of a vaudeville, and the last expression of labor unrest, to represent her in an international negotiation at Washington; in the very act of rising gloriously from the effects of a conflagration that enkindled the generosity of the world, she exhibits the scandal of a municipal corruption that makes the smoke of her fire reek like a tannery. Surely, San Francisco epitomizes the greatness and the smallness of our humanity, and if we love her it is with a devotion that sees, beneath the tawdry politics and the strange antics, the warm heart of a great personality. For cities have characteristics that give them an identity. San Francisco wears her heart upon her sleeve, she is the most Bohemian of the new cities of the world, as little self-conscious as conventional, with the artlessness of a spoilt child and the artistic sensibility of a beautiful woman. Proud of her origin as the City of the Argonauts, rich in the promise of her dominion of the Pacific,

headstrong in the insistence of her supposed rights, serene amid the shock of a cosmic unrest, she appeals to the imagination of a poet and to the perception of the artist. We have known San Francisco at her worst, under her mountebank mayor and in the stench of her putrid politics; we have seen her under a catastrophe that looked like the end of the world, and amid a disaster that had no promise of a morrow; she has exhibited civic instability and geologic disquiet; she has faults that are superficial and she has those that go beneath the surface, riving the rock; and yet, despite them, almost because of them

"With all her *faults* we love her still."

Looking Back.

THESE columns have not reflected the troubled conditions under which we have labored during the past twelve months, and our readers have not been wearied with any recital of woes incident to the great disaster that befell San Francisco a year ago. But the present anniversary of that event seems to warrant a description of circumstances, some of which are eloquent of the human nature that makes the whole world kin.

The earthquake occurred at 5:13 on the morning of April 18, 1906. Owing to the bursting of gas mains and the crossing of electric wires, a dozen fires broke out immediately. At 10:30 our offices at 330 Market street were doomed. Those of us who lived on this side of the Bay could do nothing, for the burning city was placed under military control early in the morning and admittance from the suburbs was forbidden. But among our people living in San Francisco itself were two, who, despite the urgency of their own affairs, found a way to our offices and did their utmost to save valuable papers. Fourteen times JOHN J. YOUNG and PHILIP F. SAGE climbed to the top of the six-story building, which had been racked by the earthquake and was surrounded by the encroaching conflagration. A co-tenant in the building, Mr. Charles E. Townsend, had secured a light delivery wagon with the purpose of saving his library and it was promptly arranged that they should help him to remove his books, while he in return was to aid them, giving the use of the vehicle for transporting such material as they rescued. After two hours of unremitting labor, the most valuable records having been secured, this wagon-load was taken to the Central market, in the basement of which it was stored. But it was not long before this building also was threatened; Mr. Townsend secured another vehicle and hurriedly transferred his own material and ours also to a safer place. To make a long story short, he had to move it six times, losing a few things each time, until finally a hole was dug in a vacant lot near the Hollushickie Club, the members of which helped to bury everything under a safe cover of sand, together with the pictures and other valuable possessions of the club. There it remained until the conflagration had spent itself, on the evening of April 20. A week later, the salvage was disinterred and our share of it was brought to Berkeley. In the meanwhile 330 Market St. was an insignificant part of a vast ruin. On the top of the crumbled brick and twisted iron, we found our safe. As soon as it was cool, an examination was made. There was a big hole in one side; it was apparent that the thin iron sheathing had been punctured in falling and the cementing material was mere rubble. All the safes in San Francisco proved a delusion; so much care had been taken to make them burglar-proof that they had ceased to give protection from fire. Hauling it to the water front, we turned a stream of water into the safe, washed out the cinders, and panned them—like miners—securing $55 in currency and a medal. The last had been awarded to the MINING AND SCIENTIFIC PRESS at the Chicago Exposition, it was in an aluminum case, and while the plush had become soot, the metallic case had protected the medal itself, so that it was only slightly oxidized. Of course, all the paper currency and account books in the safe had vanished in smoke—a contribution to that vast column, which like the clouds of steam from an erupting Vesuvius had darkened the sunshine during the days of the conflagration.

As we were among the first to know of our loss, so also we were among the first to make a new start. At noon on April 18 offices were engaged at Berkeley; by 2:30 P. M. on the same day arrangements had been made for printing. The issue of that week had gone to press and had been consumed in San Francisco, so a single sheet was sent out in its place on Friday evening, April 20. In order to ensure transmission in the mail, this sheet was sent by letter postage and a number of women refugees were employed in addressing envelopes. For ten weeks, until an addressing machine arrived from Chicago, all the copies of the paper were addressed by hand. By immediately notifying the postmaster at San Francisco, our mail began to reach us a week after the disaster and it brought the revenue so much needed at a time when all the banks were closed. Our agents were directed by telegraph to secure new plates from the advertisers and in the meanwhile eight pages were reproduced by zinc etching from the issue of April 14. This work was done at Oakland, at Fresno, at Los Angeles, and at Sacramento, each establishment being able to do only a little for us, owing to the general rush of orders from other publications. In order to get good half-tones we sent photographic prints to Chicago. Thus, in one way and another, the issue of April 28 and the succeeding weeks appeared, a few days late, but looking robust. The publication of the paper was hindered by the call for job printing, which was apt to get preference at a time when such work received high payment, and as we had no definite contract with the printers at Berkeley, themselves publishers of an evening paper, we had many hours of anxiety. A new plant for a composing room had been ordered by telegraph, and it began to arrive from Philadelphia in June. As we had decided early in February to reduce the size of the Journal in July, the tinted paper for the cover had been ordered several months previous, and it had arrived at the railroad terminus before the disaster; nevertheless, we did not get that cover-paper until the first week in July, just too late for the first issue in the new size, which therefore appeared with

a white cover. At this time the congestion of railroad traffic was tremendous, the Southern Pacific lines were glutted, at Oakland and Sacramento there were thousands of cars consigned to people that had no warehouses and had postponed unloading. Fourteen thousand cars stood on the tracks and, owing to a lack of system, the identity of them became lost, so that it was months before consignments could be traced and received. At the end of June our composing room was in operation and despite the lack of 'sorts', we managed to do fairly well. In the meanwhile the printers at Berkeley were giving poor service and charging three times the usual price, so that we were uncertain from week to week as to when the journal would be issued. Just in the nick of time a printing establishment was opened in San Francisco, so we bought a motor car to transport the 'forms'; thus we secured better service, although hampered then and up to the present by the delay incidental to the distance—14 miles of land and water—between the composing room and the printer, followed by the further transfer to the bindery and to the post-office.

However, that is all over now. The experience has been enriching. While the fear of the Lord was on them, many people behaved handsomely, but the strain was too great for some of them. In contrast to the personal hospitality and general humanity of the citizens of Oakland and Berkeley, who housed and fed the refugees from San Francisco, there was also an exhibition of greed disgraceful to what is termed civilization. Of the stealing of supplies intended for those in distress, of the official corruption that even the horror of a great catastrophe could not restrain, we have no space to tell. Our own experience was enough. We had dealings with the proprietors of three newspaper printing-plants, two at Berkeley and one at Oakland, and of two of them it can be said that they gave a lurid exposition of the pitiful smallness of man when possessed of the hunger for money; they illustrated the reason why the daily press is so often without influence, because it is controlled by creatures without character. For the rest, the account is more than balanced by the generosity of friends, the loyalty of our staff, and the integrity of many with whom we had business dealings. Our advertisers, almost without exception, paid for the advertising appearing in the issue that was burned and treated us with considerate kindness during the time of trouble. Blake, Moffit & Towne, from whom we get the paper on which the PRESS is printed, supplied us from their best stock and took no advantage of the higher prices ruling after the disaster. We lost all our files, of course, but numerous offers of old copies of the journal were made by subscribers in different localities and within a couple of months we had one complete file, covering 46 years, and several sets extending over periods of ten and twenty years. Our contributors, the leading men of the profession, helped with articles and notes in most encouraging fashion. Of offers of money in sums ranging from $100 to $10,000 it is hardly befitting to speak, except to record expressions of goodwill that were more affecting than even the burden of anxious hours. To the members of our staff the difficulties to be overcome only presented the opportunity for demonstrating the sort of resource and energy that have made the West, and we can say deliberately that the calamity created a solidarity such as years of quiet prosperity could not have evoked. And what holds true of them is true also of our relation to the community in which we live; we have shared the trouble, so too we share the stimulus of the rehabilitation of a great city. Newcomers last April, we are today the pioneers of another era.

The New Smelter.

GOOD progress is being made in the construction of the copper smelter at San Bruno, just south of San Francisco. These works will be an important factor in making San Francisco a metallurgical centre, for the lead smelter at Selby may also be regarded as a part of the City's industry. Copper ore will come here from Shasta and Madera counties, in California, and from Alaska; silicious material from Nevada will give the required mixture; in addition, the Dairy Farm mine in Placer county is relied upon for an assured supply of ore. This property was bought by the Guggenheims from L. C. Trent two years ago, and it has been opened up since then, so that a body of copper-bearing iron pyrite 1,000 feet long and 50 feet wide has been proved to a depth of 500 feet, carrying sufficient value in the precious metals and in copper to make exploitation profitable. The mine is seven miles from Sheridan and ten miles from Lincoln, both stations on the Southern Pacific railroad. A branch line is to be built, and over it will come the supply of ore well adapted to serve as a base for the silicious material of the precious-metal mines tributary to San Francisco. The new smelter at San Bruno is expected to be in operation at the end of the current year. It consists of roasters, blast-furnaces, reverberatories, and converters; the first unit will have a capacity of a thousand tons per day, and it will be doubled or trebled as growth of business warrants it. The product as it comes from the converter will contain 98 per cent copper; for further refining it will be sent to New York, which is the main distributing point for the metal—a fact rendering it economical to pay freight on the small percentage of impurity in the blister copper. Transport by rail costs $14 to $15 per ton, a rate which competes successfully with shipment by sea, not to mention the saving of interest on the value of the copper while in transit. The freight to Denver is the same as to New York, an illustration of the anomalies of railroad transport, due to pooling between railway companies. We regard this smelting enterprise as of great importance in the development of industry on the Bay of San Francisco.

Nor do we fear any injury by reason of smelter fume. The engineers of the smelter company have had ample warning from Salt Lake and elsewhere of the importauce of avoiding such trouble and, in consequence, they are building a stack 305 feet high, the top of which will be 400 feet above the Bay. Dust chambers of unusual size will be a further safeguard. In addition, a sulphuric acid plant will be operated during those months when

the wind blows from the north, and the effect of this will be to entrap the noxious fume and utilize it in the manufacture of acid to be used in making super-phosphate, which, as a fertilizer, will find a ready market in California. As is generally known, the prevailing wind is from the west, and it is only during a few days in the year that the direction of the air currents is such as to carry the smelter smoke where it could do harm, that is, if other precautions were omitted. East of the smelter is the broad expanse of the Bay, with no settlement within fourteen miles, and it is in that direction that the wind will bear the smoke nine months in the year; but southward are the villas of Burlingame and San Mateo, where reside many wealthy people, and it is to protect them from a possible nuisance that all the precautions are being taken. A stitch in time saves nine, and it is in this spirit that the smoke-condensing arrangements have been designed. The result will be that while a large portion of the community is benefited by the establishment of a new industry, the others will have no ground for complaint. On another page we give a sectional elevation of the plant and with it a map of the Bay of San Francisco, indicating the exact locality of the site.

Gold Production of the World.

WE have been able to secure sufficient data to make a reliable estimate of the amount of gold produced in 1906. Of the total only 12 per cent is not based on actual statistics. The output of some of the countries of the world is not yet obtainable from official statements, but these sources of the metal happen to be of minor importance. In the preparation of the tabulated statement that follows, we have taken fine gold at $20.67 per ounce Troy and the pound sterling at $4.85, so that anyone desiring to convert the totals, either into ounces or pounds, can do so.

GOLD PRODUCTION OF THE WORLD.

	1905.		1906.	
North America:				
Canada	$14,610,395		$12,023,932	
United States	88,.80,700		96,101,400	
Mexico	1.,526,855—$117,317,950		15,847,880—$123,973,212	
Africa:				
Transvaal	100,890,058		119,212,937	
Rhodesia	7,180,177		9,821,087	
West Africa	3,172,027—	111,242,262	4,165,180—	133,199,204
Australasia:				
New South Wales	5,669,099		5,249,911	
Victoria	15,448,055		15,963,234	
Queensland	11,951,784		11,098,219	
Tasmania	1,520.072		1,253,615	
Western Australia	40,416,382		37,090,909	
New Zealand	10,193,514—	85,201,906	11,021,389—	81,677,277
Russia		22,291,600		24,000,000
India		11,655,100		10,694,077
British Guiana		1,637,685		1,641,031
Other countries		27,142,697		30,000,000
Total		$376,489,200		$405,184,801

The grand total is $405,000,000, an increase of nearly $30,000,000 over the previous year. It is noteworthy that the gain comes chiefly from Africa, where an increase of $21,000,000 is recorded; and of this, $18,500,000 is to be credited to the Transvaal. In that country the dividends also increased from $23,559,064 in 1905 to $27,816,536 in 1906, the total dividends paid since the South African war amounting to $97,523,650. Next in importance is North America, where there is an aggregate gain of $6,500,000, due wholly to the United States, which ranks easily first with a production of $96,000,000. The increase of $8,000,000 made in the United States is due to Alaska and Nevada, as explained in our issue of January 19. In Canada, the yield from the placers of the Yukon decreased from $8,327,200 to $5,600,000, while in British Columbia the output remained stationary at about $6,000,000. In Nova Scotia and Ontario the mining for gold is insignificant, when viewed in its world-wide aspect. While there is a diminution of $2,500,000 in Canada, Mexico exhibits an increase of $1,000,000, which is less than might have been expected, having regard to the energy with which Anglo-American capital has been applied to the mines of the southern Republic. Fully one half of the total yield comes from three mines in El Oro district. Turning to the antipodes, we find that the output of the States of the Australian Commonwealth and New Zealand shows a diminished figure, being $3,500,000 less than it was in 1905. The chief decline is in the leading State, namely, Western Australia, where $37,000,000 was produced as against $40,500,000 the year before. This is due to the slow exhaustion of some of the big mines, without a compensating growth of the smaller properties. Dividends, however, did not decrease heavily, being $9,661,500, or only $851,548 less than in 1905. The old districts of Victoria did well. In Queensland, the great Mt. Morgan mine continues to be an important factor. In New Zealand, the Waihi helped to make a slight increase, and the mines of the South Island contributed. Russia's yield is not yet definitely known, but it is expected to be slightly more than the year previous, for there has been a notable increase in the interest taken in the gold mines of Siberia, and the interruptions caused by the Japanese war have been overcome. In India there is a decrease of $1,000,000 or 8½ per cent. The gold comes wholly from the Kolar district, in the Mysore, from a group of mines that maintain a steady production. Among the less important gold-producing regions, there is a slight decrease in Japan, an increase in the Central American States, also in Colombia and Peru. On the whole, the dominant feature is the vast output of the mines at Johannesburg, in the Witwatersrand district of the Transvaal, and it is probable that this contribution to the wealth of the world will increase for a few years longer before it begins to reflect the exhaustion of the mines, the resources of which are measurable. In North America there is a tremendous speculative activity in gold mining and a part of this will take productive form, so that, with large tracts of country still awaiting exploration, there is probability of an augmented yield. In Australasia, it will be difficult to balance the steady decline of the West Australian mines, unless new discoveries are made. The Russian output is likely to increase in 1907, while that of India will exhibit no great change, with a tendency to lessen. Other regions are being prospected and from them more gold will be won, with the possibility of important discoveries in South America. Therefore, 1907 ought to surpass 1906. The maximum gold production of the world has not yet been reached.

Personal.

G. D. DELPRAT is at Amsterdam.

CLAUDE T. RICE is now at Butte, Montana.

C. S. HERZIG is returning from Egypt to London.

J. E. SPURR is doing geological work at Leadville.

C. M. ROLKER is on his way to the Lena mine in Siberia.

JUAN FELIX BRANDES is on his way from Mexico to Paris.

JOHN A. PORTER, of Denver, was in San Francisco this week.

BERNARD HUNT has gone to the Gold Coast of West Africa.

ROSS B. HOFFMANN will be at Tonopah for the next few months.

WILBUR E. SANDERS, of Butte, has been on a visit to New York.

F. L. RANSOME, of the Geological Survey, has returned to Washington.

F. LYNWOOD GARRISON has returned to Philadelphia from Santo Domingo.

THOS. B. BASSETT is mine manager for the Belen Mining Co., at Cumpas, Sonora.

F. H. MINARD has been examining mines near Santa Lucia, in Sinaloa, Mexico.

G. W. MILLER is examining mines at Telluride, Colo., in behalf of an English syndicate.

JOHN M. CAMERON is now manager for the Butte Central & Boston Copper Co., at Butte.

GEORGE W. MCBRIDE is the new superintendent of the Sierra de Cobre mines at Cananea.

J. J. YECKEL is manager of the Central property, in the Taviche district, of Oaxaca, Mexico.

ALLAN A. DAVIDSON is on his way from London to Rio Janeiro, to examine mines in Brazil.

H. W. HAZARD is in charge of the Natividad copper mine, near Ocotlan, in Oaxaca, Mexico.

JOSEPH C. HOPPER has resigned from Charles Butters & Co., and has gone to England on a visit.

ARTHUR W. JENKS passed through San Francisco on his way from Montana to Riverside, California.

R. DE SALLIER, chief assistant of R. M. Atwater & Co., is back in Helena, after a business trip to New York.

LLEWELLYN HUMPHREYS has become advisory engineer to Gunn, Thompson & Co., of Salt Lake and New York.

JESSE F. WELLBORN succeeds the late FRANK J. HEARNE, as president of the Colorado Fuel & Iron Co., at Denver.

W. B. DEVEREUX has recovered from a long and serious illness. His sons are now in partnership with him at New York.

SAMUEL STEVENS has gone to Hahns Peak, in his capacity of manager of the Iowa-Hahns Peak Gold Mining Company.

WALTER J. MORRIS has been appointed superintendent of the cyanide plant belonging to the Octave Mining Co., in Arizona.

A. W. GEIGER, lately assistant to the manager of the smelter at Hadley, Alaska, is in San Francisco, on his way to Nevada.

CHARLES P. BOONE, of Berkeley, is leaving for San Sebastian, in Salvador, to take an appointment with Charles Butters & Co.

F. F. SHARPLESS, after doing work of inspection in Colorado, has gone to Oaxaca, Mexico. He will return to New York in June.

HOMER EMERSON, formerly superintendent of the Grey Rock mine at Butte, is now superintendent of the Boston & Corbin property.

R. H. BURROWS is examining mines in Chihuahua, Mexico, in behalf of the Kansas City, Mexico & Orient Railway Company.

L. M. KING is moving his office from Oakland to San Francisco. After May 1 he will be at Second and Minna St., San Francisco.

H. VINCENT WALLACE has returned to Nogales, Ariz., from the examination of mines at Guanajuato and other districts in Mexico.

ALBERT L. GREENE has resigned as chemist at the Deming smelter, and is now manager for the Santa Catarina Co. in Oaxaca, Mexico.

WALTER FITCH has been appointed mine superintendent of the Calumet & Hecla, JAMES MACNAUGHTON being, as heretofore, the general manager.

JAMES CHYNOWETH has resigned as superintendent of the Centennial and Allouez mines, in Michigan, and has gone to Globe, Arizona, to supervise work at the Superior & Boston Co.'s mines.

Obituary.

JOHN A. KEBLER, general manager of the coal operating department of the Colorado Fuel & Iron Co., died suddenly, at Trinidad, on April 12. His death was due to ptomaine poisoning, caused by eating canned salmon.

BENJAMIN SADTLER, a mining engineer well known in the West, dropped dead on a street at El Paso, Texas, on March 29, while on his way to Mexico from Denver. He was an accomplished man and for six years held the professorship of mining in the Colorado School of Mines.

Latest Market Reports.

PRINCIPAL QUOTATIONS FOR MINES.
San Francisco, April 17.

Argonaut	$4.80	Central Eureka	$0.97

Mining Summary.

ALASKA.

(Special Correspondence).—The Copper River & Northwestern railway is under construction from the tidewater terminal at Katalla, Alaska, through the Copper River valley, to the interior of Alaska, about 500 miles of railway line. A breakwater about one mile long will be constructed at Katalla. This road is one of the J. P. Morgan and Guggenhelm interests in Alaska, and will be built by the Katalla company, of which H. K. Rogers of Seattle is the president and general manager, and John Krey is the chief engineer. Contracts for the whole or any part of the work will be let immediately.

Seattle, April 13.

JUNEAU.

The strike situation at the Treadwell mines remains unchanged, and the United States troops from Fort Seward are close at hand and, if any trouble should arise, will be called out to protect the property of the company. The strike is general and there are barely enough men left to run the pumps.

The town of Douglas feels the effects of the strike keenly, as on account of the merchants siding with the operators, the miners are buying their supplies in Juneau, and many miners and their families are moving away. The charter for the Douglas Union of the Western Federation of Miners has arrived and the Union is determined not to recede from its demands.——The Rubicon Gold Mining Co. has sent a representative to the States to purchase a compressor and other mining machinery, for early shipment.

The latest report, though meagre, states that the strike has been ended at the Treadwell, with a victory for the operators, who will retain their black-list.

ARIZONA.

COCHISE COUNTY.

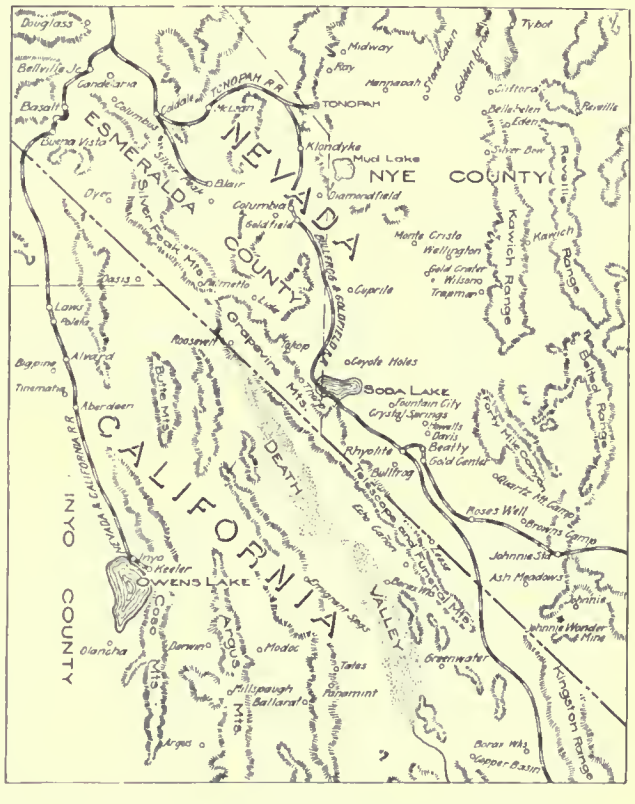
The leaders of the Labor Union in Bisbee have finally succeeded in precipitating trouble. At a recent meeting, attended by about 70 members, it was decided to appoint a committee to call upon the men at the head of the mining companies operating in the Warren district, and demand recognition of the Union. The operators refused to discuss the question, stating that Bisbee was an open camp, and there was no recognized union there. The next development was a circular, issued by the Union, calling upon the employees of the local companies to stop work at once. This circular contained no mention of any grievance, except that the mine owners had denied recognition to the labor organization. Following this action, there was a meeting of the mechanics employed by the various companies, at which it was unanimously voted not to stop work in sympathy with the striking miners. This includes machinists, engineers, pumpmen, and blacksmiths, and the resolutions adopted by the meeting prove that they are not in sympathy with this move on the part of the Western Federation of Miners, and as there are 130 mechanics, their action will bear weight.

In the two days following the call for a strike, 564 men drew their time, being divided among the different companies as follows: Copper Queen, 328; C. & A., 92; S. & P., 80; Shattuck, 44, and Denn-Arizona, 20 men. This is about 10% of the men employed in the district, but in addition to these, many men are laying off, awaiting developments, so that the total number involved is probably about 1,100 men, or one-quarter of the total force working in the district.——The reports of the Calumet & Arizona, and the Superior & Pittsburg mining companies for the year 1906, have been issued.

During the year the C. & A. produced 18,735, and the S. & P. 4,522 tons of copper. At the S. & P., 40,018 ft. of development work has been done during the year. The Cole shaft has opened oxidized ore at the 1,100-ft. level, on the Jessie Glencairn claim, and at the 1,000-ft. level on the Sunnyside claim, while on the Irish Mag claim of the C. & A. as much ore has been developed as has been stoped.

YAVAPAI COUNTY.

A Phœnix syndicate, associated with I. T. Hosey, has secured control of the Neiman and Crosby groups of claims in the Santa Maria district.——The Arizona Chief company is now in control of the group of claims formerly owned by G. C. Davis, in the Eureka district. A 50-ton Lane mill will probably be installed, and a pumping plant built on Burro creek.——In the Jerome camp it is expected that at least three new producers will develop this year. The Jerome Mines Development Co. continues to get encouraging results from its diamond-drill work.——The Arkansas & Arizona shaft is below the 200-ft. point, and proceeding rapidly, with the machine drills now in use.——A new hoist has been erected at the United Verde Extension.——The Jerome Verde company will put on a large force of men at once.——The shaft of the Verde Grande Copper Co. is down 80 ft. and the new hoist is being installed.——In the camps near the Humboldt smelter much activity prevails. The Iron King, McCabe, and Gladstone properties are daily shippers.——The force has been increased at the Oriental.——The 20-stamp mill is running at the Poland mine, although the developments in the tunnel were disappointing.——The Blue Bell and De Sota ship daily to the smelter.——



Map of the New Mining Districts of Nevada and California.

Two mills, the Tiger Gold and Lincoln, are running in the Crown King vicinity, and work is being pushed on the California-Benton, Peck, Gold King, Castle Rock, and Gazelle properties.——On the west side of the Bradshaw Mtn., the Big O'Brien mill is nearly completed; a mill is being built at the Black Rock; and the Monarch M. & M. Co.'s new mill is running satisfactorily.

CALIFORNIA.

AMADOR COUNTY.

The Lucas mine, on the Mokelumne river near Big Bar bridge, has been closed and all the men paid and discharged.——The Bunker Hill mill ran 20 days last month and produced $11,000. Four dividends have been paid since the beginning of the year.

CALAVERAS COUNTY.

The miners of the Penn chemical works near Campo Seco have struck. The men have been working 10 hours for $2.75, and the 120 men at the smelter also work under these conditions of long hours and small pay. This is one of the richest copper prospects in the State.

EL DORADO COUNTY.

The Eureka slate quarry company has been awarded the contract to furnish 40 cars of roofing slate for the Government building at Cheyenne, Wyoming. The company is also making regular shipments of slate to San Francisco. Improvements will be made at the quarry this summer, the principal one of which will be the extension of the cable tramway, which will have a total length of over four miles. W. J. Dingee is the owner, and Charles H. Dunton, the manager of the property.——The shaft of the Alpine mine, in the Garden Valley district, is flooded from the 300 to the 200-ft. level.——The mill at the Union mine is closed, owing to the excessive flow of water into the underground workings.——A force of men is re-timbering the lower tunnel of the Standard Unit mine.——The new compressor-building at the Sherman mine has been completed and the 100-h.p. compressor will be installed at once.——Engineers have just completed the examination of the Big Cañon and Forest Hill mines, in the Shingle Springs district, and their client, J. B. Menardi, may purchase the properties.

HUMBOLDT COUNTY.

(Special Correspondence).—H. DeC. Richards, manager of the Orleans Gold Bar Mining Co., has been at Orleans. This company is arranging to put the lower flat into the river with as great speed as possible, all the Camp creek water having been carried to the east side of the property under a head of 400 ft. at bedrock, with an open chute of 200-ft. head from ditch to penstock. Thus the company will have a good piping-head on about 600 acres of its best ground, without any further work.——The suit regarding Camp creek rights is still awaiting the decision of the Supreme Court; meanwhile, the company is mining on both sides of the property.

Orleans, April 9.

INYO COUNTY.

(Special Correspondence).—The discovery of an immense body of colemanite is reported, on the west side of Death Valley. The deposit is over 50 ft. wide in places and will yield about 20% borasic acid. The discovery was made by Clarence Neyman, an old pioneer of the district.

Greenwater, April 8.

NEVADA COUNTY.

The Black Bear mine on Deer creek, a few miles northwest of Grass Valley, is to be worked again, and the scheme is being financed by Sacramento men. This property has produced some good ore, and the shaft is reported to be in milling ore at the bottom.——There is a good showing in the No. 6 tunnel of the South Yuba M. Co.'s property, which is being driven to cut the copper lode which was exposed in some workings higher up the hill.——The Wide West claim, adjoining the Canada Hill on the east, has been bonded by J. T. Morgan to Crocker & Co., of Tonopah. The shaft is down 100 ft. and sinking will begin at once. ——The two-stamp mill at the Ironclad mine will be replaced by a 10-stamp mill, and a pipe-line will be laid and a 1,400-ft. ditch dug. Eastern shareholders have financed the undertaking.

The Belle Union mine, situated in the heart of the Grass Valley mining district, on the east bank of Wolf creek, will be worked again. This property adjoins the Norambagua, which was recently sold to Pittsburg capitalists. A corporation has been formed to handle the property, and work will be started at once.

TUOLUMNE COUNTY.

(Special Correspondence).—The rich orebody recently uncovered on the 1,100 level of the App mine has been cut into for 20 ft. and there is yet no indication of the opposite wall. The old Heslep workings, which were full of water, were successfully tapped a few days ago, and the water is gradually running out.——The Standard M. Co. is increasing activity at its group of mines, situated southeast of Tuolumne. Development work is proceeding at the Hardtack claim, with Wm. Scott as foreman, and last week a rich strike was made in the south adit. The vein is only 10 in. wide at this place, but is very rich. The mill will be started in about six weeks.——A new 5-stamp mill has been purchased from the Joshua Hendy Iron Works for the Ellen Winton mine and is expected to arrive within two weeks. ——It is reported that at the bottom of the Shawmut mine, 2,300 ft. deep, the vein is 20 ft. wide and assays from $15 to $85 per ton.——The shaft of the Clio, at Jacksonville, will be deepened as soon as the water has been pumped out.—— The pay of employees of the Providence mine has been increased 25c. per day, miners now receiving $3.25; timbermen, $3.75, and muckers and surface men, $2.75.——T. J. Brown, representing Nevada capitalists, has bonded the Sargent ranch, near Groveland, and will soon have a crew doing development work on mineral-bearing veins. The price to be paid for the property is $9,000.——Work is to be immediately resumed at the Kanaka mine, in the Groveland section. Geo. DeSallier will be superintendent.——The erection of a 10-stamp mill on the Garfield mine, situated near the Grizzly, will be commenced soon, the machinery and lumber now being hauled to the property.——The North Star mine, in which a large flow of water was encountered a few weeks ago, with the result that operations had to be temporarily stopped, is unwatered and development is again in progress.——It has recently been learned that the limestone in the vicinity of Springfield and Columbia contains gold. Assays have been made and the average showing was $2.90 gold and 10c. silver per ton.——Johnson Lane, formerly superintendent of the App mine, lately became foreman of the Confidence.——Active operations have been commenced at the Dondero placer mine, above Columbia, by the new owners.

Tuolumne, April 14.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—Based on the figures for the first three months, there is every reason to believe that the producing mines in the Cœur d'Alene will pay in dividends more than $7,000,000 in 1907. Seven companies disbursed $1,598,500 from January 1 to March 30, as follows: Federal M. & S. Co., $510,000; Bunker Hill & Sullivan, $540,000; Hercules, $228,000; Snowstorm, $140,000; Hecla, $100,000; Success, $20,000; Monitor, $9,500. The Snowstorm and Monitor are copper mines, the Success produces lead and zinc, while the others are lead-silver propositions. Several other mines are to enter the dividend-paying class, among them being the Black-Cloud-California, operated by the Pittsburg Lead Co., which, it is reported, earned $40,000 in March. Another is the Stewart, which is in ore. The Charles Dickens, which has just installed a compressor, should also join the ranks in the near future.—— Strikes of good ore are reported from various mines in the district. The latest is the Gold Hunter, near Mullan, where, it is said, an ore-shoot was encountered in the lower tunnel, 3,000 ft. from the portal. The mine was one of the earliest producers in the Cœur d'Alene, and has paid big dividends. The ore is richer in silver than in other large producing mines of the district. During the last three or four years it has been worked intermittently. The concentrator did not make a good saving, so it was altered, improved machinery being installed 18 months ago. The new mill gave satisfaction, but the company has been much hampered during the summer and fall by lack of water. The strike will mean much to the Mullan district, which is working more miners than any other portion of the Cœur d'Alene. The mine is owned by Chicago capitalists, and is run by Spokane electric power.—— Reports are persistent that the Hypotheek mine, near Kingston, is to be sold. The property consists of seven claims, and some work has been done. Ore has been uncovered in the lower workings, but no shipments have been made. In the drift run from the bottom of the winze two narrow ore-shoots were opened; one was 18 in. wide and 20 ft. long, while the other was eight inches wide. This was at a depth of more than 400 ft. below the apex. Ore has been disclosed in other levels. —— Accidental discovery of ore in an abandoned mine has just been made by F. J. Martin, near Osburn, on the property of the Rhode Island Mining Co. The mine had an excellent surface showing, and the vein was encountered 300 ft. from the mouth of the tunnel. Shortly after this the property was abandoned, and nothing but the necessary work has been done on it since.—— James F. McCarthy,

manager of the Hecla mine, announces that the output of the property up to Jan. 30, 1907, was $4,500,000. The mine produced $1,354,000 in 1906, the aggregate value of 16,692 tons of concentrate and shipping ore. The company is installing a new hoist, the vertical depth of which will be 2,500 ft. It will be operated by electricity.—— Reports are that the Hercules mine, at Burke, has tapped a rich orebody in No. 4 tunnel. This is the lowest tunnel, and was started a year ago. It has now been driven 2,000 ft., and it is necessary to proceed 2,000 ft. more before the main lode is encountered. The strike was unexpected.

Spokane, April 12.

NEVADA.

CHURCHILL COUNTY.

(Special Correspondence).—Development is progressing on the main lode of the Nevada Hills property, and the operating force has been increased. The ore continues high-grade and large quantities are being taken out.——A shaft 4 by 7 ft. is being sunk on the Fairview Clipper and has encountered a vein carrying gold and silver, and running $25 per ton. The shaft will be sunk to a depth of 100 ft. before any cross-cutting is done. E. Murphy is the superintendent.——On the Ida group development is still progressing and samples of the ore assay well. The main tunnel is 25 ft. from the vein, for which it is driving. Shaft No. 2 is down 40 ft. in good ore, and when the 75-ft. level is reached, a cross-cut will be run to the vein. Shaft No. 3 is down 12 feet.——Shipping ore is being sacked at the Dromedary Hump mine, and new territory opened up. The new shaft is being rapidly sunk, although the non-arrival of the new hoist has hindered proceedings. This property is, after the Nevada Hills, the foremost in the district, and is employing a large force of men.——The Fairview M. & L. Co. is sinking a shaft on the Golden West property. The shaft is down 18 ft., and some fair-grade ore has been encountered.——The main shaft on the Empire State holdings is down 26 ft., and will be sunk to a depth of 66 ft., from which point a cross-cut will be run to the lode. The tunnel is in 150 ft., and has uncovered a promising vein.——Some good ore has been uncovered in the Hot Onion shaft and the management is greatly encouraged. The mine is still a prospect, but development is being vigorously pushed.——Several men are engaged in sinking the shaft on the Fairview Reliance property, and some excellent quartz has been encountered, samples running high.

Fairview, April 11.

WHITE PINE COUNTY.

The new stock exchange has opened in Ely.——A $10,000 payment has been made to F. S. Pheby on the Velvet group of claims purchased by Harry Darlington for the Manhattan Ely Copper Co.——The shaft of the Nevada Con. Stock Co. at Cherry Creek is down 60 ft. and will be continued to the 250-ft. point. J. W. Walker is the manager.——The Nevada-Walkover company has acquired a group of ten claims six miles west of Cherry Creek. A hoist will be installed.——A good body of ore has been struck at the 300-ft. point in the Mary Ann tunnel at Cherry Creek. P. H. Cannon is in charge.

BRITISH COLUMBIA.

The following is the tonnage of ore produced by the Rossland mines for the week ending April 6: Centre Star, 1,930; Le Roi, 2,695; Le Roi No. 2, 490; White Bear, 70 tons. Total for the week, 5,185. The new 650-h.p. electric motor of the Centre Star was started, and will be run for a week without a load, and then will be hitched on to the compressor that is now being run by steam. The motor from the War Eagle is being installed and will act as a helper to the larger motor that has just been started. The shaft has reached a point 70 ft. below the 14th level, and is being pushed toward the 1,500-ft. point. Development continues on the Idaho, and some ore is being mined from the glory hole.——At Le Roi, the hoist is in place on the Spitzee, and the mine is unwatered and will be cleaned out, and machine drills will be put in operation. In the main shaft of Le Roi, a station and pocket are being cut at the 1,650-ft. level, and a drift will be driven to connect with the winze workings.

At the Trail plant of the Consolidated M. & S. Co., 5,518 tons of ore were received during the week ending April 6. In addition to the ore sent from the Rossland mines, the following contributed shipments: Snowshoe, Phœnix, 728; St. Eugene, Moyie, 267; Lone Bachelor, 11; La Plata, Kokanee, 101; Iron Mask, Kamloops, 29; Beatrice, 28; Riverside, 24; and Ottawa, 21 tons of ore.——The Northport smelter is running regularly on ore from Le Roi mine.

The shipments from the Boundary mines during the same week were: To Granby smelter, from Granby mines, 18,879 tons; from Emma, 280. To British Columbia Copper Co.'s smelter, from the Mother Lode, 2,200; from Snowshoe, 520; from Emma, 340; from Morrison, 30 tons of ore. To the Dominion Copper Co.'s smelter, from the Brooklyn, 1,600; from Rawhide, 1,620; from Sunset, 800; and from Mtn. Rose, 105 tons of ore. To the Trail smelter, from Snowshoe, 1,030; from Providence, 30; from Elkhorn, 20 tons. To the Nelson smelter from the Emma, 40 tons. Total shipments for the week, 26,017 tons. In comparing the shipments and smelter receipts in southeastern British Columbia, the following table of shipments by districts is useful: Shipments from east of the Columbia river, 2,101 tons; Rossland, 5,185; Boundary, 27,134. Total for the week, 34,769 tons of ore.

The smelter receipts for the week ending April 6 were as follows: Grand Forks, 19,159; Greenwood, 3,090; Boundary Falls, 4,125; Nelson, 183; Trail, 5,518; Northport, 1,087; Marysville, 600 tons of ore. Total for the week, 33,762 tons.

It is reported from Boston that the Dominion Copper Co. will soon retire $175,000 of its outstanding issue of 6% bonds. The total issue was $1,000,000, but as the company now has available in its treasury about $700,000, a dividend will probably be declared as soon as the addition to the smelting plant is finished. With this new capacity, the company should be able to produce 6,000,000 lb. of copper per year, at a cost not exceeding nine cents per pound.——The Elkhorn mine is again on the shipping list, sending a carload of rich silver ore to the Trail smelter.——The cross-cut from the bottom of the 200-ft. shaft of the Grayhound mine, at Deadwood, is in about 80 ft. and is nearing the vein.——A carload of new machinery has arrived at the Snowshoe mine, including two small motors that will be used until the 400-h.p. motor is installed.

MEXICO.

CHIHUAHUA.

The Porvenir Mining Co. reports satisfactory progress on the Porvenir and Dudosa properties. On the former, there are two shafts, 200 and 100 ft. deep, and on the latter, a 115 and an 80-ft. shaft. N. P. Wilson is the manager.——The aerial tramway, and the railroad to connect it with the M. C. railroad, being built by the San Toy Mining Co., of Santa Eulalia, will be running by May 1. The tram from the mines to the foot of the mountain will be four and one-half miles long, with steel supporting towers. This company will soon begin the construction of another tramway a mile long, from the Galeana mine to the Central mine. J. P. Hutchinson is general manager for the company, and C. H. Wickham is construction engineer.——The Lewisohns, who recently purchased the Parcionera mine at Santa Eulalia, have not sent a new manager, and Charles Qualey is still in charge.——The famous old Rosario silver and gold mine at Guadalupe y Calvo is under option to a London company, which is unwatering the mine. For five years that property has been under option to Charles Clark. The Independence M. & M. Co., which has been operating in the Guachinango district of this State for several years, has been reorganized under the name of the Maseota Copper Co. The promoters are Minnesota men.——The furnace of the Lawson-Page interests, at El Moral, is treating 15 tons of cinnabar ore per day, and regular shipments of quicksilver are made to Ameca. This company's custom reduction plant on the San Gerónimo hacienda in the Maseota district will be operating within two months.——W. M. Matthews of Ezatlán, has started the development of the Palos Verdes group of 21 claims on the Santiago river near the Valenciana crossing. The property was formerly worked by Mexicans.

COAHUILA.

A company has been formed, with a capitalization of $1,000,000, to exploit the coal deposits on the Hacienda de San Blas in this State.

Special Correspondence.

Denver, Colorado.

Treatment Rates at Cripple Creek.—Competition is Useful.—Pot Roasting.—Zinc Ores at Rico.—Drainage Adit Specifications.

The commencement of operations by the Golden Cycle mill at Colorado City has caused a readjustment of treatment charges in the Cripple Creek district. The decrease made by the Golden Cycle management was met by a further reduction on the part of the American Smelting & Refining Co., so that the latter's charges remain lower than its competitors. The decrease in the output of ore from the lower levels of the mines at Cripple Creek, due to the present trouble with water, and the opening of more than one mill to treat the oxidized ore, is undoubtedly the cause of the shut-down of the Union mill at Florence. The United States Refining & Reduction Co. is diverting all its ore to the Standard mill at Colorado City, and whether the supply will increase enough to cause the speedy re-opening of the Union mill is a matter of some doubt. The Homestake mill, at Cripple Creek, after a month's run, announces that it has met with unqualified success, and has operated at a profit on ores of a grade slightly lower than $3. The other mills, now in process of construction, which are designed to treat oxidized ore, stimulated by this announcement, are hastening their preparations, and will soon be in readiness to begin work. In regard to poor sulphide ores, it is impossible to send them to points where coal is cheap, because of the freight charges. Similarly, it is not practicable to bring coal for roasting purposes to mills built near the mines, because of the high cost.

It is announced that the American Smelting & Refining Co. has introduced the Huntington-Heberlein process into all its Colorado plants. This process consists in first subjecting the ore to a partial roast in Godfrey, or similar furnaces, mixing with a proper quantity of lime, and then completing the de-sulphurization by blowing air through the mixture in hemispherical pots, known as converters. As modified by this company, instead of using the lime, raw Cripple Creek ore is used to mix with the partially roasted ore, with as good success as in the former method. The sulphur in the ores is reduced from about 40% to 6 or 7%. But by omitting the use of the lime, the essential feature of the Huntington-Heberlein process, namely, the action of the lime as a de-sulphurizer is eliminated, and the process becomes practically a kiln-roast conducted in the apparatus devised for the Huntington-Heberlein process. The next step to be logically taken would be the elimination of the preliminary roast, as in the Savelsberg process. The process as so modified would differ little in principle from pyrite smelting, but in this case the heat developed by the oxidation of the sulphur is only sufficient to sinter the mass, and not to fuse the charge. Naturally, the reactions that take place on fusing do not appear in the converting process. These reactions are brought about by the subsequent fusion in the blast-furnace. Such a process might then be regarded as pyrite smelting in two stages, thus securing the lower temperature throughout necessary to prevent excessive loss of lead.

The construction of a concentrating mill and smelter to treat the low-grade zinc-lead ores of the Rico district is to be started in the near future. While the details of the milling process to be followed are not yet known, it is said that it is similar to the one now in operation at Broken Hill, Australia.

The specification for the new drainage adit at Cripple Creek have been made public, though bids have not yet been advertised. The specifications provide for an adit 7 by 10 ft. in the clear, which must be driven at the rate of at least 300 ft. per month, all necessary timbering is to be done by the company, and the machinery is also furnished, the contractor supplying power, labor, and supplies. Employers' liability insurance is to be carried by the company, the contractor to pay the premium on this, and also furnish a bond for $20,000 to cover possible debts and liens.

Salt Lake, Utah.

Consolidation of Companies.—Dividends.—Labor Troubles at Park City.—Silver King Merger.—New Mills at Bingham.

Shareholders of the Star Consolidated Mining Co. have been called to meet in special session on May 8 to discuss the matter of effecting a coalition with the Black Jack Mining Co., both operating in the Tintic district. It is proposed that the latter shall absorb the Star Consolidated giving its shareholders one-half of the capital stock of the reorganized Black Jack Co. The present capitalization of the latter is 300,000 shares; but it is to be increased to 1,000,000 shares.——The May Day mine at Tintic has been closed down temporarily. It is said that the new management is dissatisfied with the conditions of the smelter contract under which the former management operated. There are rumors of consolidation with the Uncle Sam; this company has made a shipment of ore from the body opened recently on the 800-ft. level, the controls returning 36% lead, 12 oz. silver, and $1.50 in gold. Thirty-two tons netted $1,027.

Dividends have been declared this month by the Beck Tunnel Con. Mining Co., for $40,000; Grand Central, $25,000; Bullion Beck, $10,000; Utah, $3,000. The Ontario and Daly-West mines at Park City were closed temporarily last week on account of slight labor difficulties, but these were adjusted without serious loss to either employer or employee. The matter of the time of going on and off shift entered into the controversy. The differences with the men employed in clearing the Ontario drain adit, however, have not been settled. The completion of the deal for a coalition of the Silver King and several adjoining properties under the name of the Silver King Amalgamated Mines Co. is expected at any moment. The Odin mine is likely to be included in the merger.

The Phœnix vein has been cut at a distance of 1,200 ft. from the portal of the lower adit in the Phœnix mine, at Bingham. A large tonnage of high-grade lead ore was extracted from this vein in the adit 200 ft. above. A small mill is operated on the property.——The addition recently made to the mill of the New England Gold & Copper Co. is being used and the plant is now operating at double its former capacity. The management expects to turn out at least 14 cars of concentrate monthly with present facilities and, in addition, market from three to five cars of crude lead ore. Two cars of copper ore were sold last week.——The new mill of the Markham Gulch Milling Co. is nearing completion. It will be in operation by May 1 and will treat ores of the Utah Apex and Utah Development mines.

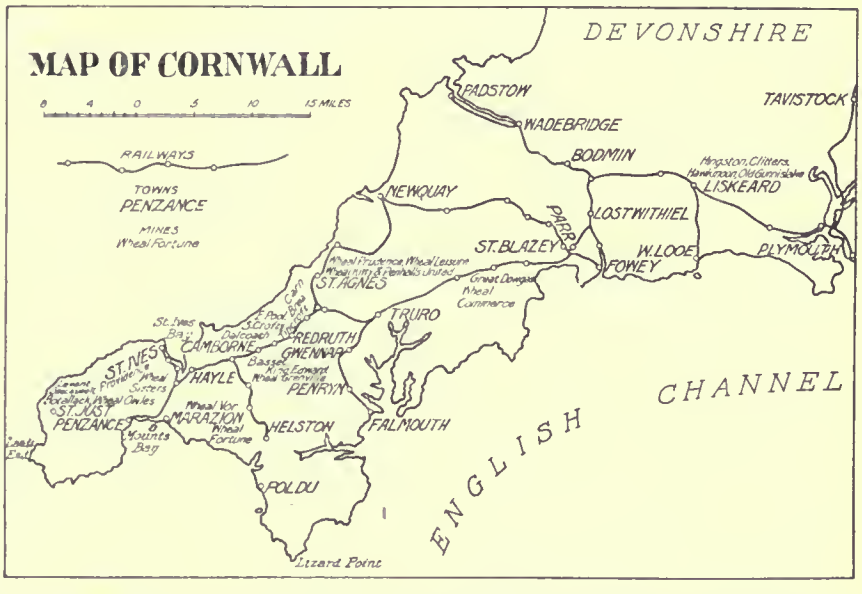
Development work has been resumed in the Scottish Chief mine near Alta.——The Ophir mine at Stateline will be started up about May 1. The property has been shut down for several years and is equipped with an expensive mill, which was not suited to the ore.——Through traffic has been resumed on the San Pedro, Los Angeles & Salt Lake Railroad. The construction of the Caliente & Pioche branch of the road will be started, it is said, within one week or ten

days.——The ore and bullion settlements reported last week through Salt Lake banks amounted to $485,000.

London.

The Share Market.—Big Pumping Engines.—Deep Mining in Cornwall.—Successful Development.—Mining in Siberia.—Banket in West Africa.—Egyptian Gold Mines.—Stratton's Independence.—Treatment of the Big Dump.

In reviewing the mining account just concluded, a City report states that usually small and irregular, but chiefly downward, changes are shown in the list of shares. So far as mining securities are concerned, the account has been productive of little fresh business, apart from the leading diamond and copper descriptions (which have been lively enough at times); but that it is explained partly by the fact that barely ten working days have elapsed between the two carry-overs, and partly by the general market demoralization, which has had the effect of increasing the public indisposition to enter into commitments, more especially with the Easter holidays looming ahead. The dealings in the principal copper and diamond shares, which have provided the mining department with its outstanding features for months on end, were largely on account of continental operators, mainly French, and both in Paris and Berlin liquidation upon a substantial scale has latety been in progress, with unsettlement and depreciation as consequences. In view of the general market conditions, Kaffirs may be said to have held their ground remarkably well. They have been assisted by the excellent results reported for February, by the several discoveries in the east-central portion of the Rand, aud by the steadily growing impression that the industry Is going to be fairly treated by the new Transvaal legislature.



The starting of two pumping engines during the month is a welcome sign of the renewed activity in Cornish mining. The christening of a powerful 80-in. engine at Condurrow United was an event of importance even in a district which can boast of containing the leading mines of the present day in Cornwall. This engine, although built for West Chiverton in 1886 was found to be little worn when it was again transferred a few months ago from Gwennap United to Condurrow. Mr. Peter Watson, who presided at the luncheon which followed the christening ceremony, said he had known the great Condurrow mines intimately for over half a century, and the great thing he had always borne in mind was the fact that the sett was situated in the centre of a series of successful mines. To the north was Dolcoath, which was always to the fore and really still looked like a property in its infancy. Then Basset mines lay to the east and from those mines enormous quantities of tin and copper had been raised. Southward lay Grenville, which had now been placed upon a satisfactory financial basis and started upon a career of prosperity. Grenville was still in its infancy and had great possibilities for the production of mineral. Condurrow mines were in the centre of a rich district, and if there was one sett more certain to be rich and prosperous than another, it was the sett upon which they were standing. When Condurrow worked last it was equipped with an engine of 36-in. cylinder and that sufficed to pump water from the 300-fm. level. But the present proprietors had determined to install an engine of sufficient size to undertake even greater duty. With such an engine installed the company need have no anxieties as to the future. Mr. Angwin, the engineer, said the engine was one of the finest in Cornwall and would lift 110 tons of water per hour. Mr. John Tonkin and Prof. Laws, of the Camborne School of Mines, gave it as their opinion that taking every factor of cost and duty into account this Cornish engine has advantages over the electric pumps in use in England and France, for the work to be done at Condurrow; an opinion shared by Mr. Negus, the former superintendent, as the result of visits to the North of England and Welsh mining districts. This opinion appears also to be shared by the consulting engineer of the Basset Mines, who is reported as stating that he had gone into the question as regards Basset and found that electric pumping at that mine would cost about £9,000 per annum at least more than the present cost.

The Dolcoath executive has been taken to task for the delay in the sinking of Williams shaft, which was one of the main purposes for which working capital was subscribed by the public when the prospectus of the limited company was issued in 1895. It is thought probable that pressure may be brought to bear on the directors by the new landlords for the resumption of this important part of the development program. There has been a rise in the shares of East Pool on the discovery of a fine lode of tin at the 290-fm. level. In character and size it is said to be the best bunch of tin revealed in this property for a very long period; and as it is in the bottom its importance cannot be too highly estimated. The importance of deep mining is further exemplified at Grenville; in the bottom of Fortesque's a good lode has been cut, and it is larger and richer than the lode in the upper level. In the shallower levels of Grenville there are some rich deposits of copper. The Cornish Consols are operating at South Phœnix, a celebrated mid-Cornwall property, and it is announced that by reason of its favorable geographical position Phœnix has been selected as the future testing ground for all new mining machinery and plant with which the group of pioneer companies purpose to deal. The water has been pumped below the 150-fm. level of the Hingston section of Clitters United and here again the bottom part is the richest. The secretary states that "the exploratory work so far done shows this level to be decidedly better than we have previously unwatered, both for tin, wolfram, and copper values."

Siberian stocks of all kinds are dull on the market just now and reports from the mines are of a meagre description. The manager of Orsk Goldfields reports that for

the four weeks ended February 23, the total output of retorted gold was 1,067 oz. from 2,664 tons of ore. Of this amount 760 oz. were obtained by crushing 1,393 tons of tributer's ore, 25 oz. were obtained from the Suvunduk and Siberia alluvial claims, and the balance, 282 oz., from crushing 1,271 tons of the ore that was purchased from the lessors of the property. The total revenue to the company from all sources for the period in question, after deducting the working expenses of the mills, is estimated at £1,861. Owing to the continued severity of the weather, it is anticipated that the water supply will be insufficient to enable more than four of the Chilean mills to be worked until the thaw sets in.

Among West Africans the 'banket' descriptions, which have remained steady throughout the long period of market inactivity, are said to have begun to attract attention again. The reason for this is to be found in pending developments at the mines. The Abosso mine, with 30 stamps, has been producing gold to the value of over £150,000 per annum for a working profit of nearly £60,000, but the annual production will apparently soon reach a quarter of a million sterling, as the 20 additional stamps, which it has just been decided to erect, are expected to be shipped shortly and to be in full swing by the end of June next.

Regarding Egyptian gold mining a correspondent asks: Does the Egyptian section of the mining market really exist? That it did so at one time is well known, but that unexercised option of J. B. Robinson on Nile Valleys seems to have been the beginning of the end. There is a scarcity of news from Egypt with reference to those gold mining ventures whose names are pretty well known over here. It is presumed that work is still going on, but in many cases it must be after a desultory fashion, because the working capital, if not already exhausted, must be on the point of running dry, and in the present condition of affairs the raising of further funds would appear to be an absolute impossibility. That there is gold in Egypt admits of no doubt, and at one time it looked as though the Land of the Pharaohs would take a prominent place in the gold production of the world. It is to be feared that the original hopes of many have been falsified by events. The promoters almost unanimously blame Lord Cromer for the rigid manner in which he has supervised the formation of companies, and the numerous provisions (some of them of rather a drastic character) that promoters have had to observe before permission could be granted for the commencement of mining. On the other hand, Lord Cromer has taken up the position that only mines sufficiently developed to prove their worth should be allowed to pass into the hands of companies.

Stockholders in Stratton's Independence will welcome with satisfaction the announcement just made by the directors that the study of the problem of the dump and low-grade ore treatment, which had occupied the attention of various specialists on the subject for a lengthened period, has now been finally brought to a satisfactory conclusion by Mr. Philip Argall's investigations. The directors inform the shareholders by circular that the consulting engineer, Mr. Argall, has cabled the following report:

"Dump average may be taken as $3.60 per ton of 2,000 lb. Expect to recover about 70%. Estimated cost of treatment per ton, $1.50. Estimated profit per ton, $1, contingent upon milling 10,000 tons per month. Would suggest immediate erection of mill not less than 10,000 tons. Total estimated cost of construction amounts to $200,000 approximately. By this treatment I propose to deal also with the mine low-grade ore, and 50 tons per day high-grade ore plant is included in the estimate."

The directors point out that in Mr. Argall's plan of operation three sources of profitable milling are provided for, namely:

(1) The ore from the dump on which 600,000 tons are estimated as available.

(2) The utilization of the masses of low-grade ore in the mine hitherto unworkable, sufficient in the general manager's opinion to keep a large plant running for many years.

(3) The anticipated continued output of high-grade ore, the provision for which is up to 50 tons per day.

In their circular the directors further state that from this milling scheme, it would seem most probable that without including any new discoveries of ore beyond the area of the Company's property already explored, the mine may be counted upon to earn a substantial profit for a good many years, and while pointing out that the proposed outlay is well within the Company's own financial resources, they are of opinion that the money could not be better employed.

Johannesburg, Transvaal.

The Unemployed.—A Bad State of Affairs.—Dutch in Control of New Parliament.—Increase of Crime.—Annual Meeting of Chamber of Mines.—President's Speech.—Output of Gold.

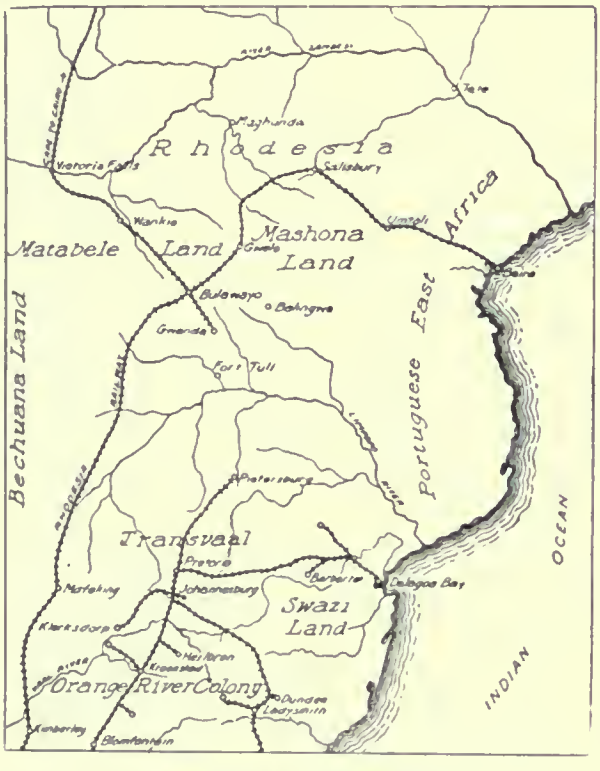
The problem of the unemployed is far from being settled. The mine managers have stated that they have no more room for white men, and the different municipalities find it impossible to put on any more. The Government has commenced road building in the Western Transvaal, but the wages offered to white men are low, so that few of the unemployed have applied for work. A silent procession of the unemployed parades the streets of Johannesburg several times a week. At the head of the column the destitute women and children ride in trolleys and behind the wagons in lines of fours march the unfortunate men who are 'hard up.' After tramping through the principal streets of Johannesburg the procession walks back to the camp, on the outskirts of the city. It is an unfortunate state of affairs. These people must be kept alive somehow, and the great danger is that they will live on charity so long that a number of them will become paupers, and lose their desire to exert themselves. Everyone feels the problem keenly, but as yet no solution has been found. The idea to send the destitute Australians back to their country, where there is plenty of work for them, is a good scheme, and it is to be hoped that it will be carried out.

After some days of waiting we now know who is to make up the first cabinet of the Transvaal. It is almost entirely a Boer ministry, and in this new British Colony the Dutch anguage will be of more importance in the Parliament than English. Still it is not thought that the Boer party will do anything rash. The general feeling is that the industrial outlook is not altogether bad, but that the political future, as far as the British party is concerned, is rather hopeless. Het Volk, the Dutch party, has obtained such a firm grip of affairs that it is unlikely the Progressive, or British, party will ever get into power. We are all waiting with bated breath for a speech from General Botha, the new Premier, who is expected to make a pronouncement of his party's policy, next week, at a dinner to be given the cabinet in Pretoria.

This is the time of year when reports of all kinds roll in. The report of the criminal department shows an unfortunate increase of crime in the Transvaal, especially along the Rand. As a rule a period of distress is found to produce an increase in crime, and the depression in the Transvaal during the past year accounts for much of

it. Unfortunately many white men out of work find the attractions of illicit gold-dealing and illicit liquor-trading too strong to be resisted. The selling of liquor to natives, against which there is a most stringent law, has grown during the past year, as has the illegal supplying of opium to Chinese. For a time the crime committed by Chinese was very high, but this has been greatly reduced in the past month or so.

The annual meeting of the Chamber of Mines was held a few days ago, and in his address the president touched on every topic affecting the industry at the present time. Most interesting were his remarks regarding Chinese labor on the Rand. If the thousands of coolies who are desirous of signing again for three years are allowed to do so, there can be little doubt that the Rand will have one of the finest forces of rough laborers in the world. The efficiency of the coolies has steadily improved, so that today mines with Chinese labor are working just as cheaply as with Kaffir labor. The following comparative figures from the Simmer & Jack, working with coolies, and the Robinson Deep, working with natives, are interesting:



Map of the African Goldfields.

	Chinese on the Simmer & Jack.	Natives on the Robinson Deep.
Average number employed	4,014	8,695
Average number working	3,753	2,274
Total number of shifts	289,275	184,078
Compound expenses (including time-office, but exclusive of Chinese wages), per shift, pence	10.930	8.647
Labor supply – procuring, repatriation fund, passport, fees, etc., per shift, pence	5.789	5.312
Wages per man per shift, pence	20.953	21.467
Total, pence	37.672	35.426

To refute the false statements made with such persistence by the Liberals, that the white managers are such tyrants that the coolies hate them, the president in his speech draws attention to the fact that on several mines the coolies have of their own free will presented the compound managers with gifts, to show their appreciation of the treatment they had received. On the whole the relations between the white bosses and the coolies are now satisfactory. The miners work with Chinese in preference to Kaffirs.

As was to be expected, the returns for February show a big drop in the output over January. Not only was it a short month, but the Chinese New Year celebrations which lasted three days hung up the mills on Chinese mines for two days or more. The total output for the Transvaal works out at 493,542 oz., valued at £2,096,434. This is a decrease of 44,096 oz., valued at £187,307, as compared with January. The value of the Rand output was £2,021,006, or 475,785 oz., leaving the outside districts to account for 17,757 oz., valued at £75,428. The largest producer for the month was the Robinson mine, with 21,514 oz.; next comes the Simmer & Jack with 21,100 oz. The number of coolies available for mines on February 28 was 53,736.

Leadville, Colorado.

Monthly Output.—Geological Report.—Special Maps.—Extension of Productive Area.—New Enterprises.—Reopening of Old Mine.—Activity on Rock Hill.

During the month of March the Leadville district produced approximately 75,000 tons of ore, which was distributed among the different smelting centres as follows: American Smelting & Refining Co., 60,000 tons; Colorado zinc mills and smelters, 12,000, and the Salida smelter, 3,000 tons. The lead smelters were not able to handle all the sulphide ore offered, which accounts in part for the failure of the district to reach its normal monthly production.

A publication of unusual interest to mining men generally and to Leadville mining men especially, will appear in a short time from the United States Geological Survey. The new publication will be a report supplementing the classic monograph formerly prepared by S. F. Emmons. A large portion of the district has been exposed by adits, shafts, and general development work since Mr. Emmons studied the district; consequently an exact portrayal of the geological formations is now possible. The report is being prepared by Mr. Emmons and J. D. Irving, formerly of Lehigh University, and recently appointed to a professorship at Yale. Among others, three special sets of maps will appear in the report; one of these will be devoted to the 'down town' district, which is now complete; a second, styled the Small Hopes section, in the vicinity of the Adams, Castle View, R. A. M., Mahala, Greenback, Wolftone, and other adjoining properties; and the third will embrace the region in the vicinity of Iron hill and the route of the Yak tunnel across Iron and Breece hills.

Until recently the district has been divided in the popular mind into 'inside' and 'outside' ground, referring in the former case to unproductive or questionable territory, and in the latter case to the area already mined and proved. The 'inside ground' referred to that which is bounded on the north by Big Evans gulch, on the east by Ball Mtn., on the south by Iowa gulch, and west by the city limits. It was within these limits that the early day bonanzas were developed. But the developments of the past few years have demonstrated that this area covered only a portion of the ore measures. The favorable parts may now be extended to a much greater area, in fact to all the territory that includes the lime and porphyry contacts or either of these with the quartzite formation. For example, the Boulder, Mammoth, and other properties lying to the north, have opened ore deposits, proving that a very valuable territory lies as far north as Prospect mountain.

One of the new enterprises on Rock hill, from which much is expected in the near future, is the Ovens Mining & Leasing Co., whose operations are under the management of Thos. Ovens. This company will operate under lease the Alhambra placer, which side-lines with the

Crescentia. A new shaft is being sunk and it is now over 300 ft. deep. From the available information, another 300 ft. will penetrate the lime-porphyry contact, where the management expects to expose the ore-shoot encountered by the Crescentia. A modern plant of machinery has been installed to push the work and as yet no body of water has interfered with progress. Another property on Rock hill, the Raven lease, under the management of Wm. Bowden, is making a good record. The lessees are shipping 25 tons of ore daily.

The Midland Mining Co. has recently secured the Mansfield group of claims, and active development work, under the management of F. J. McNair, has commenced. In the early days, a shaft was sunk on this property to a depth of 700 ft. An adit is being driven from Iowa gulch to tap the bottom of the shaft. The water problem was found to be a serious one, and this method was most practical for drainage. A plant of machinery will be installed later.——A shaft sunk on the Leo ground over 15 years ago opened a body of zinc-silver ore, but the zinc product at that time was unprofitable. Lately the shaft has been unwatered and development work indicates the ore-shoot to be a continuation of the mammoth Moyer ore-shoot, which, if correct, will assure the future of the property. The evidences of a big body of ore at the present time are most encouraging.

Butte, Montana.

Views of Mr. Thayer.—Activity in the Corbin District.—Butte & London Co.—Butte & Milwaukee.—Colusa-Leonard Extension.—Some Good Samples.—Misunderstanding of Their Character.—Samples Do not Make Mines.

Ben B. Thayer, assistant to the president of the Amalgamated Copper Co., is engaged in making an examination of all the mines and other properties of the various subsidiary companies of the Amalgamated. This company has many improvements under way and Mr. Thayer says the output in the next 12 months will be the heaviest in the history of the Butte district. The Washoe smelter is treating 10,000 tons of ore daily now, that being the full capacity. The Great Falls smelter is using about 4,000 tons and that plant is being enlarged so that it will be able to handle 5,000 tons per day. Development work in all the mines, he says, will continue on a greater scale than ever. Mr. Thayer, speaking about the metal market, said he could see nothing that could bring about a reduction in the price of copper for some time. "Copper prices are not made or controlled by a trust, but are regulated by the law of supply and demand," he said. "The present demand can not be satisfied by the present supply."

There is much activity in the Corbin district, 50 miles northeast of Butte, where the recently organized Boston & Corbin Co. is developing some properties. That company is employing 20 men and is making small shipments to the East Helena smelter. The ore is sulphide and is identical with the silver-copper ores of the Butte district. Since the advent of the Boston & Corbin Co. into the Corbin district a number of other companies have been organized and the owners of unproved claims are placing ridiculously high figures on their holdings. There are few producing mines in the district as yet. A company has been organized in New York to work an old mine known as the Silver King, which has been opened with an adit 1,000 ft. long. It is claimed that the Silver King yielded $125,000 worth of ore some years ago. The Daly group, in the same district, consisting of five claims, will also be worked. John Berkin, of Butte, has secured a lease and bond on the property and will at once unwater the workings. The pioneers in the Corbin district are A. H. S. Bird of Butte and W. S. McCornick of Salt Lake. They have been exploring a large tract of mineral ground there for five years or more. Their experts and engineers are confident that the property will develop into a good mine.

The Butte & London Copper Development Co. has adopted the contract system in shaft-sinking. Heretofore the company has done the work itself with day labor, but results have not been satisfactory. The bonus system was introduced a month ago, but it did not stimulate progress, and now a contract has been let to do the work. The company has been sinking its shaft for a year and it is nearly 1,000 ft. deep, but there are more than 500 ft. yet to be sunk. The contractor furnishes all labor, and the company provides material, power, and an engineer. The Butte & Milwaukee Copper Co. is making slow progress with its shaft on the Colonel Sellers claim, which is down only 180 ft. The company owns five claims in the district north of the North Butte mines. It has been working on the shaft nearly three and a half months, and its plant has a capacity for only about 600 ft., but it is said that a new plant of 2,000-ft. capacity is to be installed shortly, the machinery for it having been ordered. It is intended to sink the shaft deep enough to explore the four claims owned by the company. It will be at least several years before the ground is sufficiently tested, as it has been forcibly demonstrated that great depth is required to open mines in the outlying portions of the Butte district. A concern known as the Butte & New York Co. holds a majority of the stock of the Butte & Milwaukee Co., and it is through the New York company that operations are conducted. It has been announced that it was the intention later to exchange the new stock for the old, and by that promise threatened litigation was stayed. Now, however, it is stated by officers of the company that there will be no exchange at all.

The shaft of the Colusa-Leonard Extension Co. has reached a depth of nearly 590 ft. Progress has not been so rapid lately on account of the condition of the ground. The bottom of the shaft is in mineralized vein-matter, presumably part of the vein that was encountered several hundred feet higher in the shaft. From the stringers cut in the shaft some good samples were picked, from which assays as high as 9% copper have been obtained. Of course, these samples have not been taken from a commercial vein, and mining men take them only as being encouraging indications. The showing is satisfactory to the local management. Unfortunately, Eastern people that promote new copper companies, and people who buy stocks of new companies, generally know so little about mining that they imagine they have a mine when a sample of rock assays well, and men whose interests and enthusiasm outweighs their judgment sometimes encourage that idea. That has been the experience in Colusa-Leonard. When the encouraging conditions were encountered in the shaft some persons, and papers, published it as a 'strike,' conveying the impression that a great body of commercial ore had been opened and that dividends were already in sight. Such stories injure legitimate mining, though they may temporarily aid the sale of a stock. The stringers of ore in the Colusa-Leonard shaft, from which samples were picked and assayed, may come from a good vein, and they may not. In themselves they prove neither the one nor the other, and the problem cannot be proved until the shaft is sunk at least 1,500 ft. deep and cross-cuts are run. The country for miles about Butte is full of stringers and seams of ore, but not many of them have been developed into big mines.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Moore and Butters Filter.

The Editor:

Sir—Mr. Bosqui[1] has recently entered the discussion on the relative merits of the Moore and Butters filtering processes, and has criticized at some length my own contribution to that discussion.[2]

He justly says, that until a comparison of efficiency and operating costs is forthcoming no conclusion can be reached. He admits that the Moore process "may require less power," and seems willing to entertain the idea that it may be the cheaper to install. If we ignore the labor requirements which are the same in each case, namely, one man per shift to tend the filters, the remaining factors affecting the relative merits of the two processes are efficiency, maintenance, and repairs. To these Mr. Bosqui devotes his article chiefly, and develops an argument, from which he concludes that "the sum of advantages, in so far as we can estimate them, would seem to be on the side of the Butters-Cassel process, from whichever point of view we choose to take, whether that of a mechanic who is looking for the simplest mechanism, or of the metallurgist who is striving for the best net result and the lowest cost of operation."

An examination of Mr. Bosqui's argument, however, shows that he has simply marshalled together what he considers the advantages of the Butters process, and the disadvantages of the Moore process. This, it need scarcely be pointed out, is not the judicial method. He has laid stress chiefly on the stationary filter, and his argument tends to show that it is technically and commercially superior to the movable filter. I think a valid criticism of Mr. Bosqui's article is that he argues tendencies without estimating their quantitative effect, though really he has begged the whole question by saying "Obviously, to give the best results * * * there must be a uniform and quiescent condition of the filtering surface throughout."

If Mr. Bosqui's arguments demonstrate tendencies that are important in their effects, the results will show in the freedom from leaks of the filters, in the life of the filters, and in the efficiency of the wash. They can show nowhere else. It is worth while noting here, that the filtrate from neither process is fit for zinc-box precipitation without further clarifying. At the Combination mill the Butters-plant filtrate is pumped through an ordinary filter-press before going to the zinc-boxes. At Bodie the filtrate passed through a group of settlers in series, until a clarifying-filter set was installed. At the Liberty Bell, this latter practice was abandoned in favor of precipitating the clear decanted solution from the pulp-settlers, and returning the Moore-plant filtrate direct to the batteries without precipitation.

I have stated before that the Liberty Bell filters are being changed to a better type. The first of these were installed last July, and have been in continuous service since then without repairs. The indications are that they will last with but few repairs until the canvas rots. They should easily last a year and a half without much repair expense, and if they should do only this well, and then be renewed throughout, the cost per ton for filters would be only 1.2 cent.

As to the efficiency of the wash: At Bodie it was decided to wash to a cyanide strength of 0.15 lb. per ton of residual solution remaining in the cake next the canvas. After a deal of experimental work this was fixed as the economic limit; and after the Moore plant was in operation, it was regularly attained in practice, in a little less time than it took to form the cake.

At the Liberty Bell, the strength of the solution coming from the filters in wash, holds up nearly to the original strength in the pulp, until toward the end of the washing period, when it drops quickly. If there was serious short-circuiting through cracks or otherwise, the displaced solution would be lower in cyanide at the start, and there would be no definite end-point.

The following tests made on three successive basket-charges at the end of the 60-minute washing period by the Liberty Bell chemist, W. E. Tritch, confirm this and show conclusively that the wash is not inefficient.

	Samples of displaced solution.			Wash-water in vat.		
	Lb. KCN per ton....	Au in sol. Oz. per ton....	Ag in sol. Oz. per ton....	Lb. KCN per ton....	Oz. Au per ton....	Oz. Ag per ton....
No. 1	0.14	0.002	0.03	0.07	0.0006	0.025
No. 2	0.12	0.0026	0.03	0.07	0.0006	0.025
No. 3	0.14	0.003	0.035	0.07	0.0006	0.025

In addition, cake-samples were taken and carefully washed by decantation with measured amounts of water, and the cyanide strength calculated for the moisture in the cake. An average of five samplings gave 0.067 lb. more cyanide per ton of solution in the cake than in the wash-water, the greatest difference being 0.12 lb. per ton.

Mr. Bosqui says: "The maintenance of the slime cake in the best condition for the displacement by water is a delicate operation requiring careful manipulation." This applies to the Butters and not to the Moore process, and for this reason: The assumed detrimental condition is the formation of cracks in the cake. Their avoidance is the objective. Now it has been my experience with the Moore plant that cracking is chiefly a function of air-drying, that air-drying varies with the time the cake is exposed to the air while under vacuum, and with the amount of that vacuum. I surmise that this has been Mr. Bosqui's experience, as well, for he says, that during the transfer of pulp, wash-water, etc., "the vacuum is reduced just enough to hold the cake, in loose adherence, to the canvas, yet not enough to dry and crack the cake."

In the Moore plant at the Liberty Bell this "careful manipulation" is not necessary. It is only four minutes from submergence to submergence of the filters, and the cake cannot dry out enough in that time to crack, and, furthermore, does not crack, and the transfer can be made with full vacuum. No particular care is needed. During the corresponding operation with the Butters process, the cake is exposed under vacuum to the air for 30 or 40 minutes, and "careful manipulation" *is* necessary, from what Mr. Bosqui says, to keep it from cracking.

Mr. Bosqui's list of wrongs suffered by the Moore filter during transfer are without appreciable quantitative effect where the transfer is made under vacuum. Where the transfer is made regularly without vacuum, as was tried for a time at the Liberty Bell, and abandoned, the tendencies he outlines are serious, and the results are not good.

From the nature of the case, a greater variation in design is possible with the Moore process than with the Butters process. Consequently, the evolutionary period for the Moore process will be longer before experience indicates which is the best design for a given set of conditions. For the same reason, the early Butters plants were nearer their highest possibilities than were the early

[1] MINING AND SCIENTIFIC PRESS, February 2, 1907, Page 148.
[2] MINING AND SCIENTIFIC PRESS, December 15, 1906, Page 714.

Moore plants, and the Moore process has greater remaining possibilities.

From the various contributions so far made to this discussion, the following I think may be derived: The operating labor is the same for both systems. The power requirements are less for the Moore process. The technical effeciences are about equal. The first cost of a Moore installation is less, and consequently the amortization and insurance charges are less. The royalty charges should be the same. Undoubtedly the Butters process has so far made the best showing for filter-repair expense. It seems probable, however, that the new Liberty Bell filters will compare favorably with the Butters filters.

In conclusion, I think Mr. Bosqui's dictum that the sum of advantages lies with the Butters-Cassel process is based on insufficient grounds, and is incorrect. For small plants, there is probably little to choose between the processes. For plants of medium size with a treatment capacity of, say, 100 to 200 tons per day, where a good side-hill site is available, thereby rendering possible a gravity discharge for the Butters filter-boxes, the operating expenses of the two processes should be abont the same, with the first cost in favor of the Moore plant. Where large tonnages are to be treated, however, or where a side-hill site cannot be had, the inherent advantages of the Moore process, namely its lower power requirements, its greater compactness, its lower first cost, and the higher time efficiency of its filtering units, become of increasing importance, and outweigh, I think, whatever difference in repairs there may be in favor of the stationary filter. In the light of the experience so far obtained with the Moore process, I think there is no question but that rational design, taking account of all possible contingencies whose quantitative effects have been proved important, will eliminate, practically, the faults that have so far developed.

I have just read Mr. Pettis' contribution to this discussion in the MINING AND SCIENTIFIC PRESS of March 23, and I think that his conclusion in the final paragraph is covered by the foregoing. It is worth remembering that the credit for the vacuum-filtration processes really belongs to George Moore. The Butters-Cassel process is merely an inversion technically and historically of Moore's original process, and the greater honor, therefore, belongs to Moore. Had he realized and patented the essential feature, namely, the removal of the filtered cake from the remaining unfiltered pulp by means of its adherence to the filter cloth, as Mr. Brown has pointed out, there would have been no chance for this controversy of the relative merits of the Moore and Butters-Cassel processes.

EDWARD H. NUTTER.

Telluride, Colorado, March 30.

IN THE RE-BUILDING of San Francisco, methods of economical leveling and construction have been sought out and practised to the maximum degree. As an instance typical of this, we may cite the work done on the Crocker building, standing at the corner of Post and Market streets, where every avenue to waste, both material and labor, has been most successfully closed through the exercise of a little ingenuity and forethought, aided by the best of modern crushing machinery. This structure, which is ten stories in height, with a frontage of about 200 ft., escaped any serious damage from the earthquake, but was gutted by fire. The frame of the building being intact, nothing more was necessary than a reconstruction of its interior, and the contractors at once hit upon the profitable plan of utilizing for concrete mixture all bricks, tiling, stone-work, and flooring, that had to be removed. Suitable apparatus was therefore installed, and, as fast as the work of tearing down made this material available, it went directly to a Gates breaker fed from bins supplied by chutes from various parts of the building. After being crushed to the desired fineness, the product of the breaker passed to a mixer, and as the concrete material issued from the latter, it was taken by a system of elevators and conveyors to all parts of the building where needed.

The Ferry Building, San Francisco.

The San Francisco of Today.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

San Francisco lives, with a throbbing life that pulsates through every artery of her multifarious commerce; the sorrowful yesterday and the hopeful tomorrow serve but to enclose a vivid present. It is only a year since a catastrophe, unexpected as a collision with a vagrant comet, devastated her marts and consumed her stores, yet today she presents an aspect that appeals less to the sentimentalist wanting to bemoan a doleful fate than to the man of action keen to appreciate a recovery magnificent in its vigor. Certainly to those whose privilege it is to take part in the rebuilding of a great city and to be an insignificant portion of her renewed vitality, the spectacle of the rehabilitation of San Francisco is immensely stimulating. To those who knew San Francisco in former hours of silken ease, to the mining engineer whose nomadic steps brought him frequently within her hospitable walls, to the prospector who was wont to tarry awhile among surroundings so full of contrast to his rigorous calling, to the seaman to whom the Contra Costa hills ever looked a welcome across the Golden Gate, to all of these, if haply they be in other lands, the picture of her reconstruction will touch a reminiscent chord. The story is told elsewhere in this journal by two engineers better qualified than the writer, but for the sake of those that want to know just how San Francisco looks, we give three or four photographs that tell their story more eloquently than words.

Looking Down Market Street.

First comes the Ferry building. This is the gateway familiar to every traveler. Amid the devastation of the earthquake-fire the tower of the Ferry building stood a silent sentinel. Had it fallen, the effect would have been intensely depressing. How nearly it collapsed is known only to those who examined it after the earth tremor had passed. This imposing structure is farthest from solid ground, for it stands on the sea-wall, all the space intervening between it and Montgomery street, a distance of half a mile, being filled ground, won from the margin of the bay. The building stands on piles that were sunk 60 ft. into the mud, without reaching solid rock; the anchorage is on concrete surmounting the piles. The tower itself has no base, it rests on two heavy girders that cross the main exit of the building. Hence the earthquake swung it cruelly. The tie-rods were displaced as much as 16 inches, the rivets were sheared, and the plates broke away, leaving the entire structure in a shaky condition, although it did not fall, and the lower part of the building remained in service during the conflagration and the anxious days that followed. Among those to suffer from the disarrangement were the officials of the State Mining Bureau, whose quarters are on the third floor. The terra cotta tiling, which lined the inside of the tower, fell down, and into the storerooms of the Bureau. The ceilings were made of plaster spread on wire; the cracks ran along the joints of the wire mats and from each crack the plaster descended. Some of the stones of the tower itself dropped through the slate roof over the laboratory and drafting-rooms of the Bureau. A few days afterward a heavy rainstorm flooded the library and injured the hanging maps, although the books themselves were saved by covering the cases with tarpaulin, until the repairs were made, during the past month. In the museum, the vibration displaced the labels of the mineral specimens, so that they had to be freshly identified and re-labeled. Some side cases tumbled, breaking the glass, and in a few instances it happened that they fell over horizontal cases, so that the contents of both became mixed. On the whole, however, the result was mainly inconvenience to the officials, for no serious damage was done to the valuable possessions of the Bureau.

The tower has been re-covered with concrete made from the material obtained by crushing the blocks of sandstone with which it was formerly veneered. The main building was not seriously injured and retains its stonework. The photograph shows the new loop for the trolley

service, in place of the old turn-table. It is to the credit of the Federal Government that the reconstruction of the tower was completed within six months. The clock has a new white dial and its hands once more mark time for the thousands that cross the Bay every morning and evening.

Another photograph gives a view looking down Market street, toward the ferry. Market street is the Broadway of San Francisco, its main avenue, and its greatest thoroughfare. The view is taken from the Flood building, a big structure that survived the earthquake and has been put into service, being occupied mainly by the offices of the railroad companies. In the right foreground is seen the first floor of what is to be the largest reinforced concrete building in existence. It is the Pacific building and is to have nine stories. Since the photograph was taken it has been constructed as far as the third story. The photograph shows a group of men feeding a gyratory crusher, the product of which descends into a concrete mixer in the basement. Along the platform in front are openings to admit the descent of stone that does not need crushing. It may be mentioned that in many cases the stone taken from wrecked buildings is being crushed on the spot for use in concrete applied to new buildings. Thus the granite of the old Stock Exchange is reduced for employment on the new Hopkins building on Pine street. Brick from the ruins is also used in this way, tests having proved that it is safe to do so. Even old concrete is crushed and made part of a fresh mixture. In this way much of the old San Francisco helps to build the new city that is rising from the ruins.

The gore in the left foreground, made by the junction of Ellis and Market streets, is to be occupied by an eight-story concrete building. On the corner opposite, but on the same side of Market street, the Union Trust building will be erected. The tall structure in course of construction almost in the centre of the picture is the Humboldt Savings Bank, which will be a new feature of the City. The site had just been cleared at the time of the conflagration. It testifies to the nerve of the people of San Francisco that after the fire the owners decided to make the building five stories higher, involving an additional expenditure of $150,000. The construction is of reinforced concrete on a steel frame and the engineers are Lindgren & Hicks, the latter being the author of an article on another page of this issue. Lower down the street on the right is seen the exposed side of the Kamm building, occupied by Uhl Brothers, dealers in wall-paper; this was partly destroyed and has been partly renovated. The front of it did not suffer much, but the back of it, where the paper was stored, was injured by the fire.

A little farther down Market street, and the dominating feature of the picture, is the Call or Spreckels building, which, in many respects, represents the most signal triumph of mind over matter, of engineering skill over nature's unrest. For this structure, 320 ft. high, survived the earthquake, though swept by the fire. The top of it must have rocked more than a foot, and probably 18 inches, during the earth tremors of April 18, 1906. From the thirteenth story upward the stone exterior was loosened, so as to require re-setting, but the great steel frame remained intact. In the basement are the vaults of the National Bank of the Pacific, and it is worthy of record that after the fire was spent and the building cooled, the mechanism of the ponderous doors worked perfectly, proving that they had not shifted a hair's breadth. After the partial destruction of the City, this towering structure stood like a lighthouse amid a sea of devastation. Of the Examiner or Hearst* building on the opposite side of Third street, there was nothing left after the earthquake and fire had done their work, although previous to the event it had presented a bold front of stuccoed pretence. This building had self-supporting walls and was not of the modern type; it is to be succeeded by a 22-story structure of improved design.

Below the Call building is the Monadnock, a large office building approaching completion at the time of the disaster. It has become an important hive of activity since then and its modern steel structure was tested by the earthquake with results satisfactory to all concerned. Though not of heavy construction nor of the finest type of steel frame, it did well, especially when it is noted that the west wall was lacking at the time of the earthquake, so that it was an unfinished three-sided box, calculated to feel the vibration severely. That end of the building is now being completed.

Still farther down Market street, too far for the photograph, there comes a sad gap—the site of the Palace hotel. This landmark of San Francisco, built thirty years ago, was gutted by the fire, but its brick walls stood in gaunt desolation until torn down, to make room for a new and more handsome building. The walls were reinforced with iron rods and straps; the building was honeycombed with interior brick partitions, and this vital feature made it particularly well adapted to resist a shock. The Palace hotel was built just after the earthquake of 1868 and the builders had made provision for such an occurrence, never foreseeing that a general conflagration would be the accompaniment of the other danger. Even the large charges of dynamite exploded in the futile effort to stay the advance of the conflagration, failed to bring down this building, although they injured others in the vicinity. The inefficient use of dynamite was a feature of the San Francisco fire that is particularly regrettable, for it was successful mining that was responsible for the early growth of the City. The authorities used the explosives like farmers, at a time when the advice of numerous mining men was readily available.

Coming back, up the street, on the left is the white front of the Mutual Savings Bank building, at the corner of Kearney and Market streets. Just beyond rises the dark mass of the new Chronicle building, a modern steel structure that passed through the trial without serious injury from the earthquake, while the adjoining old Chronicle building was shaken and badly injured by the fire. Moreover, the presses and other heavy machinery on the top story fell through and shattered the successive floors underneath. The framework rising from the street, and indistinctly observable in the photograph, is the scaffolding in use for tearing down the old Chronicle building, which was erected twenty years ago, and was the first of the skyscrapers in San Francisco.

For the sake of old times we publish a photograph of that part of the City where Montgomery street meets Market and Post streets. To the left are the Grand and Palace hotels, with the Call building in the distance; in the middle comes the gore of the Crocker building, like the prow of a great ship; to the right is the Hobart, adjoining the Union Trust, building; and just above it is the Masonic Temple. At least they *were* there; the present tense is not permissible in every case. But even this pathetic reminder need not depress a citizen of San Francisco, for on the site shown in this photograph there will be a group of buildings more superb even than those of the past. On the site of the Grand hotel there is to be erected the 14-story building — of steel, stone, and terra cotta — of the Metropolitan Banking Co. The new Palace hotel will have 10 stories, probably faced with brick and terra cotta. The Call and Crocker buildings have already been renovated, and will look just as they

*The three leading newspapers of San Francisco are the *Call* owned by J. D. Spreckels, the *Chronicle* of M. H. de Young, and the *Examiner* of W. R. Hearst.

used to. The Union Trust building is being handsomely repaired. On the site of the former Masonic Temple there will be a splendid 12-story building, probably the finest banking establishment in California. It will be occupied by the First National Bank; the first three stories will be faced with granite, the next eight with pressed brick, and the top story with terra cotta. West of the Crocker building, between it and the Chronicle, will be a 10-story office building, running back to the site of the former Mechanics Library. It is obvious, therefore, that the financial centre of San Francisco is destined shortly to present a superb appearance.

Finally, in the last photograph we have a bit of the ruins, not in their unkempt disheartening ugliness, but with a touch of poetry. This Greek portico, with its Ionic columns and Doric freize, was the doorway of the house of Mr. A. N. Towne, on California street. It looks like a bit of Palmyra or Corinth; the blasted palm is eloquent of disaster and the marble columns give mute evidence of the flames that overwhelmed a beautiful home. To the left are the gaunt spectres of several tall buildings and past the columns there looms the City Hall.

This portico served as a subject for an impressionist picture by Charles Rollo Peters, who represented the scene under the mantle of night. He called it 'The Portals of the Past.' And if you go there, on the top of California hill, you can see now, through the portals of the future, a greater city rising from the ruins of the old San Francisco. The merry sound of the riveters, the clang of hammers, the confident voices of engineers, can be heard. A score of giant steel buildings stand in conquering strength amid the ruins of the wooden structures that the fire destroyed; already the site of these is being occupied by brick buildings of various sizes, and the ground is being prepared for the architect. To the west is the portion of San Francisco that escaped the fire, it makes a big town in itself, and it shows but few marks of the earthquake. To the northward is the magnificent form of the Fairmont hotel, a noble white building in the style of the Italian renaissance, which was nearly finished at the time of the fire, and was not seriously injured by the earthquake. It is to be opened with proper ceremony on the anniversary of the disaster. Beyond are Telegraph and Russian hills, whose sides were practically swept clean by the conflagration, but they are now thickly dotted with dwellings. The old ghastly sky line, with its grim evenness of contour is broken by habitations, and the scene is one of cheerful restoration. Turning to the right, there stretches the heart of the City, where its offices, stores, and banking houses stood in confident security on the night of April 17, to become a seething furnace twenty-four hours later. You would not believe it now, for the skyscrapers remain, most of them rehabilitated and renovated, thousands of new buildings have sprung up, the street cars are moving, the pavements are crowded with hurrying people, the walls of buildings in course of construction are dotted with workmen, the wooden frames of reinforced concrete rise everywhere, the thump of the pile driver is heard, and the whistle of the steam engine. All is life and activity. On the water-front is the tower of the Ferry building, and beyond it lies the blue expanse of the Bay, dotted with green islands, furrowed by the white ferryboats; farther still rise the Contra Costa hills, in peaceful beauty, dreaming in a purple haze, athrob with soft enchantment. The touch of sadness has gone, it is a vivid life that throbs all around, it is unresting energy that vibrates in the air, we look through the portals of the future and feel glad again as "in the days when the world was young and life an epic."

The Portals of the Past.

A Year of Reconstruction.

Written for the MINING AND SCIENTIFIC PRESS
By CHARLES DERLETH, JR.

In the following description, it is my purpose to give a short review of the extent of structural damage within the earthquake and fire belt of April, 1906, followed by a general outline of the amount of rehabilitation accomplished during the past twelve months.

There is no need to tell the story of disaster. Enough has been said on that score; still, many of my readers no doubt are quite unfamiliar, after all, with the magnitude of destruction, especially in San Francisco, so that some reference at least to the extent of fire and earthquake losses is necessary in order that one may better appreciate the enormous amount of rebuilding and repairing that has been accomplished already.

It is my intention to devote my remarks particularly to San Francisco, because of the enormous losses in that city due to the subsequent fire. Many persons have purposely over-emphasized the destructive effects of the conflagration, both in San Francisco and Santa Rosa, with the mistaken notion that any argument that appeared to divert attention from the earthquake would be beneficial to the home community. I have never sympathized with that attitude of mind, which would tend to belittle the earthquake as a primary cause. The property and business interests of San Francisco and its vicinity have nothing to lose by frankly admitting that there was an earthquake in California, that it meted out considerable damage, and that it was the prime reason for the great fire.

It is possible that in the future our community may be again startled by earth vibrations; but this possibility should not detract from the importance of San Francisco as a thriving and growing centre of trade. I am perfectly convinced that a straightforward exposition of the destruction of April, 1906, is to be encouraged on every side, in order that there may be a more general and thorough understanding of our local engineering and architectural problems, especially since it can most decidedly be shown that first-class constructions of the various types, from modest wooden buildings to modern fire-proof steel-framed sky-scrapers are thoroughly able to withstand an earth tremor of the severity of the *temblor* that visited California a year ago. With honest and scientific construction, there never could have been, except at places on the line of the fault itself, such a complete collapse and disintegration of structures as to promote a general conflagration. With high-grade building, even with the cutting off of the water supply of a great city, fires could not start in many places at the same time, and the menace of a conflagration might be avoided. In San Francisco, within half an hour after the earthquake, fires were reported in nearly sixty different places, and always among cheap buildings of wood or brick construction. It was not in the first-class buildings that fires started.

The important destruction to engineering works was found in a belt about 50 miles wide and nearly 400 miles long, extending along the Pacific Coast with the Bay of San Francisco at its centre.

Within this belt the most severe racking of structures occurred right on the fault-line, the most striking examples being the Pilarcitos conduit, the San Andreas dam of the Spring Valley Water Co., and the Pajaro bridge on the Southern Pacific railroad, about 1,500 ft. south of Chittenden station, where the railroad crosses the Pajaro river. These structures, all well designed, were much damaged, or even ruined, as in the case of the Pilarcitos conduit, because of the large and unequal movements of the ground along the rift.

The intensity of shock within the earthquake belt varied greatly. Well built structures that rested on hard and rocky surfaces were little damaged. Rock formations and structures resting upon them were shaken by an elastic vibration without differential movements of the surface materials, and in such instances wherever the construction was intelligent and honest, it withstood the shock. There are many examples of successful resistance on the hard ground summits in San Francisco. Comparatively little damage was done in cities like Santa Cruz, San Rafael, and Berkeley, which rest on a rock foundation, or other sound coherent material.

Within the belt of great destruction are found many spots where decided differential surface movements occurred, though at a distance east or west of the fault-line. Examination shows localities to be overlaid with loose incoherent material. In one place, we find a loose river deposit; in another, a marsh; in a third, an artificial fill. Examples of destruction in such localities are found (1) near Salinas, where the Spreckels sugar mill, a first-class steel cage constructed building, was much racked; (2) in the San Bruno marsh, near South San Francisco, where the Crystal Spring conduit of the Spring Valley Water Co. was smashed; (3) on the filled areas of San Francisco in the Mission district, and along the water front, near the Ferry building, where the street surfaces were deformed into waves, and structures with weak and faulty foundations were so generally destroyed.

In all these cases the differential motions were of a secondary nature, and not directly connected with the movements along the fault-line. The general vibration of the earth's crust caused marshes that were near the centre of disturbance to shake like bowls of jelly; and alluvial deposits and artificially filled lands were much shaken and shifted upon the firmer ground beneath them.

Within the belt of great disturbance there was a line of less intensity of shock approximately parallel to the fault and traversing the bottom lands of the valleys that contain Santa Rosa and Healdsburg in the north, and Agnews and San Jose in the south, with the bay of San Francisco as a central feature. These bottom lands are alluvial deposits of soft incoherent material; structures resting upon them were severely shaken, though in general there was little, if any, differential movement of the ground in such cities as Santa Rosa and San Jose. Structures situated near the foothills of these same valleys and resting on firmer ground were observed to suffer very much less.

It should be remembered that within the earthquake belt there was much destruction in Santa Rosa, San Jose, in the Salinas valley, at the Agnews Insane Asylum, Stanford University, Redwood City, Inverness, and the region of Tomales bay, in general along the fault, and in particular in the city of San Francisco. In these localities, except where there were unequal movements of the ground, or where structures were extremely near the line of rift, and therefore were subjected to violent vibrations, the unusual amount of earthquake shattering can and must be ascribed to faulty, ill-advised, or dishonest construction.

To an eye-witness visiting these places immediately after the catastrophe, the impression was depressing indeed. One could hardly believe that so much racking, shattering, and collapse could ever be repaired within a reasonable amount of time. One certainly got such an idea by visiting San Jose, Palo Alto, or Agnews. After all, however, the earthquake destruction was relatively slight, say five or ten per cent of the total damage, when compared to the wreck of fire in San Francisco and Santa Rosa. To the eye-witness of these conflagrations and

their results, it seemed well-nigh impossible that order could be brought out of chaos so soon.

During the past six months I have conversed with many visitors to San Francisco. A common remark made by the stranger is: "Why, I expected to see more building within the limits of the fire area in San Francisco." Such statements are usually made on the spur of the moment and without careful thinking. They never would be made by one conversant with building operations; indeed, they appear almost profane to one who lived in the ruins a year ago, and who has seen day by day what has been accomplished against great odds.

Last week I spent several days in San Jose, and except for a few shattered and unoccupied buildings like the City Hall, the State Normal School, a High School or two, and one or two churches, one would hardly know that the city had been so terribly racked a year ago. The business streets are as active as ever, and the scars of earthquake and small local fires have been almost entirely removed. It is well to notice that the scars still remaining in San Jose mainly represent either municipal construction or buildings of private community enterprise. The same observation may justly be made for other centres of population within the earthquake belt. In every case the worst destructions are observed in public enterprises, which leads me to a criticism which I think can be made in general for cities in the United States; namely, that the poorest buildings are generally public structures. In California, the earthquake brought home vividly at least the partial truth of this remark. It is a sad reflection that cities and communities all over the United States are lax in their building of municipal and public structures. On the other hand, the Federal buildings proved the excellence of the work done by the Government, for they were among the few that survived intact. The people, in erecting city buildings, schoolhouses, or churches, expect far too much for the money appropriated. The result is improper construction, and we need not wonder then that public structures showed themselves to be seriously weak when tested by the earthquake.

Structures of this kind were helpless in withstanding conflagrations, as they were not sufficiently fire-proofed. Herein may be noted one of the great lessons of the earthquake and fire. It seems, however, that the American people, like the rest of humanity, like to forget disagreeable circumstances. The citizens of San Francisco, for instance, appear no longer seriously to consider many of the great improvements that were to be introduced into the reconstructed city. For example, much has been said regarding the necessities of further fire protection, construction of local and distributing reservoirs, the introduction of salt-water systems of pipes in the business district, the widening of streets, the introduction of fire limits within which only Class A buildings might be constructed, provision for fire-boats, and so forth.

A Bit of the Old San Francisco.

In Santa Rosa the fire obliterated the business part of the city. This was caused by the general collapse of brick buildings at that place. The business portion of Santa Rosa burned because fires started simultaneously in the rubbish, and the facilities for fighting a conflagration were too limited. There was never a lack of water, as in the case of San Francisco. Nearly all the brick buildings were thrown to the ground by the *temblor* because they were carelessly constructed, and because the lime-mortar used and bond of brick-work were especially poor. However, if one goes to Santa Rosa today, the main street is again as active as ever; and everywhere within the heart of the town, structures of importance

are being erected, generally of a type far superior to those that existed before the fire.

At Stanford University, a commission consisting of Professors Marx, Wing, and Durand, has been pushing the reconstruction of the Campus buildings and most substantial progress has been made in repairing the older buildings and the arcades that connect them. Similar encouraging statements may be made in regard to repairs and reconstruction in Redwood City, Inverness, and other smaller centres, as well as for individual important structures that stood near the fault; for example, the Pajaro bridge at Chittenden and the Spreckels sugar factory at Salinas.

Of necessity, the great destruction to the Spring Valley Water Co.'s conduits was rushed, and most of the important work done on repairing the main pipe-lines was accomplished within the first month following the fire. Particular reference need not be made at this time to the substantial and stupendous water works reconstruction of those early days, because much has already been written on that topic. Moreover, the report of Mr. Herman Schussler, chief engineer of the Spring Valley Water Co., leaves little to be said. This report appeared some months ago.

In San Francisco, the first necessities demanded the housing of the homeless people and the sheltering of business activities. Of hardly less pressing importance were the traffic problems; the opening of streets and repairing of electric car-lines. Incident to these traffic problems, of course, came the question of removal of rubbish and debris.

The amount of work that has been done in the building of temporary homes, temporary business offices, and warehouses, in the clearing of streets and removal of rubbish from sites for new buildings, in the repair of street-car lines and the rehabilitation of power-houses, water and gas mains, sewers, etc., has been, during the past twelve months, decidedly stupendous. This gigantic work has been done and its effect is visible in the rapidly returning life and regular activities of the City; but to the stranger, the result may not appear commensurate with the effort. These labors, great as they are, do not show new buildings and ornamentation; they do not directly help to adorn the general landscape.

The whole northeastern portion of the city bordering on the Bay, stretching to Black Point and the Presidio on the west, and containing Telegraph and Russian hills, was practically wiped out by the fire. If one stands today on Nob hill in the vicinity of the magnificent Fairmont hotel, one sees in that burned district innumerable houses, frame to be sure, but substantially built, covering almost the entire area. These represent some of the new and necessary homes of San Francisco. Looking south from Nob hill, one can command a view of the Mission district, most of which, too, was entirely swept by flames; and there again, one now sees after a lapse of twelve months, innumerable small frame and brick houses, completed, or in course of construction, for the use of stores and dwellings; and interspersed with these smaller houses, many larger ones of brick or concrete for factory and warehouse purposes.

The great fire consumed nearly every house in the region of the city bordering the east side of Van Ness avenue. The passage of ten months saw that avenue of rich dwellings turned into a busy retail district for shoppers. The buildings in this vicinity are mainly of wood. They were hastily constructed for store purposes and must be considered temporary. Nevertheless, temporary as they may be, these buildings represent a large outlay of capital and an enormous expenditure of labor. From Van Ness avenue, eastward, upon ground that was swept clear of houses, building after building has been erected; the first ones were wood and cheaply constructed, but those lately begun are substantial, brick walled, mainly of Class C type, for stores, dwellings, apartments, or business. In short, the whole burned district is covered with wood and brick buildings; many are of temporary character, but in total they represent a most wonderful exhibition for twelve months of labor.

While most of the streets are cleaned of debris, many of them are still in a deplorable condition, because of the necessity of repair to sewers and water-pipes, to gas-mains, etc. The work which has been done in these respects is stupendous. To the visitor seeing the City for the first time since the great destruction, it is the sight in the streets of open trenches for sewer and water-pipe repairs, and the deep holes on adjoining building sites representing foundation operations, that give an idea of disorder and slow improvement, especially in the lower Market street district. But to one who appreciates the situation these are indications of great advancement. The rubbish has been cleared away, a great number of buildings, temporary and permanent, have been built, traffic has resumed, and business is on a more active basis than ever before. The bank clearings of San Francisco are greater than they were a year ago.

While it is true that the streets are still torn up in places, notably on lower Market street, and while it is to be observed that in the business district many of the most important and valuable building sites are mere excavations, it should be remembered that innumerable substantial foundations for new structures have been sunk, and that the vital things of city life have been replaced during the past twelve months. All is in readiness now for detailed, visible, and permanent construction.

From the preceding remarks, a distant reader might imagine that as yet there were no new or rehabilitated buildings of first-class construction in use in the heart of the City. Let me remark that about 20 Class A buildings passed through the conflagration, and a number of them have been tenanted for several months. The Kohl, Monadnock, and Atlas buildings, with some inconvenience at first, housed tenants within three months after the fire.

To give a good picture of what has been done in the heart of the City, and what may be expected within the next six months, it might not be amiss to speak in particular, on the one hand, of some of the important structures that passed through the fire and have already been repaired, and on the other, of buildings that were begun after the fire and are now nearing completion.

The fire completely destroyed all Class C buildings, and those Class B structures of brick-work and stone, whose interior floors and walls were of wood, or partially of wood.

Notable instances of the more substantial buildings belonging to the B Class, which were destroyed, are the Emporium and the Palace hotel. The Palace hotel has been completely torn down; the Emporium is being dismantled, and probably a part of it will be retained in the reconstruction. It is well to note that, of all the building types, the fire ruins of the best examples of Class B construction offer the greatest hindrance to the reconstruction of the City. A conflagration usually destroys them completely so far as possible repair is concerned, but leaves the remains sufficiently intact to make it necessary to expend large sums of money, and to consume much time, in razing them.

Structures with self-supporting outer walls and independent interior frames of rolled steel with fire-proof floors and partitions are not desirable. The best of them

cost as much as first-class steel-frame curtain-walled buildings. In the event of a conflagration, however, they are dreadfully damaged and leave costly ruins. The Sloane building, the Academy of Sciences, the old Chronicle building, the Mills building, the Spring Valley building, and the Wells-Fargo building support this argument. Most of these structures, together with a few others, are now being repaired, at great cost and consumption of time. The difficulties presented by their reconstruction are apparent when we consider how little has been done in either razing or repairing such buildings, especially in comparison to the repair of the few Class A structures that passed through the same conflagration.

By Class A is meant buildings with steel frames, supporting all wall and floor loads, with all parts fireproofed. A list of such structures existing in San Francisco at the time of the fire with details of construction

The Kohl, the Merchants Exchange, and the Mills Buildings.

is given in the accompanying table, taken from the earthquake report made by the local association to the American Society of Civil Engineers. Although gutted by the flames and greatly damaged, they nevertheless presented to the fire a decided resistance in comparison to the dangerous hulks left of buildings that had self-supporting walls. From these statements it must not be supposed that the Class A structures in San Francisco went through the fire comparatively unharmed. Their frames, structurally, were mainly left in safe condition; but buildings as a whole were greatly damaged. Studies of the Baltimore and San Francisco conflagrations show that first-class fire-proof buildings exposed to a conflagration may be expected to sustain heavy damage on all items of construction except foundations and steel frame. These two items represent approximately 20% of the value, and to this may be added about 10% for other salvage, chiefly masonry work; thus giving 70% damage. On account of the high prices for labor and materials in San Francisco during the past year, the cost of repairs to Class A buildings has, in some cases, been equal to the original cost of the structure.

These statements may seem unreasonable, and it may appear paradoxical to state that a first-class fire-proof building may, by conflagration, be damaged to an extent of at least 70% of its original value. Nevertheless, buildings of this type must be encouraged, as they retard and possibly limit conflagrations when properly grouped, especially if window and other exterior openings are protected. In San Francisco the Class A buildings were especially lacking in exterior protection. In a building like the Call the elevator-shafts acted like chimneys under forced draught. Intelligently equipped Class A buildings, properly grouped, and protected at exterior and interior openings and shafts, in combination with efficient city fire departments and a more general use of local water-supplies with automatic sprinkler-systems for individual important buildings, will decidedly help to retard the spread of a general fire.

There are many other reasons why Class A buildings should be encouraged, because even when gutted by flames, and with 70% of the first cost destroyed, they are, comparatively speaking, readily rehabilitated, thus permitting a quicker resumption of business and a great saving of rents. In San Francisco, this observation has brought home keenly the value of first-class buildings, as against the Class B, even of the best type. The Monadnock has been occupied for at least six months, the magnificent Flood building appears today almost without a blemish; yet across the street, the ruins of the Emporium look almost as bad as they did the day the fire stopped. The Mills building, the Sloane, the Academy of Sciences, the old Chronicle building, are still mere hulks, and it will be many months before these repaired structures will be ready for occupancy.

All this time rents are being lost and business is retarded. On the other hand, structures like the Fairmont hotel, the Call building, the St. Francis hotel, the

Marston building, the Merchants Exchange, the Mutual Savings Bank, the new Chronicle building, the Telephone building, the Shreve, the Kohl, the Bullock & Jones, the Atlas, and a few others are already alive with life and business.

In repairing some of these structures, many extremely interesting problems of repair and reconstruction have been presented. One of the most fascinating of them has been the shoring up of walls or floors of enormous weight in order to take out and replace steel columns that buckled from heat, due to faulty fire-proofing, or to the collapse of fire-proofing from especially great and prolonged heat. One might dwell on the topics of reconstruction of San Francisco Class A buildings at considerable length, but such a discussion is beyond the purpose of this article. Of about twenty Class A structures all are now rapidly reaching complete re-establishment, and they are furnishing for the new San Francisco a nucleus of life in the heart of the old City.

CLASS A BUILDINGS IN SAN FRANCISCO.

After the fire, for several months, business was diverted to Fillmore street, and then to temporary quarters on Van Ness avenue. It was believed by some that the centre of business activity would permanently remain near Van Ness avenue, but there is now every indication that the City's life will return completely to the old stands.

Among the repaired structures in the heart of the business district, one finds deep excavations. These excavations are seen on every hand, and in combination with scarred streets, give to the passing eye a notion of disorder. Careful observation, however, will show that these excavations contain pretentious foundations, already completed, and ready for large superstructures. Foundations, in building, commonly consume time, due to difficulties naturally presented. Since many large ones for new buildings of Class A construction have been completed during the past six months, it is safe to predict that the next half-year will bring to view a much more substantial evidence of reconstruction. Before July, steel skeletons will be rising on every hand.

One of the most notable of the new structures in San Francisco is the Humboldt Savings Bank. Its foundations were laid after the fire, and today, its steel frame is completed, with a large part of the reinforced concrete walls and floors already enveloping the frame. The building occupies a lot on the south side of Market street, about 100 ft. east of Fourth street. On Market street the front rises 17 stories, with two additional stories in the dome. The rear portion of the building is 13 stories high. In plan the structure measures 50 by 170 ft. This building represents, in my judgment, one of the soundest forms of first-class construction, in that it typifies a building with a unified steel frame, to which frame are substantially anchored curtain-walls, floors, and partitions of material of integrity like reinforced concrete, capable of remaining intact under severe vibration.

Another building worthy of special mention is the Whittell building. The foundations of this structure were in place in February, 1906, and the steel frame was completed a few days before the earthquake. The Whittell is situated on the north line of Geary street, about 80 ft. east of Stockton street. The structure rises to a height of 17 stories. The curtain-walls are of brick, and the floors of reinforced concrete. The structure contains many ingenious and substantial features, notably in the foundation and spandrel girders, which make it capable of withstanding earth vibration.

Having been started earlier than the Humboldt Savings Bank it is much nearer completion, the curtain-walls being in place nearly to the top of the structure.

Many other steel-frame buildings of similar proportions are rapidly developing, and will be substantially completed within the next twelve months. The new Palace hotel and the wing to the St. Francis hotel are well known examples.

The most striking feature, however, of San Francisco's reconstruction is the advent of reinforced concrete. This type of construction is being introduced to an extreme degree, so that one might almost dub it a fad in San Francisco. There were practically no reinforced concrete structures in the City before the fire; certainly there was no true reinforced concrete building, because of the successful objection and opposition of some of the building trades, which strenuously and consistently opposed the introduction of reinforced concrete as a substitute for brick-work.

The little reinforced concrete construction in existence prior to the fire was mainly found in floors and interior columns. It is well known that floors and interior columns, irrespective of the particular materials of which they were built, suffered very little through earthquake vibration. Such parts of building-frames in general were not subjected to severe earthquake stress or destruction. Consequently, nothing definite can be stated regarding the earthquake resistance of this type of construction.

There were a number of reinforced concrete buildings within the Bay region of San Francisco that were not subjected to subsequent fire; and all evidence in these cases, though extremely restricted, is decidedly favorable to this type of construction as being able to withstand earthquake motion for structures of limited height. This evidence, together with the natural integrity and coherence exhibited by reinforced concrete, has brought it prominently to the attention of builders, and today one may see structures of this class being erected on every

hand. In fact, one might refer to the reconstruction of San Francisco as an era of reinforced concrete.

There is no question in my mind but that reinforced concrete with proper design, materials, and workmanship, will produce a most excellent building. On the other hand, it should be equally observed that no type of construction lends itself more readily to the abuses of the quack and the self-advertised expert. One may find in San Francisco today buildings of reinforced concrete of many types in process of construction; the different examples involving every conceivable patented device, or employing every possible principle of design. Some of these schemes are good, others are decidedly bad. Of the systems of design, some are based on sound principles of mechanics and embody intelligent treatment of details; others are quack constructions pure and simple.

During the past six months, reinforced concrete structures have collapsed in different parts of the country, notably at Long Beach, California, and at Rochester, New York. It would not be surprising to note in the near future the collapse of some reinforced concrete structures in San Francisco. With no other type of construction can a good design be made of no avail more easily than with reinforced concrete, where poor materials are used, with careless or pernicious workmanship.

Because of these disadvantages, however, one should not decry the use of reinforced concrete. It should be encouraged to the greatest extent, but should be carefully supervised, both in the design office and in the field. Reinforced concrete is suitable for many purposes, and has many possibilities of most desirable application, and it certainly has its place in an earthquake country. It would be very unfortunate if quack design and careless construction should injure its reputation in San Francisco. However, I do not advocate the use of it for skyscrapers, but would prefer for the highest buildings a structural steel skeleton; this skeleton might be clothed in reinforced concrete or in masonry work properly reinforced, and anchored to the steel frame.

Immediately after the fire, the building ordinance was revised, as well it might be. The old ordinance, while it was spoken of as a building law, was really composed of 17 different and sometimes conflicting enactments of the Board of Supervisors, made at different times during the last ten years. Of course it was full of conflicting conditions, and was also open to the criticism that it was indefinite and of poor arrangement. While the present building law may be readily criticized, it is a vast improvement upon the old ordinance. It naturally cannot be perfect; no such instrument ever could be. It has many defects and contains a number of clauses that should be changed as soon as possible. Anyone remembering the circumstances and pressure, however, under which the new ordinance was arranged, will have considerable respect for the authors of the law, for it is based on sound practice and good scientific judgment.

For political or business reasons, some clauses were introduced into the ordinance that were not advocated by the engineering advisors; such, for instance, is the clause limiting the height of Class A buildings to one and one-half times the width of the street. Class A buildings have proved themselves perfectly safe against earth vibrations and the best kind of retardents to the spread of conflagrations. There is no reason for limiting their height. The origin of this clause came from a desire to force property owners to widen some of the important but narrow business streets, such as Montgomery. The height-limit clause having failed to produce the desired effect, it has just been repealed.

One of the most unfortunate conditions affecting building in San Francisco is the lack of sufficient inspection on the part of the building department. A building law can never be a specification. It should be as terse and to the point as possible without treating details, and have for its object the protection of the City and general public against persons who want to build too poorly. The building ordinance should provide penalties if it is broken. While an ordinance partakes of the nature of a specification, it should only do so as far as it is necessary to elucidate some of its provisions. As a law, the ordinance tells what shall be done; and in order that its provisions may be enforced, it, in some cases, tells how the work shall be done. It is the function of a specification to tell how to do a thing. The sole and vital reason for the existence of an ordinance, however, is merely to tell what to do. What is needed in San Francisco is not a revised ordinance with greater detail of specification, but rather the present ordinance with a few modifications, and, if possible, greater brevity, coupled with an efficient building department commanding the services of properly trained inspectors.

HIGH CLASS BRICK WORK.—The difficulty that the wreckers are having in razing the Palace hotel in San Francisco does not bear out the reports which are so freely circulated concerning inferior construction in that city. Most people who have traveled know the Palace hotel. It was seven stories high, 300 by 225 ft., and was built in 1870. The bricks were laid in a mortar composed of lime and cement, with strips of Norway iron and steel cables at frequent intervals. The mortar is too hard to be scattered by the cleaning machines. The supports include 100 pillars weighing seven tons each. The walls are first dynamited and then pulled down by hoisting engines — 1½-in. steel cables — equivalent to the strength of 10,000 men. Notwithstanding this, the strips of wall remain unbroken on the ground and require picks and sledges to loosen the bricks. The laborers working below the surface are frequently compelled to desist because of fire which is uncovered. In many places the combination of wood, plaster, and mortar has formed a sort of charcoal, which, secluded from air by piles of debris, has been smoldering ever since the fire on April 18. Boiling water or steam is often found in these places. The crowds of laborers are constantly on the alert to avoid being burned or scalded. There are 10,000,000 brick in the building, and the debris will fill 80,000 wagons. The contractor is receiving $30,000 for wrecking the building, and the value of the salvage is estimated at $20,000.—*Construction News.*

PROGRESS ON THE PENNSYLVANIA TUNNELS.—Work on the Pennsylvania Railroad's New York terminal and tunnels is going forward with great rapidity. A large portion of the tunneling is actually completed. There has been another meeting of tunnels—this time in Long Island City. The southern-most of the four tubes being driven from East avenue under the Long Island Railroad passenger terminal toward the East river has reached the river shaft and is now connected with the tubes that go out under the water. Recently the headings bound in opposite directions under Thirty-second street, Manhattan, came together nearly under Third avenue, so that there are continuous passages from the East river to Fifth avenue under both Thirty-second and Thirty-third streets. Under the East river the cast-iron tubes, bound in both directions, have gone about 500 yd. Those going east from Manhattan, having started a full year earlier, are more advanced. The three to the south, known as *B*, *C*, and *D*, are now piercing the rock of Blackwell's Island reef. The tubes bound from the Long Island City side toward Manhattan are about 350 ft. out under the water.

A Question of Mining Law.

A correspondent submits the following case:

A and *B* have a law-suit over a claim in 1905. Neither of them do any work in that year (1905). *B* wins the suit, but does not do his annual work in 1906, claiming that the land office excused him from doing his annual work in 1905. Consequently the claim would not be open for location until January 1, 1907. But *C* makes a location on December 25, 1906, and *B* locates the property on January 1, 1907, in other parties' names. Was the claim open for location in 1906, and does *C* have the 60 days to record and do a ten-foot hole, even though it takes some time in 1907? Who would be the valid locator?

Our reply is as follows:

As between *A* and *B*, neither might have been permitted to take advantage of the other's failure to perform the work during the pendency of the litigation. As against *C*, the excuse of non-performance by *B* during the year 1905, would be available only upon showing that he had been prevented from doing the work by force, or violence, actual or threatened. The question implies that at some point of time in 1905 the litigation was finally terminated in *B*'s favor and that thereafter and prior to January 1, 1906, he had the opportunity of doing work, or at least he might have resumed work on January 1, 1906, and saved the location from liability to forfeiture. As he did not do so, the ground became subject to re-location on that date and was so subject on December 25, 1906, when *C* entered and initiated his right. *C* would be allowed the same time to complete his location as if he were an original locator. The fact that this period of 60 days extended into 1907 is of no moment. It is possible that *B* might have resumed work on January 1, 1907, and thus prevented the re-location of *C* becoming effectual, if on that date *C* had not completed his location by complying with the State law. As to this the decisions are not harmonious. But as *B* did not resume work, but sought to re-locate through others within the 60 days allowed *C* to complete his location, *B*'s rights must yield to *C*, whose re-location would become effectual upon completion of the statutory work and recording his certificate. Timely resumption of work may intercept and cut off rights initiated but not perfected, but an adverse re-location made before the expiration of the 60-day period cannot have this effect.

THE NORTH STAR MINE.—During the year ending December 31, 1906, the North Star mine, at Grass Valley, in Nevada county, California, produced a total value of $826,326, at a cost for current operation of $392,445, and an operating profit of $433,881, from which additional costs were paid for general Mine Development, amounting to $122,822, thus leaving an available mining profit, over both operating and development costs, of $311,059. Outlays during the year for Improvements, $27,561; Property Purchase, $2,171, and Sundries (Accident Fund), $1,424, mostly chargeable to Capital account, amount to $31,157, resulting in a cash remainder of $279,901. Out of this sum there were paid dividends amounting to $250,000, 10% on the issued capital stock, leaving a net surplus of $29,901 still available for dividend account. The above stated total value was wholly produced from the North Star mine during 1906, and was obtained from 84,672 tons of ore, milled with an average yield of $9.75 per ton, at an average operating cost of $4.63, with resulting profit of $5.12 per ton, less additional outlays of $1.45 per ton for development work. The above stated costs of operation and development amount altogether to $6.08 and leave a realized profit of $3.674 per ton. Outlays during the year for Improvements, Property Purchase, and Sundries amount, per ton, to $0.368, leaving a net cash surplus of $3.306 per ton (about one-third of the realized value of the ore), available for dividends.

Making the Best of the Ruins.

DURING the conflagration of a year ago, the quarters of Chas. C. Moore & Co., engineers at First and Mission streets, were burned, leaving only the foundations and the upright cast-iron columns of the outer walls, which were badly cracked by heat, but were repaired so as to form the nucleus of the present building. This, it will be noticed, consists of a two-story frame structure, with the original brick walls repaired. The ground was covered with melted iron, lead, zinc, and copper remaining from the destruction of the large stock of machinery on hand. This mass of metal had to be blasted before the site could be cleared. This building was completed and occupied by September 6, 1906. Contracts secured by this firm since the fire include a complete electric plant for the Pacific Light & Power Co., a total of 15,000 kw.; city of Pasadena, complete electric plant; Fairmont Hotel, and Johnson Bdg., electric lighting engines; complete 60-stamp mill and cyanide plant for the Tonopah Development M. Co., and other mining companies.

Reinforced Concrete Construction.

Written for the MINING AND SCIENTIFIC PRESS by LEWIS A. HICKS.

The use of reinforced concrete for buildings in San Francisco has been wisely limited by the building ordinance to eight-story structures. Where greater height is desired resort must be had to a steel frame of cage construction, which may be clothed with six-inch curtain-walls of reinforced concrete and stiffened by the usual fire-proofing and slab-floor construction of the same material now recognized to be the best available method of building floors for steel buildings.

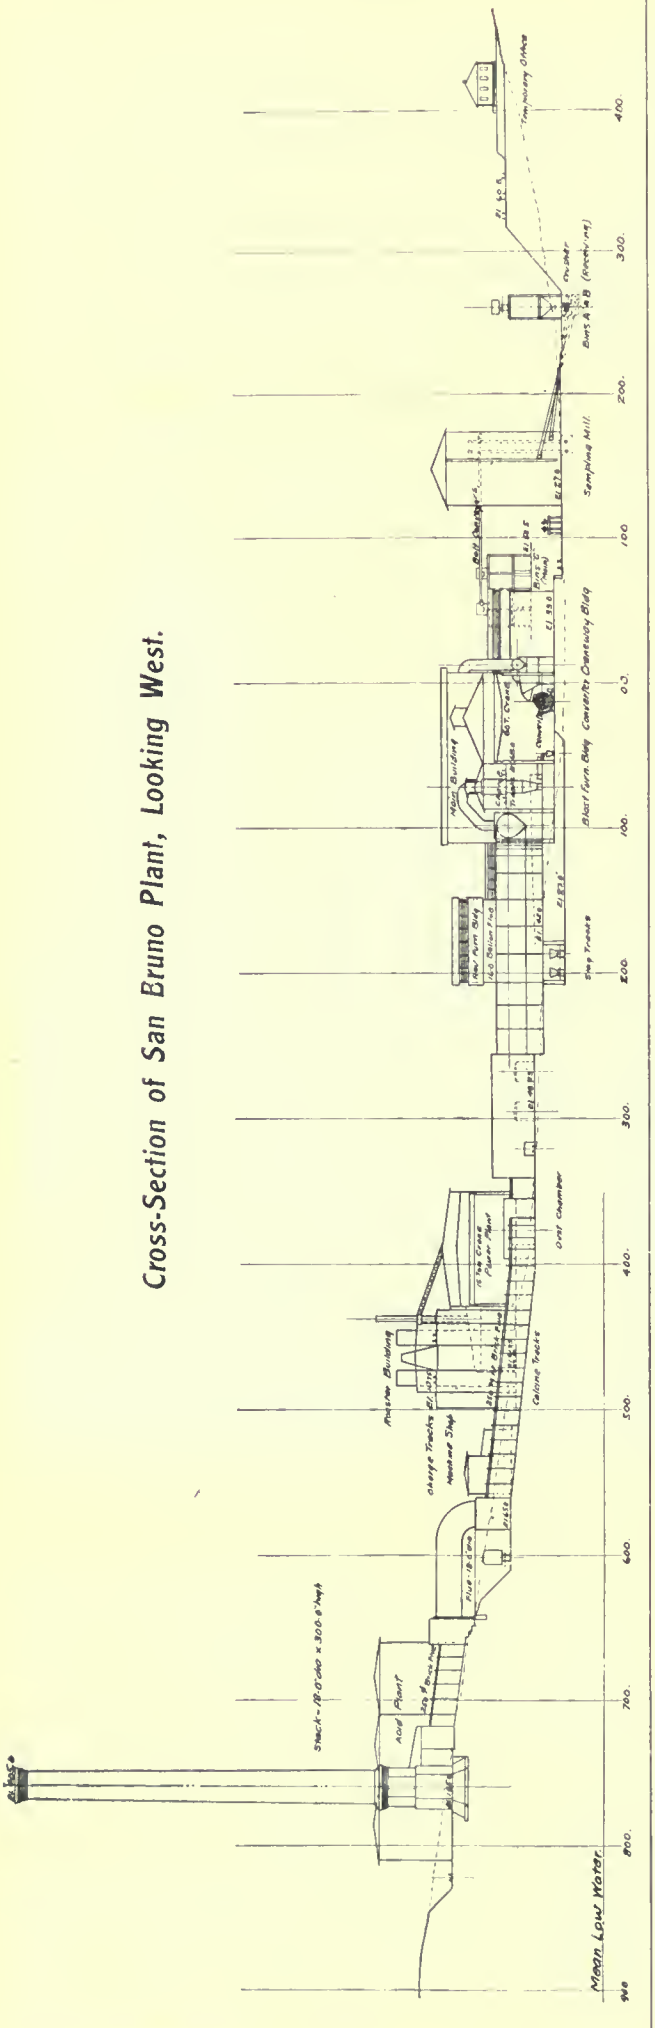
Before the earthquake, the efforts of those interested in introducing this comparatively new material had been abortive owing to the active resistance of persons interested in the manufacture of clay products, the opposition of the bricklayers unions, and the general inertia of the building trades to accept changes in long established methods of construction. When the pressure of this conservatism was removed by the conditions following the fire, there was a prompt reaction in the public mind in favor of the indiscriminate use of a material that would furnish greater security against damage by earthquake and fire than the brick construction formerly prevailing, and without entailing the excessive cost of a steel frame. For a time it seemed as if every building put up was to be made of concrete, but a sufficient interval has now elapsed to make it possible to outline broadly the place in building work that it is well adapted to take, as well as such economic limitations as insure the use of other materials for certain purposes.

It is probable that everyone who has witnessed the destruction done by earthquake and fire to some extent shared the feeling that the new San Francisco must be built of enduring materials such as would forever prevent the recurrence of such a disaster, but it is now apparent that in the struggle to maintain down-town property values the character of the improvements must be largely determined by the ability of the owners to pay for them.

The ground floor of any building used for business property produces revenue disproportionately large to that earned by other floors. Where ground-values are high and owners do not have the funds in hand to make improvements bearing an economic relation to the value of the site, it often happens that the rentals from a low two or three-story building of the cheapest type will return a reasonable interest on the cost of such improvements, and maintain intact a high ground-value until such time as appreciation justifies an extremely high building. Where this solution of an owner's problem is adopted, it is apparent that the cheapest construction, satisfying the requirements of the City ordinances and the reasonable demands of the lessees, should be used. It will be found that this is best and most quickly secured by the use of brick walls with interior wood construction for posts, girders, joists, and partition walls.

When money is available, and the locality affords commercial use for high buildings, approximating in cost the value of the land on which they stand, all considerations seem to combine to suggest a steel frame. Ordinance limitations, tested security, certainty of the continuity of rentals, and permanence of the investment appeal to the owner who has money available to take

Corner of Market and Kearney Streets.



Cross-Section of San Bruno Plant, Looking West.

advantage of extremely high buildings, which can yield revenue from additional stories disproportionate to the rest of the structure, because owing to the fixed land value the total cost does not increase proportionately with the earning power.

Between these two extremes there are a large number of people owning valuable street-frontage with deep lots who must soon find some commercial use for their property and who desire fairly permanent improvements of moderate height but of Class A character. It is among such that reinforced concrete will find its most extended use.

An eight-story office-building having large ground-area properly situated to secure tenancy can be operated more profitably than a narrow tall building with the same floor-space. The property on the south side of Market street between First and Seventh streets, although held at high frontage-values, has such great depth that it is peculiarly adapted to permit the profitable combination of the necessary factors of availability, large ground-area and relatively low buildings of moderate cost and permanent character.

These requisite conditions are most successfully fulfilled by a building with reinforced concrete frame-floors, roof, and curtain-walls, with its front veneered with stone, brick, or terra cotta bonded into concrete backing and all its structural members fire-proofed with a secondary skin of metal furring and plaster furnishing protected air-space. Such a building is Class A in every detail of construction and in appearence, and in its virtual power to resist fire and earthquake it is, in my opinion, within the limit of height considered, equally as reliable as a steel-frame structure.

The amount of concrete used in fire-proofing the columns, beams, floor, and roof of a modern steel building is practically sufficient to build the same members in reinforced concrete, and the difference in cost of the two structures will be roughly the difference in the weight of steel used. The elimination of two-thirds to three-quarters of the steel required for a steel frame is entirely practicable, but the saving is not as significant as would appear at first glance. The cost of a finished Class A structure will range from four to six times the cost of the steel frame and the saving effected will therefore amount to from 10 to 15% of the cost of the improvements.

Where the relation between the value of the ground and the cost of the building is normal, or as one to one, there follows that the saving on the entire investment amounts to from five to seven per cent. It will frequently happen that an owner will prefer to pay this additional cost for the sake of having a type of construction that has been tested to a finality. It is also true that in incompetent hands this apparent saving of five per cent may easily shrink to disappearance, and that time, apparently in favor of the concrete type, may be wasted to such an extent that the steel frame will gain rather than lose by such a comparison.

On the other hand natural advantages favor the concrete frame. The steel required can be secured from local stock and the other materials are of local origin. There has been heretofore very little shop-work in concrete construction analogous to fabrication work in steel manufacture, but we are now having the columns and beam-forms for an eight-story concrete building manufactured in a planing mill from shop details similar in every respect to that provided in steel shops. The forms are lettered and numbered and delivered to the job where they will be erected from a setting plan with a derrick having a boom long enough to pick the material up from the street and set it in any part of the structure. With proper apparatus and methods it is evident that the com-

pletion of a concrete frame should not require more time than the erection and fire-proofing of a steel frame.

We erected the last four stories of the Corder building at Thirteenth and Franklin streets, at Oakland, in five weeks, including the wall enclosure; this is a record that can hardly be bettered. Under these circumstances the time required to fabricate and ship a steel frame from the East, involving a minimum of two to four months, can be saved, but as a portion of this period must be used in back, to the writer's detail, into which the concrete backing clinches, holding each brick separately. The brick is laid to a line in the usual manner; it is then breasted with timber and backed up, and the resulting construction is integrally a whole and practically monolithic. The projections of the terra cotta sections are also filled solid with concrete.

In addition to the field of usefulness pointed out there is a wide opportunity for reinforced concrete to displace

The Bay of San Francisco.

Showing position of new copper smelter in relation to neighboring towns.

either case to prepare foundations, the saving in time will not be important.

I do not believe it possible to secure satisfactory architectural exteriors in cement, but I consider that the backing up of finish clay-products with a reinforced concrete curtain-wall is the only method yet devised successfully to protect the facing material from earthquake distortion. The building occupied by the Breuner Furniture Co. in Oakland is faced with pressed brick and terra cotta backed with six inches of concrete. The brick were manufactured with a dovetail slot at the slow-burning mill-construction in factory and loft buildings where heavy floor-loads make it especially desirable. No material ever introduced has so quickly made its way into general use and its useful application is apparently to find examples in every branch of construction.

ON THIS PAGE we give a map showing the exact position of the copper smelter being built by the Selby Smelting & Lead Co. On the page opposite will be found a cross-section of the works.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE production of gold in Nova Scotia in 1906 was 14,000 oz., or about 1,000 oz. less than in 1905.

CONSULATE REPORTS state that 233,598 tons of freight left Mexico for the United States in 1906, going by the all-rail routes.

THE slope of the vanner is generally from three to five inches in 12 ft. When a corrugated belt is used the inclination is greater than with a smooth belt.

A MINING COMPANY incorporated under the laws of Arizona, and having its certificates marked "not subject to assessment," can not levy an assessment legally.

THE Calumet & Hecla lode consists of a bed of conglomerate 12 to 25 ft. wide, in which the copper occurs as native metal, the average yield being about 2½ per cent. The hanging wall is a fine-grained diabase.

MUNTZ metal amalgamating plates are used in the Thames district of New Zealand. They absorb but little amalgam, and can be cleaned of amalgam without the use of steel scrapers, and are therefore advantageous in custom mills.

FOR amalgamating plates, only the purest and softest annealed Lake Superior or electrolytic copper should be used. Annealing is necessary to soften the hard skin formed by rolling and to make the copper porous for receiving the mercury.

THE number of vibrations recommended for Frue vanners is 180 to 200 per minute. For end-shake vanners, the number ranges from 200 to 240. The amount of vibration is generally one inch in all the standard side-shake vanners.

ESTUARINE CLAYS are laid down in shallow arms of the sea. They often show sandy laminations, and are not infrequently associated with shore marshes, due to the gradual filling up of the estuary, and the growth of plants on the mud flats thus formed.

THE steam-stamps used in the Lake Superior region crush from 700 to 750 tons per day. A single stamp, of the compound type, has been known to crush 779 tons in one day. The consumption of water is enormous, from 3,000,000 to 3,500,000 gal. per head per 24 hours.

IN running vanners it is necessary to consider the size and uniformity of size of the feed, the vibrations, rate of travel, slope, quantity of water, and the depth of the pulp bed. There should be no jarring or knocking, no loose joints, and no movement in the foundation, if the best results are to be obtained.

WHEN rocks are subjected to simple pressure and the dynamic movement is chiefly between molecules, the process is called 'static metamorphism;' but where they are subjected to movement and deformation, the process is 'dynamic metamorphism.' There are many gradations between the two, and neither one acts entirely alone.

THE slope of amalgamating plates is a very important adjustment in gold milling. If they are set at too steep an angle, the pulp rushes over them too rapidly and the gold and amalgam have less opportunity to settle and adhere, and the amalgamated surface will be scoured off. If they are not steep enough, sulphides will stick to the plates and reduce their working area. The plates should be perfectly level transversely.

AN excellent flooring, proof against damp and insects, is made by melting in an iron pot 100 parts of asphalt, and one of tar; sand or stone-breaker screening may be added in the proportion of one to four. The surface to be asphalted must be dry, and may be covered with stone chips or screening. It is divided by thin straight edges, set level and well greased. A floor one inch thick requires 12½ lb. of asphalt per square foot.

NOT many mines have been found by geologists, but one of them is the Champion copper mine in Michigan. The rich lode traversing this property was discovered by Dr. L. L. Hubbard, formerly State Geologist of Michigan. He identified the lode as an extension of the Kearsarge amygdaloid bed, and determined its position by geological evidence. Since then the Champion has become one of the richest mines in the Lake Superior copper region.

THE advantage of mounting a machine-drill on a cross-bar instead of on a vertical post, is that, in driving, the machine can be set up and started running while the muckers are taking care of the rock shot down with the last round of holes. If a post were used, it would be necessary to muck out at the foot of the post, clear down to the floor, before the machine could be securely placed in position. When drilling on a bar, the back and breast holes are put in first, and by the time the machine has to be swung under the bar for the lifters, the rock underfoot has all been removed.

THE patent survey of a placer claim is much the same as that of a lode claim, except that it is not limited to such a great extent. The claim must lie within the location boundaries, its lines can not lap over other claims, all known lodes must be excluded, and the deputy must submit under oath to the Surveyor-General's office a description of the soil, vegetation, etc., on the ground included within the placer claim. Two disinterested persons are necessary to make a corroborative affidavit. When placer ground is patented by legal subdivision, no survey is necessary, but a descriptive report must be made.

THE cradle or rocker that was used to a great extent in some placer districts, is a box about 40 in. long and 20 in. wide, mounted on transverse rockers, and having the front end open and the back end closed. The sides slope up from the front toward the back to a height of 12 to 20 in. A screen box 20 in. square and 6 in. deep, having a perforated screen with half-inch holes, is set on top at the back end. Beneath this is a backward-sloping baffle board, or an apron made of canvas or blanket. On the bottom of the cradle are two riffle cleats, about three-quarters of an inch high, one near the middle, and one near the lower end.

A VANNER does its work of concentration on the surface of an endless belt, which is slightly inclined from the horizontal, and receives a rapid shake in the plane of the belt, while at the same time it has a continuous, slow motion up the slope. This agitation, under a film of water, makes the bed so loose that minerals of high specific gravity can settle to the belt, where they have a tendency to stick to the surface, while those of lower specific gravity rise to the upper layer. The travel of the belt carries the heavy mineral over the upper end, where it is washed off, and the surface water washes the light material over the lower end.

Requirements of Modern Mining.

Written for the MINING AND SCIENTIFIC PRESS
By J. R. FINLAY.

The trade journals have entered up the business records of 1906, and the showing in all directions is remarkable. Everybody knows something of the wonderful growth of the mining industry, but few perhaps realize what it amounts to. Without having statistics at hand, I remember that the figures compiled by the U. S. Geological Survey, show that in 1880 the total mineral output of the United States was valued at $370,000,000, and that in 1905 it was $1,677,000,000, an increase of $1,300,000,000 in 25 years; an annual increase averaging $52,000,000. These stupendous amounts, and this swift increase, not only attract the imagination, but they also lead to the practical conclusion that the product of mines is being absorbed by civilization with startling rapidity, so that the question to be asked is not where the market is coming from, but where the supply is coming from. The world's consumption of coal, for instance, is over a billion tons per year, sufficient to make a pile for market five miles square and 60 ft. high; and this enormous consumption is rapidly increasing. This demand has nearly all grown up in two generations. What will be the result in two generations more? Long before the problem shall be reached of securing the last vestige of the world's coal, commerce will have to face the fact that the vast increase of fuel demands cannot be met. If fuel is to become scarce and costly, as recent experience in the Western States shows is liable to happen only too easily even now, what about the problem of producing a greatly increased amount of iron and other metals from less and less favorable ores that will require more and more fuel for smelting?

But neglecting questions that must become vital with our immediate descendants, it is interesting to consider the vast extent and variety of the mining industry as it stands today. The field is so great that it permits only of specialists. Does any one man know, in a practical way, the mode of occurrence of most of the valuable minerals? Does he know coal, iron, copper, gold, silver, lead, zinc, cement, precious stones, as they occur in the earth? If he does, can he possibly know the processes required to get them to the surface, and put them in marketable form? If he knows this, can he possibly know how to market them? If he knows all these things, will he then know how to finance and launch enterprises to exploit them?

We call a man a mining engineer if he can make an underground survey; a mining man if he owns some stock in a prospect. From these crude beginnings the experience of many individuals makes great advances, but it seems incredible that any intellect, or any energy, would be sufficient to get more than a thin comprehension of the vast subject.

I used to think I would be quite a mining man when I reached the position of superintendent of a property. Later I found that achievement to mean little. Success in handling one mine may be due to some quality that may be next to useless in the next one. At the first mine a man may need only operating talent—capacity to organize and get work out of men. At another, such ability may be absolutely unavailing, unless it be joined with intelligence and training in finding ore. As a man's experience in mining widens, he is constantly reproaching himself for want of knowledge on essential portions of the business, until he finally consoles himself with the reflection that if he had learned the things he doesn't know, he might on that account remain ignorant of the things he does know. At best, one's brain and one's opportunity have their limitations, and it does not take an intelligent man many years to convince himself that pretension to know the whole mining business can be nothing but a fraud, and the expectation to do so only a delusion. Nevertheless, if one may cover the requirements in the case of one or two metals, his equipment will be abundant to secure him his 'shoes and tobacco;' and it may be of interest to discuss what these requirements are. I venture the following generalization:

The business of mining involves

1. Ore and mineral deposits.
2. Operation of mines.
3. Processes to render mineral products marketable.
4. Marketing.
5. Financing and organization of enterprises.

The first division is entirely in the realm of natural phenomena and facts. The second and third deal partly with nature in the materials to be handled, and partly with man in the handling of them. The fourth and fifth divisions are wholly matters of human dealings. It is rather painful to the striving engineer, after laboring over the science and technology of his profession, to find that after all he has been working on a small part of his business, and that the least important. In its broad aspects mining is far more of a question of human relations and facts, than of natural relations and facts.

Now it may be objected that this generalization is either self-evident or meaningless. I shall give an illustration to show how all these considerations must be weighed in the commonest problems of mine operation. At Joplin, Missouri, the ore consists of pieces of singularly pure galena and blende, distributed unevenly through the rock. If these ores could be sorted by hand, it would be easy to pick out stuff running from 30 to 60, or 70% in zinc or lead. Naturally it would be desirable to do this, instead of crushing the beautiful crystals in a mill, and thereby losing 20 to 50% of them. Why not do it? Simply because the market conditions at Joplin do not allow it. Local practice, too strongly intrenched for the small operator to interfere with, and doubtless founded upon good reason, dictates that a zinc ore must be cleaned until it carries about 60% zinc. Failure to bring the ore up to this grade is penalized so severely as to wipe out any possible profits in saving mill costs and losses by hand-sorting. It is obviously impossible to depend on hand-sorting to produce from a low-grade mixture an ore that will conform to a rigid standard of value.

Here we see the human condition of marketing reacting imperiously on the method of mining. It makes a mill necessary, where under a different market it might often not be necessary. It throws the industry into a certain channel, out of which the operator cannot go without meeting certain failure. This consideration influences the view one must take of the value of a deposit, the method of mining, the requirements of milling, and, consequent on all these, the financing of a project.

In the Rocky Mountain region the smelter imposes no conditions except a freight and treatment charge, varying within modest limits according to the grade and composition of the ore. Here the question of what it is wise to spend on mining and sorting on the one hand, and how much to lose in a mill and how much to pay for freight and treatment, on the other, is a very broad one. It may be capable of many solutions, each of which may mean a different result in dollars and cents.

A gentleman in charge of a large and valuable group of silver-lead mines announced the other day, with breathless triumph, "I have raised my mining costs 10%, raised the grade of my ore 25%, and increased my profits 100%, and, do you know, my directors are kicking about my high costs!" I submit that in this case millions of dol-

lars in mine valuation depend upon a trick of mine operating. What a different view one would take of the property before and after the determination of the above results!

In like manner we hear of important interests in coal mining being rendered dangerous as investments, because the railroads will not furnish cars. Here the question is apt to be, not what kind of a mine have you, but, what are your relations with the railroad?

It is probably true that in the majority of cases the determination of trade and finance questions is left to specialists in those lines. Indeed, in any event, there must be questions of this kind that are as inherently the work of specialists as the work of an assayer or a machine-runner. My point is, that the mine manager or the mine valuer must be broad enough to recognize the fact that the man who sells ore, or buys ore, or promotes a scheme of mining enterprise, has just as much claim for recognition as a factor in the business as the mine superintendent or the metallurgical engineer. Perhaps far more. Reflect, that the men who now control the greatest enterprises are not mining engineers; they did not even begin as mine owners; they were business men whose business was refining oil and selling it, or financing smelting enterprises; they were men whose wits were sharpened by competition. There is no competition in the ownership of a bonanza mine. The owners are generally spoiled by having too much of a snap; they have not, as a rule, expanded to the true requirements of their business, and while hugging themselves for their successes, they are really stagnating in a small corner of the field.

Much has been written about mine valuation, and mostly with a failure to recognize the full scope of the subject. Everyone knows that to take samples and measure the ore in reserve by some fixed rule, requires no more than honesty, care, and some knowledge of solid geometry. That does not go far. The mine remains, and new ore is found after the ore once in reserve is gone. The geologist may go further and arrive at a correct conception of the persistence and extent of the mineralization, but does he know what the ore can be mined for? In many cases he does not know. The foundation is laid, let us say, that a million tons of ore may be relied on, carrying a certain amount of various metals. Still the valuation is only begun. The great problems remain of how it can be mined, how milled, how smelted, and how marketed at the maximum profit; and how may an enterprise be organized and financed so as to realize the maximum profit for the investor. I contend that the answering of these questions is by far the greater part of mine valuation. A mine may be a grand success, financed at $10,000,000, and a dreadful failure if financed at $5,000,000. Who will decide this? A man who can operate a mine? One who understands ore deposits? One who can operate a smelter? A man who can sell steel rails or cuff buttons? A man who can furnish the money? None of these. All of them together can perhaps; but very much better a man who can weigh with discrimination the evidence of each.

I venture to say that the men in this country who are able to bring to bear on a gold mine, or a copper mine, or a lead mine, such an equipment, and who have an opportunity to do it, may certainly be counted on the fingers of one hand. If these problems are so complex and far-reaching today, they are sure to be more complex and more far-reaching. What financing and what methods will be required twenty-five years hence, when the world will require several times the amount of mineral products it requires today! It is difficult to imagine, from present knowledge, how such vast demands are to be met. 'Ore in sight' will not meet them. Scientific exploration and development, improved methods, the use of new materials to substitute those now in use, will all help. To do these things is a splendid field for good brains. It is a comfort to know that the business of mining is no fake, but a most essential—and perhaps the most distinctive—part of modern civilization. Many a young man now behind a tramcar, or a drilling machine, thinks mining a pretty tough business. So it is. So is war also a tough business. If war has produced the greatest reputations, mining has produced the greatest fortunes of the world; and in both there is room for future Napoleons.

Ore Deposits Formed at Shallow Depth.

In the Cordilleran regions, as well as elsewhere in the world, veins containing gold with much silver, and, more subordinately, lead, zinc, and copper, are found in flows of volcanic origin. In many cases the geological conditions enable us to say with considerable certainty that these deposits have been formed at a relatively slight depth below the surface, say, from a few hundred to 5,000 ft. below the actual surface of the ground, at the time of mineral deposition. Among these are, for instance, most of the veins of western Nevada, the San Juan region of Colorado, Cripple Creek, and a great many ore deposits of Mexico. These deposits are closely related to the sericitic and calcitic veins formed at greater depths. An unbroken line of transition between them may in fact be found, but at the same time veins formed at slight depth possess certain characteristics of their own.

Gold and silver prevail, though compared to the deep-seated veins with quartz gangue there is more silver, and the native gold is, as a rule, present in a more finely divided form. Pyrite, galena, zinc-blende, chalcopyrite, arsenopyrite argentite, and stibnite are the prevailing ore-minerals, but more complex sulphides, sulphantimonites and sulpharsenites, such as ruby silver, stephanite, polybasite, are more abundant than in deep-seated veins.

In part their presence may be due to a secondary enrichment by descending solutions, but opinions do not as yet agree regarding all of these occurrences. Of gangue-minerals quartz prevails, but it is here often accompanied by chalcedony, opal or other forms of silica. Calcite and dolomite are moderately abundant in the vein-filling, while siderite occurs more rarely. Barite and fluorite predominate locally. Magnetite and specularite, as well as the whole line of the silicates belonging to the greater depths of formation, are absent. Apatite is of rare occurrence. On the whole, as may be expected near the surface, the filling of open cavities is a process of much importance.

The metasomatic processes differ, in character of course, in different country rocks. In igneous rocks of medium acidity a strong sericitization is apt to take place immediately adjoining the vein with attendant concentration of potassium and leaching of lime, iron, and magnesia. Pyritization is also of common occurrence. The solutions appear on the whole to have been poorer in carbon dioxide than those of the deep-seated deposits and extensive carbonatization is therefore less common. On the other hand, the solutions have a tendency to spread from the veins through large area of adjoining rocks, probably owing to more extensive fissuring near the surface, and here, robbed of their most active ingredients, they produce the so-called 'propylitization,' which consists in the development of chlorite and epidote, as well as pyrite, from the dark silicates, and in the eventual degeneration of the feldspars into quartz, chlorite and epidote.—Waldemar Lindgren in *Economic Geology*.

Mining Labor in Australia.

Written for the MINING AND SCIENTIFIC PRESS
By W. J. LORING.

Volumes could be written on the labor question, but it is not the intention to dwell more than lightly on the subject here. During my five years' residence in Australia as the representative of a firm employing 5,000 men throughout the Commonwealth, I have had the opportunity of making a study of the labor question. My experience is such that I have no hesitation in pronouncing the Australian workman the superior of any with whom I have hitherto had to deal in other parts of the world, and certain it is that with proper supervision his right to the pre-eminent position is indisputable. Let us proceed to analyze the characteristics responsible for this happy state of affairs.

Physically, the Australian will compare favorably with any people in the world. He is a big clean-limbed individual, above the average height, partly attributable, it is claimed, to the love for sports of all kinds. The laws of the country are such that they permit ample time for sports and outdoor recreations. Australia is a country of perpetual sunshine, with physical features that practically demand an athletic life; it is no wonder, therefore, that its people are of a cheerful temperament, and brimful of life and energy. The Government adds to the country's natural charms by the reservation and equipment of innumerable pleasure grounds, thus fostering and encouraging the innate love of sport and outdoor life. Of greater importance still is the Australian's advantage from an educational standpoint. An uneducated person is a *rara avis*, and the country's laws providing for the schooling of their younger population are very stringent. Statistics conclusively prove the Australian's scholastic abilities to be miles ahead of those of any other country. While he is an independent fellow, incapable of being driven, and deeply resentful of anything approaching overbearance, the Australian workingman is one who, with fair and square treatment, can be most easily led and governed.

Primarily, it must be explained that the eight-hour shift is in vogue, and in practice, works admirably. It has been thoroughly demonstrated that the worker, under such conditions shows relatively far superior results to those prevailing under the 10-hour and longer shifts. Many years' experience with American labor working 8, 10, and 12 hours per day has served to make me a strong supporter of the eight-hour shift. In this country the eight-hour system is customary in every trade, and predominates in many classes of business. Roughly, in the neighborhood of 50% of the working population are members of labor unions, and it is regrettable to observe of late years a tendency on the part of these unions to agitate for a lesser number of working hours. An argument put forth by one labor leader was that a shift of six hours would show a corresponding increase in the working ranks, and lay the unemployed ghost for ever. To maintain that mining labor is worked too hard is absurd; no man can do himself serious injury in eight hours, no matter how hard he may work. He has the remaining 16 hours during the day to rest, and usually the whole 24 hours on Sundays. Only in some places, in the case of continuous process plants, are men called upon to work on the Sabbath. Eight hours per day is a fair and reasonable length of time to be on duty, and the reduction of the working hours below that limit would be detrimental to both employer and employee.

Long experience has made me an ardent believer in the old adage, "Good pay for good work." The payment of the highest ruling rates will naturally attract the best workers. The West Australian goldfields may be cited as an example, as the labor there was, until recently, of an infinitely superior standard to that of Broken Hill and its environs, solely owing to the fact of the high wages prevailing. A few weeks back the mines at Broken Hill decided on an all-round increase in wages, and I venture to predict that it will be but a short time when the standard of labor at that great mining centre will be raised to a level that will leave little cause for complaint. The effect of this rise in wages will not only alleviate to an appreciable extent the efficiency of the present worker, but it will act as a magnet in attracting good men from those fields abundantly supplied with labor. It is ridiculous to claim that the West Australian is a better man at his work than the man of Eastern Australia can be if the inducements are sufficiently attractive to warrant him putting forth his best efforts. As a matter of fact, the West Australians have practically all migrated from the Eastern States within the past twelve years, and are but representative of the true Australian. Good pay, capable organization, and close supervision have been the fundamental principles responsible for the happy position occupied by labor in Western Australia today. I maintain that it is more economical to the employer, and extremely beneficial to employer, employee, and the country generally, to pay three men 11s. 8d. per day each, than to give five men 7s. per day each. To my own satisfaction, time and again, I have proved in actual practice the wisdom of such a policy. Of course, were it found that no better results could be obtained from the man receiving 11s. 8d. per day than those derived from the 7s. man, my argument would not hold water; but the higher pay spreads encouragement and contentment among the men, and these are two powerful constituents in the promotion of efficiency.

Most certain it is that the men hold the key to the labor question in their own hands — not by way of strikes, but by the demonstration of their worth to their employer. It is often claimed that the employers do not treat their men properly, with the result that the matter is reported to the union, to the secretary, or to a committee appointed to confer with the employers. At this conference the employees invariably air their grievances in forcible terms, and the employer resents the position as an unwarrantable interference with his business. The causation of bad feeling between both parties is oftentimes the result; and the origin of the whole trouble in four cases out of five will be found to be some trifling difference which should have been amicably settled between the aggrieved parties and their superior officer, at the time without recourse to higher councils. The advisability of the men and employers pulling together is so palpable that it is strange to see the difficulties which are allowed to develop without being nipped in the bud. The average Australian workman is a brainy fellow, and it is a subject of wonder that he does not come to recognize this point.

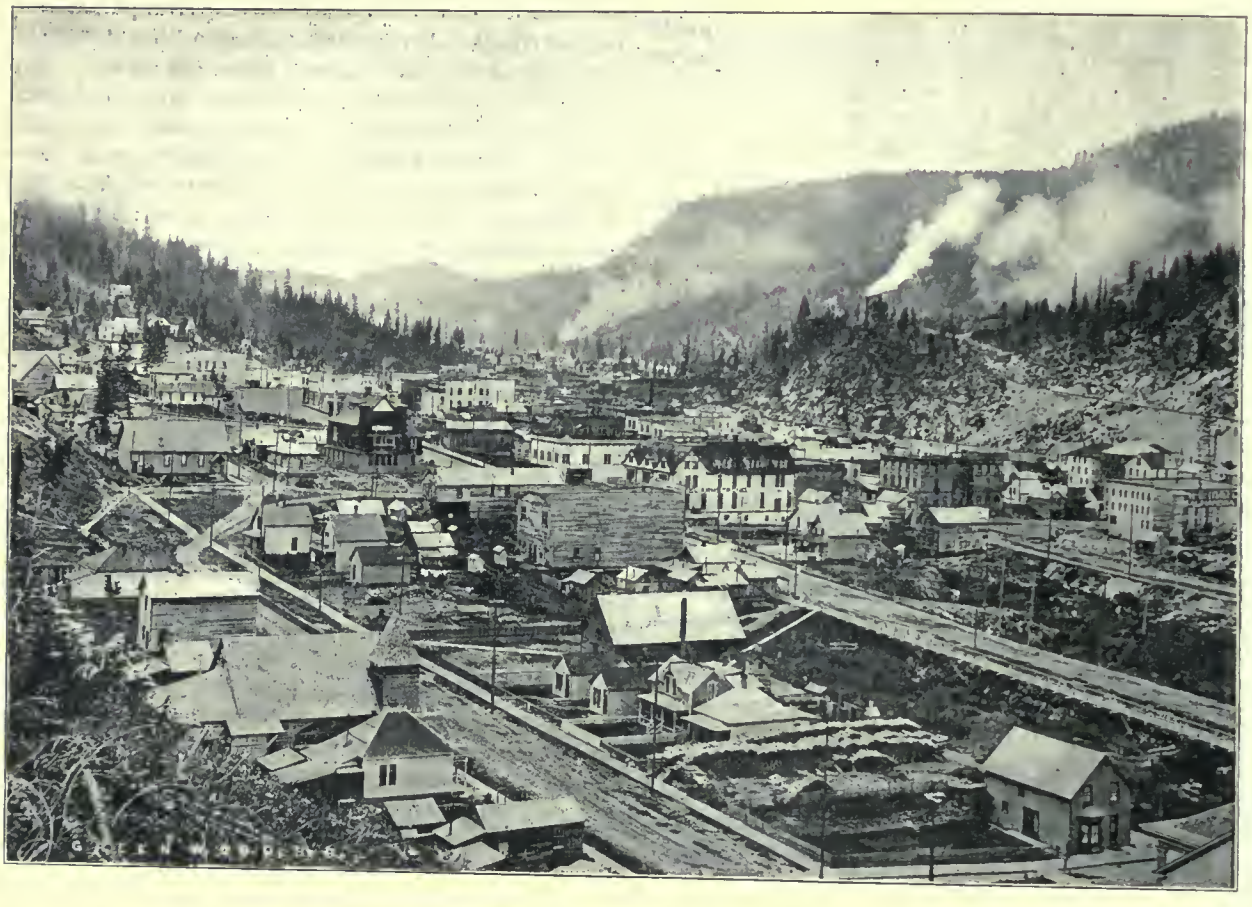
In some instances — particularly in those districts possessing a poor standard of labor — the adoption of the contract system has proved most advantageous. Especially will this apply to underground work. The contract is a boom to the experienced and skillful worker. Through it he is enabled to earn more than the ruling rate by simply exerting his highest endeavors. This method of working also raises the efficiency of the individual and puts him in line for promotion by permitting him to prove his worth to his employers. The effect on the less inefficient worker is also noticeable; he recognizes the goal he can reach by perseverance, and it is an incentive for him to give his employer better results.

Care in the selection of shift-bosses and departmental heads, with a view to the absence of friction, will be found one of the most important characteristics necessary to a perfect working force. Encouragement of initiative and recognition of worth, either by promotion, raise in pay, or reward, are points well worthy of consideration.

Judicious mixing of nationalities has been found advantageous in mines employing a large number of men, but in no instance is it desirable or advisable to allow the percentage of foreigners on the pay-sheet to assume any great proportion. Indeed, great care in this direction is necessary in some quarters to prevent intense friction, and in no country where the English language is spoken should a foreigner be allowed to work underground unless possessed of a working knowledge of English. Many mine accidents in former years can be attributed to this cause, but happily, nowadays, proper attention is given to this factor of safety.

That cheap colored labor is emblematic of low working costs is utterly fallacious. Comparison of the big mines of Australia and America working white labor, with those of the Rand, employing either Kaffir or Chinese, will show footage and tonnage per man in favor of white labor in the ratio of at least four to one. The inference is obvious. The policy of a 'White Australia' is an experiment well worthy of observation. The idea is to exclude all colored races. No person is permitted to land unless able to speak and intelligently write one paragraph of any European language. This language test has solved the Chinese problem, for it is seldom that a Chinaman is able to satisfy the Inspector that his knowledge of English is sufficient to justify his enrollment as a citizen of the Commonwealth. The Japanese, it might be explained, have also to pass this language test to gain admission to the country. One effect of this enactment is the stoppage of the importation of Kanakas to work the sugar plantations of Queensland. Those already here are rapidly being deported to their native lands, and it will be but a short time when the whole of the sugar plantations will be manned by white labor. While this will necessarily increase the cost of production, the Government will undoubtedly offset it by the adjustment of duties on the imported commodity. While it may turn out a bad policy for some parts of the country, the 'White Australia' movement is one with which the whole mining community is deeply sympathetic.

TIMBER CONSUMPTION.— Timber consumption in the United States now amounts to about 400 ft. board measure per capita, while in Europe the average is but 60 ft. The best managed German forest grows on an average about 50 cu. ft. of wood per acre annually. If American forests grew as well, which they do not, they would barely furnish by their annual growth the amount of wood now used. In Europe the amount of timber required for many structures is very much less than it is in the United States, masonry of one form or another generally taking its place. The time will come very soon in this country when the relative cost of masonry and wood will be much different from what it is now, and in consequence the use of timber will be restricted far below the limit of the present time. Methods of preserving timber will be employed far more extensively than today for many purposes where untreated wood is now used. One particularly useful improvement will be the substitution of woods which are now considered inferior for those of high value. An example of this is the gradual substitution in wagon boxes in place of white pine, first of yellow poplar, then cotton-wood, then red gum, and today tupelo.— R. S. Kellogg.



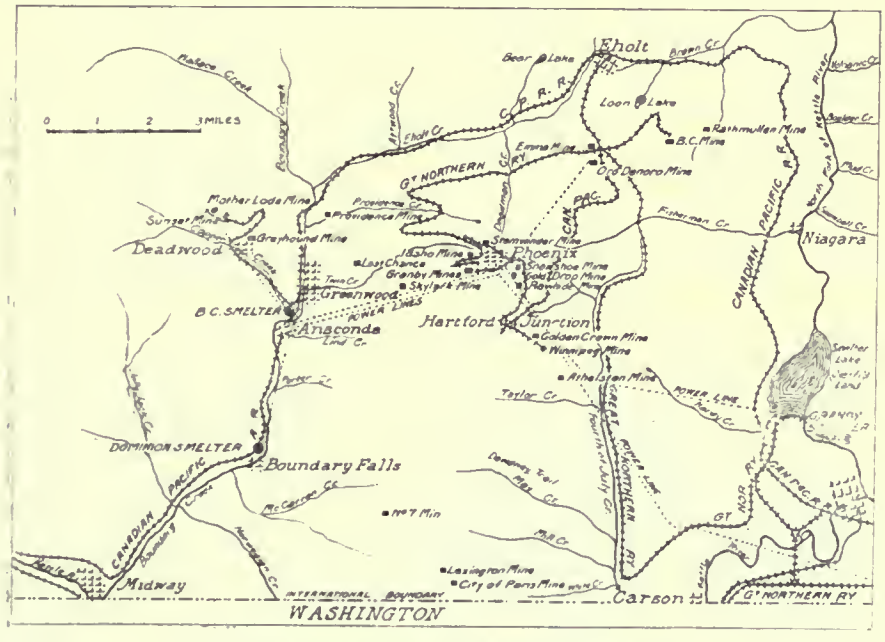
Greenwood, British Columbia.

One of the principal towns of the Boundary district.

The Boundary District, British Columbia.

Written for the MINING AND SCIENTIFIC PRESS
By FORBES RICKARD.

By the Boundary district is meant some 400 square miles of territory in British Columbia just north of the Washington state line and the international boundary; it is a district that is yearly gaining a more prominent place among the great copper-producing areas of the world. An unknown quantity a decade ago, and hindered by the low tenor of its ore, the mining and smelting development of the Boundary has grown to a splendid achievement, made possible by metallurgical advance and the aid of modern mechanical contrivances, backed by faith and a capable management.



The Boundary District of British Columbia.

The combination of geological conditions that has made possible the Boundary district is unique. Its ores are mainly chalcopyrite and pyrrhotite, with the latter mineral predominating. The ore bodies are huge, and the gangue is largely lime carbonate, with the result that the ore is self-fluxing. Railroad facilities are exceptional, and the topography of the country is favorable to cheap mining. Finally, the ore bodies are so large that they can be worked on a maximum scale, with the increasing production and higher copper prices of today. To make such a result possible, in view of the low tenor of the ore mined, the following features are prominent:

1. An ore that fluxes itself.
2. Deposits of large dimensions and fairly uniform contents.
3. Exceptional railroad facilities.
4. The combination of *all* the foregoing conditions to make possible the working of these deposits on a maximum scale.
5. A smelting operation that requires neither preliminary roasting nor a second fusion for the concentration of matte.

While the aggregate tonnage of the district represents mainly the immense output of the Granby, it has been supplemented by the production of the British Columbia Copper Co., from 1901 to 1907, and the Dominion Copper Co., from 1903 to 1907, and these, taken together with the less significant production of a number of small mines in the outlying camps, have contributed no less than 4,500,000 tons, the gross value of which has ranged between $4.90 and $6.04 per ton, and at present copper prices would figure between $7 and $8 per ton for the same metal contents. The production of this district has trebled in the period between 1901 and 1906, beginning with 390,000 tons and growing to 1,160,000 tons.

As an example of the utilization of a low-grade ore to commercial profit, the mining-smelting operation of the Granby company (the leading property of this part of British Columbia) ranks among the most successfully solved problems in the mining world of today. Though

The Granby Smelter, at Grand Forks, British Columbia.

als are mined, the first work was done on the shallow alluvium. So here, in the 'sixties, on Rock creek and Boundary creek, placer mining attracted the early prospectors. It was not until 30 years later that the properties now prominent became actively exploited. In a period of six years, from 1901 to 1906, inclusive, they have produced 135,000,000 lb. copper, having a bullion value of approximately $24,000,000, of which gold and silver combined would constitute one-third of the total. The result in the larger operation has shown a profit of from $2 to $3 per ton; although it is more than that the ore contains $1.25 to $1.50 in gold and silver, besides 27 to 30 lb. copper, nevertheless, it represents, together with the pyrrhotite ore of the Tennessee Copper Co., the lowest-grade deposits that have been made the source of profit by a copper-matting operation.

In the point of tonnage the Granby is at the head of all the metal mines in the Dominion. As cheap handling has been imperative, it has brought into play every possible economy of detail and design, accompanied by an energetic policy of expansion. The head-frame of the new main three-compartment shaft has been recently

finished and everything is being arranged for operations on a continually increasing scale. The proportion between ore reserves and ore consumption is well maintained by means of active mine development in something like 1,000 acres of productive mineral ground. The workings already aggregate 50,000 linear feet, besides diamond-drill bores by which the ore-zones are being tested. In a single year 26,000 ft. of drilling have been accomplished.

The ore is transported 25 miles, from mine to smelter, at a cost of one cent per ton-mile; power is transmitted from the Kettle river and Bonnington falls on the Kootenay river, the longer distance being 80 miles. The installations for long-distance high-tension current transmission give guarantee of ample power for all future demands, at a cost of about one-third that of the steam-plants, which have been superseded in the three principal companies, that is, the Granby, British Columbia, and Dominion. The rates to the two smaller consumers is $33 per h.p. per annum.

The first work in the Boundary district was the development of the Mother Lode claim of the British Columbia Copper Co. at Deadwood, followed by the opening of the Old Ironsides claim of the Granby group at Phœnix. Later there came the development of other camps, notably Summit, where a good deal of work is being done by the British Columbia Copper Co. The enormous surface showing that resulted from the early work, induced the building of the Canadian Pacific Railway from Robson, on the Columbia river, and, later on, the extension of the Great Northern branch line from Marcos, in Washington. Whatever the influence of this competition upon freight rates in general, there has been active competition between these railroads in bidding for shipments from mine to smelter. This applies particularly to the business of the Granby company, as the Deadwood properties of the British Columbia Co., including the Mother Lode, do not yet get service from the Great Northern. The Great Northern Railroad was built on permission granted by the Dominion government. It was not subsidized either by land grant or otherwise.

Granby operations began with two small furnaces, increased to four and then to six furnaces, with a total capacity of 1,800 tons per day. Then came the building of much larger furnaces, whereby the addition of two furnaces more brought the capacity up to 3,000 tons daily. Changes are now being made that will make the capacity of the smelter one-half as much again. Even then the mine will not be overtaxed and the development underground has already anticipated the demands of this increasing smelter capacity.

Ten years ago the Granby was a prospect with not much more than 150 ft. of work done on the Old Ironsides claim, which has been the backbone of the property. The great development since then has been directed to the exploiting of an orebody from 200 to 250 ft. wide and something like 2,000 ft. long, and with a healthy appearance in depth. Other orebodies are being explored in the Gold Drop and Monarch ground of the same company. These mine developments, taken all together, could be brought up to a pitch making them capable of maintaining a production of 5,000 tons daily. The *Boundary Mining Journal*, in reviewing the progress of the past decade, uses a picturesque phraseology when it writes: "In 1896 the silence of the centuries brooded over many places in the Boundary where in 1906 the varied voices of a complex civilization awake the echoes from the fir-clad hills. In ten short years the metamorphosis has been complete; from a little-known territory to one widely known; from the prospector's tent to the modern business buildings; from the primitive pan to the modern smelting furnace "

The geology of the district has been mapped from field-work by R. W. Brock, of the Dominion Geological Survey, in the Report for 1902, under the head of "large low-grade copper-bearing sulphide deposits." There is a singular absence of oxidation in these orebodies, which may be due to the protection afforded by 'drift' that, in the Glacial period, mantled this whole district. Glacial phenomena have been so much in evidence and so widespread in these parts as to warrant the Geological Survey in the platting of glacial striae throughout the region.

The distribution of the ore deposits seems to be along north and south lines, with the main camps of Phoenix, Deadwood, and Summit nearly paralleling each other in broad zones of mineralization. The formation varies from one camp to another and includes limestone, tuff, and chloritic-hornblendic schist, all of them much altered and high in lime, through calcareous replacement. Whether in one rock or the other, there is everywhere a distinct bedding of the country, and besides the same general direction of strike there is a prevailing dip of the vein-system to the eastward.

While the limestone areas in the three camps are scattered and recognizable only in limited patches, much limestone enters into the mass of rock of which the vein-stuff is composed. These orebodies, particularly in the instance of the Mother Lode at Deadwood, are intruded by porphyry dikes and sheets, which have induced a contact-metamorphism with the garnet, epidote, and magnetite characteristic of contact-metamorphic zones. The porphyry of the Mother Lode has been classified by the Canadian Survey as alkali-syenite or pulaskite. Granite occurs here and there and at Summit a wide vein of magnetite flanks a granite boss, which separates the orebodies of the Emma mine from those of the Oro Denoro.

A structural feature that more than anything else determines, in my opinion, the extent and shape of the orebody of the Mother Lode—and it will apply to many other mines of the Boundary—is the tendency of the lode-fissuring to flatten, so as to decrease the angle with the bedding, until the one plane so closely approximates the other that the two systems of fracture merge. Where the orebody already tends to spread away from the fissuring and along the bedding planes the result is a poor definition of the ore, greatly in contrast to the clear-cut lines prevailing where the fissuring holds at a sharp angle to the bedding. It may be assumed that the porphyry masses that have been developed in the workings of the Mother Lode have played an important role in the general mineralization and ore occurrence.

Diamond-drilling has a good field here and has been successfully applied to the finding and prospecting of orebodies throughout the district. It will doubtless continue to be utilized largely in the future. The cost of drilling ranges from $2 per foot for horizontal holes to $2.50 and $2.75 for angling and bottom holes.

In regard to the smelting problem, the Boundary ores meet the factors of iron sulphide proportion, lime, the inclusion of sufficient copper content for the matting process, and the percentage of free silica in the charge, in such a way as to constitute a flux without admixture of foreign rock or custom ore. Though some ores are bought, no dependence is placed upon a supply of custom ore high in copper, as is often the case elsewhere. The charge is ore and the ore is the charge. From 12 to 14% of coke is used. The smelting practice requires no preliminary roast and no bedding of the charge. Direct smelting to matte of converter grade dispenses with matte-concentration by re-smelting—the double smelting, as it were, which has in many cases to be resorted to in order to get matte sufficiently high in copper for con-

verting. Zinc in harmful quantity is a consideration that is here eliminated. Still, with all these favorable features, it is no child's play to contend with the necessary uncertainties of smelter operation and a low-grade ore, the whole establishment being under pressure to drive to the top notch of capacity in keeping clear of the ever-crowding ore supply, which in the one operation of the Granby means something near 3,000 tons daily.

Where rapidity of handling and the maintenance of a large scale of operation are so essential to profitable operation, it is not to be wondered that difficulties have beset smaller plants when attempting to do from the start what their predecessor had only done after years of laborious experiment and systematic upbuilding. And, as the Alaska-Treadwell operations in the early history of that company barely paid with 250 to 300 head of stamps, so in the gold-copper operations in the Boundary, even with a high copper quotation, there has been no real profit until production reached something like 400,000 tons for the single year.

The situation in regard to supply of coke and coal has been very bad recently; a shortage has been due to the September-December (1906) strike of the Fernie mines of the Crow's Nest Pass Coal Co. This shortage has interfered seriously with the regular operations of all the Boundary mines, but it is only now being relieved. With a full fuel supply re-established, the three larger companies operating in the district should get their production and smelter consumption up to 5,000 to 5,500 tons daily, equivalent to 40,000,000 to 45,000,000 lb. copper for the year.

While the details of cost of operation of these three companies are closely guarded in each instance, the following crude tabulation puts together some information that covers the subject in a general way. This relates to the Granby, the costs of which, as compared with the other two companies, have been from 1½ to 2¼c. lower per pound of copper, under the average obtaining during the last few years:

	1905.	1906.
Tons smelted, including some custom ore	590,120	832,346
Copper sold, lb.	14,237,622	19,939,004
Average price, cents per lb.	14.36	17.78
Silver, fine ounces	212.180	316,947
Average price, cents per oz	58.30	64 68
Gold, fine ounces	42,881	50,020

Figuring the 1905 production on a value of:

Copper, 28 3 lb. per ton	$3.92
Silver, 0.015 oz. per ton	0.27
Gold, 0.072	1.44
	$5.63

With a recovery of $4.66, and a working cost of $3.05, the net profit was about $1.60 per ton.

Exterior view of B. C. Smelter.

Slag run on one side of furnaces and converter floor on the other.

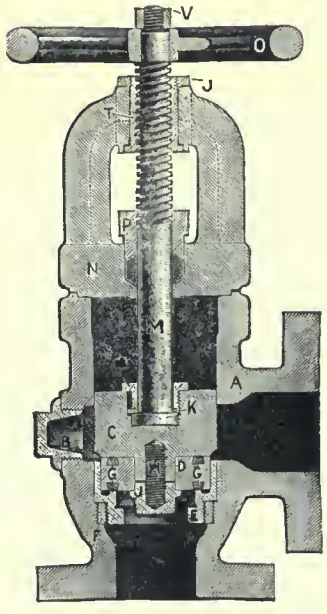
For the year ending June 30, 1906, a similar estimate would give a recovery value of $5.71 per ton and a working cost of $3.29, leaving a net profit of $2.42 per ton. On the year's output, the 1906 cost is equivalent to 8.35c. per lb. of copper, after deducting gold and silver recovery. With the higher metal quotations now prevailing and about the same working cost, the earnings of this company for 1907 will show an increase over all previous years.

FAULTS and plications are a measure of the shortening of the earth's circumference that has taken place in an orographic crisis. During the ages of preparation, the amount of shortening in the making of the geosyncline has been small, for the slowly accumulating strain reduces widths only by the difference between the shallow arc and its chord.

An Improved Blow-Off Valve.

Heretofore, in all makes of blow-off valves, the seat was so placed that as the disc approached it, there would be an accumulation of scale and sediment. The effect of this accumulation is to cut the bearing surfaces to such an extent that in a short time the valve becomes leaky. Various methods have been invented whereby the disc could be made to fit tightly in the valve-body, the object being to prevent the scale from passing onto the seat-bearing after the disc has passed and cut off the inlet. This method, however, proved unsatisfactory, as the valve soon became worn, and in a short time permitted the passage of scale and sediment. These defects have been overcome in the blow-off valve herewith illustrated. The plug fits snugly in a separate and easily removable bronze casing, which can be readily replaced when worn. Any accumulation of scale or sediment that might remain on the seat before the disc is brought in contact, is washed by the water that passes around the plug when seating.

In the sectional view, it will be seen that the plug *C* carries a reversible, double-faced disc *D*, secured to plug *C* by



stud *H* and nut *J*. This plug *C* is guided perfectly in the valve-body *A*. The bronze seat-ring *E* is screwed into a second brass ring *F*, the object being to make it possible to renew *E* easily in case same is worn. At the back of the valve is a plug *B*, the use of which is to permit the introduction of a rod to clean out the blow-off pipe when desirable. The stem *M*, which raises and lowers the disc *C*, is held in place by lock-nut *L*, which is prevented from unscrewing by non-rotating washer *K*. The threads of the stem *M* operate within the bronze bushing in the top of the yoke, which bushing can easily be removed. It will be seen from this description that all parts of the valve have been so designed that they can be easily renewed when worn or broken, the disc *D*, having two babbit-faced bearings *G G*, it can be replaced at small cost, or the user of the valve can melt out the old babbit and pour in new metal, and after this is faced off, the disc is as good as new.

This valve, known by the trade name of Duro, is constructed of the best materials and carefully tested. The Lunkenheimer company, which manufactures it, guarantees it to surpass, in durability, any other blow-off valve on the market.

Trade Treatises.

ALLIS-CHALMERS CO. issue Bulletin 1418, dealing with steel ventilating fans.

WORD BROTHERS, 60 Castro St., San Francisco, have issued a catalogue, which gives new data concerning their drill-maker and sharpener.

THE ATLAS CAR & MFG. CO. of Cleveland, Ohio, sends us Catalogue No. 1050, showing a variety of cars for mines, quarries, industrial railways, etc. This company also makes a complete line of electric cars, trucks, mining skips and buckets, track-switches, and other appliances.

THE HEWITT MACHINERY CO., of San Francisco, agents for the Atlas engines and boilers, announces that the Atlas company has been awarded a contract for an 8,300-h.p. plant of Atlas water-tube boilers, complete, for installation in the power stations of the Capitol and congressional buildings at Washington.

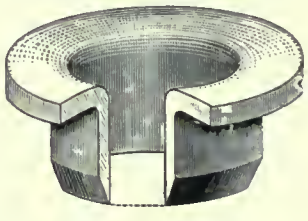
Commercial Paragraphs.

JAS. J. BROSSOIT, manufacturer of the Numa rock-drill sharpener, Salt Lake City, Utah, recently shipped one of his machines to the Tomboy Gold Mines Co. at Telluride, Colo. A number of these machines are in use in the large mines of Montana, Utah, Michigan, and Idaho.

WM. A. HEWITT, of the Hewitt Machinery Co., 37 Second St., San Francisco, has completed arrangements for the manufacture and sale of Lund's Drill-Maker & Sharpening Machine. This machine has been recommended and is in regular use in the Reclamation Service of the United States Geological Survey.

THE DEMING COMPANY.—This company originated under the name of the Silver & Deming Mfg. Co., and in 1880 they began the manufacture of hand and wind-mill pumps, hydraulic rams, etc. In 1890 the firm name was changed to The Deming Co. They were awarded the gold medal for pumping machinery in 1893 at the World's Fair. In 1894 they began the manufacture of their well-known Triplex and Deep Well pumps and this branch of their business has increased rapidly ever since. This company is prepared to handle any pumping problem using electric, steam, gasoline, or other power, and will send a complete catalogue on application to their home office at Salem, Ohio.

SPECIALIZATION in every line of manufacturing is the order of the day and the old way of patching up breaks, cutting packings from old belts or scrap and 'getting along' as best one can, is passing. It may surprise some to know that at Detroit there is a prosperous concern, THE DETROIT LEATHER SPECIALTY CO., manufacturers of the Wear Well brand of leather packings, which does not carry any stock to speak of and yet is kept busy making leather



Leather Flange Packing.

packings for machinery-users of all kinds. They make packings to order and are as particular in the selection of proper leather for specific purposes as in the manufacture of the packings. They can handle any kind of a leather-packing problem, and have made one flange-packing, which is 10 ft. 9 in. long by 4 ft. 1 in. wide. A comprehensive and exceedingly artistic catalogue has just been issued by them and will be sent on application to them at Detroit, Michigan.

THE testing plant of the GENERAL ENGINEERING CO., 159 Pierpont St., Salt Lake City, Utah, is being kept busy on various carload tests from Idaho, Nevada, and Colorado. This plant is automatic throughout and ores are treated under exactly similar conditions that they would encounter in actual practice. The plant consists in the main of the necessary crusher rolls, and Huntington mill, with trommels to screen to two sizes, Callow screens to screen from 16 to 120 mesh, with a screen ratio of two to one; four jigs; six Callow tanks; four Wilfley tables; one Callow-Neill slime table and one Kelly filter-press. This plant besides being equipped for concentration tests is so arranged that plate amalgamation and cyanide tests can be carried out either in conjunction with concentration or as separate tests. This company will be pleased to give prospective clients full information as to their terms for the different classes of tests upon application. J. M. Callow is president and general manager; James W. Neill, is vice-president.

Editorial.

THE OFFICES of the MINING AND SCIENTIFIC PRESS are now at 667 Howard St., San Francisco, and this issue is sent from the new address.

ACCORDING to the statistics tabulated by Henry R. Merton & Co., London, the total copper supplies in 1906 were 711,675 long tons of fine metal, as compared to 682,125 tons in 1905 and 479,514 in 1900. Of the total, the United States contributed 408,475 tons; Spain and Portugal, 49,320; Mexico, 60,625; and Australasia 36,250 tons. Thus the United States is responsible for over 57 per cent of the world's production.

SIGNS OF A TIGHTENING of the money market are apparent. In New York the necessities of speculators have been excessive and call rates are mounting. In San Francisco the supply of ready money is decreasing, for the insurance payments have been spent freely and reconstruction is making heavy demands on the local banks.

IT IS A PLEASURE no longer to have to write "temporarily at Berkeley, California" and to be able to announce that we have returned, after one year's enforced absence, to San Francisco. We are two blocks from Market St. and just east of Third St., so as to be conveniently near the financial district. We shall be glad to see our friends, to whom our new offices and composing room will seem a great improvement as compared to the restricted quarters occupied recently.

THE NEW HOME of the national engineering societies was formally opened on the 16th instant by Mr. Andrew Carnegie, who had given the $1,000,000 required for the construction of the building. The principal address was that of Mr. Arthur T. Hadley, the president of Yale University. On another page Mr. Charles S. Palmer gives some of his impressions of the occasion. It was a notable event and we trust that it may mark the beginning of a new era of enlarged usefulness on the part of the important engineering organizations to which the building will serve as headquarters.

WE NOTE that college publications, in referring to appointments obtained by alumni, often overstate the nature of the position held, so that young fellows who are doing subordinate work in a cyanide plant are described as "in charge" and assistants to surveyors are labeled as "engineers" to the company. The idea is to prove that the graduates get important positions immediately they begin their career. This is a mistake, it puts the men mentioned in the position of claiming a status to which they have not attained and it throws doubt on

other items given by the same journals. The first evidence of college training should be scientific accuracy, not the irresponsible falsity of the daily press.

Undesirable Citizens.

THE letter addressed by the President to a certain unfortunate at Chicago will ring like a bugle call across the width of this continent. Mr. Roosevelt has justified himself in characteristic fashion. While the judicious may have grieved that he should make a disparaging reference to men under trial, it is apparent that his refereuce did not touch upon the acts for which they are being tried, but to the pestilent activities to which their lives have been devoted. There may be room for criticism of the President even now, as there is for many of the impulsive things that he does, but it is the essential manliness of his position and the fact that he speaks for American citizenship at its best that will delight the readers of this last utterance of his. We take pleasure in re-printing his letter in full on the next page.

To those engaged in mining, the series of events that have preceded the trial of Moyer, Haywood, and Pettibone is familiar. They are officials of an organization that has defied the law and fomented industrial unrest. Whether they are guilty of the particular acts for which they are indicted, remains to be proved. If guilty, they will be punished according to law; if not guilty, the State of Idaho will owe them a full reparation. It is unfortunate that any idea should prevail that these men are not to have a fair trial. We know of no reason for such a conclusion. When the law starts in motion it may seem to the friends of the suspects that it is vindictive and to a certain extent it becomes an action of the people against the individual. Because certain mine operators have been the avowed enemies of the suspects there is no sufficient basis for inferring that the law is taken in their interests. No; it is done for the people—in a legal and in a civic sense.

When the events in Idaho began to attract attention, the lodges of the labor unions wrote to Mr. Roosevelt, protesting against the proceedings taken against the three leaders of the Western Federation of Miners. The President gave offense by ignoring the many letters he received and by taking no action in the case. Meanwhile meetings were called in many of the large cities to influence public opinion in favor of the suspects, and those who organized these affairs went so far as to post notices all over the country, headed with the statement that "the only crime" of these men was "loyalty to their class." Great efforts have been made to represent the three labor leaders as victims of a conspiracy of capitalists, and resolutions to this effect have been passed at conventions of the Western Federation of Miners. The fact is, this whole labor controversy, in so far as it is a vendetta between capital and labor, is abhorrent to thoughtful men; it is only when the laws of the country are outraged and popular government is undermined that the community awakens to the need for curbing both sides. Most of our readers will appreciate the President's characterization of labor agitators as undesirable citizens and as the foes of their own order, but we take equal satisfaction in reading his classification of such men as Harriman. Capital and labor can well afford in these days to shake hands in sympathy and voice a joint regret that they should have for spokesmen such fellows. Moyer and Harriman both stand for incivism, that is, the opposite of what constitutes a good citizen. They represent industrial piracy. To most of our readers the incitement to disorder and the enmity to property rights, voiced by Moyer, are obviously bad, but to us the wrecking of a railroad company and the misuse of millions for speculative purposes by Harriman are eqnally to be condemned. Both are, in effect, anarchists.

Salve Atque Vale.

PARTICULAR interest attaches to the editorial page of the last issue of *The Black Hills Mining Review*. One editor bids farewell, and the other salutes his readers; but such changes happen usually for causes less notable than those mentioned in the present instance. The outgoing chief in his valedictory says that he has heard the "call of Nevada," and he answers it with alacrity, for he leaves "in a few days." He believes the Black Hills to be "a great mining camp," but he considers that Nevada is even better, and that it offers the greater opportunity. Then comes the salutatory of the new editor, who affirms his faith in the mineral wealth of the Black Hills, and expresses his belief that Nevada offers no better chance for profitable mining. To him it appears certain that the Black Hills will be "a good mining country, and a good place to live in, long after the present boom camps of Nevada have exhausted their ore supplies." All of which is interesting, because it is intensely human. Our sympathies, we confess, are with the new helmsman who is to steer the *Mining Review*, although we admire the energy of the gentleman who is obedient to the call of the desert, in fact, we hope both may succeed, and that it will be a subject capable of dispute, two years hence, whether the Black Hills or Nevada is the better region. For the moment, we remember that water-tanks are far apart in the desert, the wild cat is rapacious, and the booster is rampant. The Black Hills is a pretty good place for a home, and it has a hole in the ground called the Homestake, that has prodnced gold in large quantity for thirty years, and gives assurance of doing so for thirty years more. In contrast is the Mohawk, which produced $50,000 per day for 100 days, and made the fortunes of several men in the course of six months. And then there is that nameless grace, the charm of the unknown. The "call of Nevada" is a lure to the adventnrous, to those who can see gold mines just beyond the next range of hills, to those to whom it ever appears that the oxen farthest from home have the biggest horns. Without such men mining would shrivel to a petty business; we need the men of large hope and superfluous energy. We need also the conservative man, not easily enticed by the vagrant flames of speculation, the man that will not take his hand from the plough nntil the furrow is made. So here's luck to both of the editors!

By the Way.

It will be known to our readers that the President has been criticized for referring to Moyer and Haywood as "undesirable citizens," for these officials of the Western Federation of Miners are under trial at Boise City, Idaho, charged with responsibility for the murder of Governor Stennenberg of Idaho, and for other crimes in Colorado. The chairman of the Cook county Moyer-Haywood conference, at Chicago, wrote to Mr. Roosevelt, objecting to his remark, and the President replied in a letter, which we publish in full herewith:

"Dear Sir—I have received your letter of the 19th instant, in which you inclose the draft of formal letter which is to follow. I have been notified that several delegations bearing similar requests are on the way hither. In the letter you, on behalf of the Cook county Moyer-Haywood conference, protest against certain language I used in a recent letter, which you assert to be designed to influence the course of justice in the case of the trial for murder of Messrs. Moyer and Haywood. I entirely agree with you that it is improper to endeavor to influence the course of justice, whether by threats or in any similar manner. For this reason I have regretted most deeply the action of such organizations as your own in undertaking to accomplish this very result in the very case of which you speak. For instance, your letter is headed "Cook County Moyer-Haywood-Pettibone Conference," with the head lines: "Death cannot, will not, and shall not claim our brothers." This shows that you and your associates are not demanding a fair trial or working for a fair trial, but are announcing in advance that the verdict shall only be one way, and that you will not tolerate any other verdict. Such action is flagrant in its impropriety, and I join heartily in condemning it.

But it is a simple absurdity to suppose that because any man is on trial for a given offense he is therefore to be freed from all criticisms upon his general conduct and manner of life. In my letter to which you object I referred to a certain prominent financier, Mr. Harriman, on the one hand, and to Messrs. Moyer, Haywood, and Debs on the other as being equally undesirable citizens. It is as foolish to assert that this was designed to influence the trial of Moyer and Haywood as to assert that it was designed to influence the suits that have been brought against Mr. Harriman. I neither expressed nor indicated any opinion as to whether Messrs. Moyer and Haywood were guilty of the murder of Governor Steunenberg. If they are guilty they certainly ought to be punished. If they are not guilty they certainly ought not to be punished.

But no possible outcome either of the trial or the suits can affect my judgment as to the undesirability of the type of citizenship of those whom I mentioned. Messrs. Moyer, Heywood and Debs stand as representatives of those men who have done as much to discredit the labor movement as the worst speculative financiers or most unscrupulous employers of labor and debauchers of legislatures have done to discredit honest capitalists and fair-dealing business men.

They stand as the representatives of these men, who by their public utterances and manifesto, by the utterances of the papers they control and inspire, and by the words and deeds of those associated with or subordinate to them, habitually appear as guilty of incitement to, or apology for, bloodshed and violence.

If this does not constitute undesirable citizenship, there certainly would never be any desirable citizens. The men whom I denounce represent the men who have abandoned that legitimate movement for the uplifting of labor, with which I have the most hearty sympathy; they have adopted practices which cut them off from those who lead this legitimate movement. In every way I shall support the law abiding and upright representatives of labor, and in no way can I better support them than by drawing the sharpest possible line between them upon the one hand, and on the other hand those preachers of violence, who are themselves the worst foes of the honest laboring man.

Let me repeat my deep regret that any body of men should so far forget their duty to their country as to endeavor by the formation of societies, and in other ways to influence the course of justice in this matter. I have received many such letters as yours. Accompanying them were newspaper clippings announcing demonstrations, parades, and mass meetings designed to show that the representatives of labor, without regard to the facts, demand the acquittal of Messrs. Haywood and Moyer, when such meetings can, of course, only be designed to coerce Court or jury in rendering a verdict, and they, therefore, deserve all the condemnation which you in your letter say should be awarded to those who endeavor improperly to influence the course of justice.

You would, of course, be entirely within your rights if you merely announce that you thought Messrs. Moyer and Haywood were 'desirable citizens,' though in such case I should take frank issue with you, and should say that, wholly without regard to whether or not they are guilty of the crime for which they are now being tried, they represent as thoroughly an undesirable type of citizenship as can be found in this country—a type which, in the letter to which you so unreasonably take exceptions, I showed not to be confined to any one class, but to exist among some representatives of great capitalists, as well as among some representatives of wage workers.

In that letter I condemned both types. Certain representatives of the great capitalists in turn condemned me for including Mr. Harriman in my condemnation of Messrs. Moyer and Haywood. Certain of the representatives of labor, in their turn, condemned me because I included Messrs. Moyer and Haywood as undesirable citizens together with Mr. Harriman. I am as profoundly indifferent to the one condemnation in one case as in the other. I challenge as a right the support of all good Americans, whether wage-earners or capitalists, whatever their occupation or creed, or in whatever portion of the country they live, when I condemn both the types of bad citizenship which I have held up to reprobation. It seems to me a mark of utter insincerity to fail thus to condemn both and to apologize, for either robs the man thus apologizing of all right to condemn any wrong-doing in any man, rich or poor, in public or in private life.

You say you ask for a 'square deal' for Messrs. Moyer and Haywood. So do I. When I say 'square deal' I mean a square deal to everyone; it is equally a violation of the policy of the square deal for a capitalist to protest against denunciation of a capitalist who is guilty of wrong-doing, as for a labor leader to protest against the denunciation of a labor leader who has been guilty of wrong-doing. I stand for equal justice to both, and so far as in my power lies I shall uphold justice, whether the man accused of guilt has behind him the wealthiest corporations, the greatest aggregation of riches in the country, or whether he has behind him the most influential labor organization in the country."

SMELTING IN BRITISH COLUMBIA.—At the Granby smelter, in British Columbia, the analysis of charge is: Silica, 38½%; lime, 20%; and iron oxide, 23%. With a high matte-fall and driving fast, the 20-ft. furnaces put through from 700 to 800 tons of ore per diem. While running to higher grade of matte the capacity ranges between 600 and 700 tons daily.

Personal.

F. L. BOSQUI is in Arizona.

MARK L. REQUA is at Ely.

R. A. F. PENROSE is in South America.

ALGERNON DEL MAR is now at New York.

WALDEMAR LINDGREN is in San Francisco.

ARTHUR TAYLOR has returned to London from India.

C. S. THOMAS, of Denver, was in San Francisco this week.

J. R. FINLAY has changed his office to 2 Rector St., New York.

J. MORGAN CLEMENTS is examining mines in the Butte district.

L. W. WICKES is manager of the Ely-Witch mine at Ely, Nevada.

ELMER M. BRAY is visiting San Francisco from Hillside, Arizona.

W. P. HAMMON has returned from New York to San Francisco.

ALEXANDER MAITLAND, of Negaunee, Mich., is in San Francisco.

AUGUSTE MATHEZ has been examining mining methods in Wisconsin.

W. JUDSON is in San Francisco on his way from Butte to the Argentine.

DONALD DUNCAN is with the Tres Amigos mine, at La Junta, Costa Rica.

J. M. RICHARDS, recently assayer for the East Butte Co., has gone to Goldfield.

R. C. RUCKER is superintendent of the Pirita mine, near Alamos, in Sonora, Mexico.

JAMES W. ABBOTT has been examining mines at Bingham, Utah. He is now at Pioche.

FOSTER WILLIAMS is superintendent of the Pinguico M. & M. Co. at Guanajuato, Mexico.

THOMAS COX is general superintendent for the Steptoe Valley M. & S. Co. at McGill, Nevada.

V. B. SHERROD is superintendent of construction for the Tajo de Dolores Mining Co. at Guanajuato, Mexico.

C. W. WHEELOCK, of New York, is on a visit to San Francisco, incidental to professional work in Nevada.

D. W. BRUNTON is in Japan, on his way around the world, taking a well-earned rest from professional work.

NORMAN C. STINES is on his way from Los Angeles to Trinity county, to take charge of the Yellow Rose mine.

ELISHA HARRIS is superintendent for the Guanajuato Amalgamated Gold Mines Co. at La Luz, near Guanajuato, Mexico.

RICHARD PEARCE sails from New York on May 8, on his way from Colorado to Cornwall, where he will spend the summer.

H. S. LEACH is superintendent of construction for the Guanajuato Development Co. and the Peregrina M. & M. Co. at Guanajuato, Mexico.

MALCOLM MACLAREN, late mining specialist to the Government of India, passed through San Francisco, on his way from Calcutta to London.

G. A. RICHARD, the general manager of the Mt. Morgan mine, in Queensland, is expected on a visit to the United States. He comes to study electrolytic methods.

L. VOGELSTEIN & Co. of New York, give the figures of German consumption of foreign copper for the months of January and February, 1907, as follows:

Imports of copper	17,294 tons
Exports of copper	1,250 "
Consumption in January and February	16,044 tons

As against consumption during the same period in 1906 of 20,251 tons. Of this quantity, 13,698 tons were imported from the United States.

Obituary.

CHARLES C. SWART, for fourteen years in charge of the advertising and catalogue business of the Gates Iron Works, Fraser & Chalmers, and the Allis-Chalmers Co., of Chicago, later occupying a similar position for over two years with the Union Iron Works, and for the past year with the Fulton Iron Works, San Francisco, died in St. Luke's Hospital, in this City, on April 9, the result of an operation for appendicitis. Mr. Swart was acknowledged by all commercial artists in the West as the peer in air-brush work, especially on machinery drawings; his knowledge of machinery, particularly in the mining line, enabled him to construct from working drawings copy that could not be distinguished from photographic work in halftone productions. He was the pioneer in air-brush work in San Francisco, and his work is wellknown among machinery builders in this City, and on the Pacific Coast. His last work, the 'Gold and Silver Milling Machinery' catalogue, just published by the Fulton Iron Works, which he wrote and illustrated, is considered by mining experts and others as the most complete and best illustrated book treating on these subjects published. Mr. Swart was a genial man to meet, and, while particular in his work, was well liked by acquaintances and others with whom he came in contact. He leaves a widow, son, and two daughters to mourn his loss.

Mining Summary.

ALASKA.

KETCHIKAN DISTRICT.

A drift has been started on the Mamie to cut the new ore-body which was proved by the diamond-drill. Exploration work with the diamond-drill is being continued at other points in the mine.——The Mt. Andrew company shipped 4,500 tons last month. An additional five-drill compressor has been ordered. The 165-ft. level is the main working level at present, but the shaft will be sunk at once.——The Niblack shaft will be sunk another 100 ft.——It is reported that the Hadley smelter will soon start, and will have on hand a sufficient supply of coke and ore to insure a long, continuous run.——There seems to be some hitch in the plans for the reorganization of the Alaska Copper Co., and but little is being accomplished at the mine or smelter at Copper Mtn. The Rush and Brown mines are idle, with 20,000 tons of shipping ore on the dump, and this state of affairs is due to the failure of the Alaska Copper Co. to ship the product, although it has a lease on the mine.——At the Valparaiso mine, a surface tramway is in the course of construction, from the mine to the beach in Johnson's inlet.

NOME DISTRICT.

In addition to the stamp-mill that will be erected in Nome this summer, there will be a small mill in operation at the head of Snake river. At first there will be but three stamps in the latter mill. C. F. Jameson and J. M. Conley are the owners.—— A good strike has been made on Centre creek, on the No. 4 Vogel & Williams claim. The dirt is 10 ft. thick, and will average 15c., which should pay handsomely.—— A rich strike has been made on a tributary to Coffee creek. Four feet of gravel running 30c. to the pan is reported.—— Ford & Cooper made a good strike on McDonald creek while sinking on a fraction adjoining the Big Chief claim.

ARIZONA.

COCHISE COUNTY.

At a recent meeting of the stockholders of the Tombstone Consolidated Mines Co. the officers were all re-elected. The most significant action taken at the meeting was the order to amend the articles of incorporation, changing the provisionary bonded indebtedness to $5,000,000. This is understood to mean that the company will be forced to increase its issue of bonds, which bear interest at 6% and are underwritten by the Development Co. of America. It is reported that the former issue was for $3,000,000 and that this amount has been spent, making a greater bonded indebtedness necessary. The water problem has been much more serious than was anticipated at the time of the consolidation, and, while moderate ore shipments have been maintained, the ore has been quite low in grade, and the chief source of supply has been the old stope filling left by the former operators.——At Bisbee, many of the men are returning to work at the various shafts, and the union pickets are having but little success in soliciting new members. Over 2,000 men were at work the first of last week, and the number is daily increasing. The union parade showed a strength of about 700 men, although it is claimed that 1,300 men attended the big meeting. Many of the union men are leaving the camp, while non-partisan miners are coming in from all the outlying camps to get work in Bisbee.—— It is reported that the election of C. H. Dodge, of the Phelps-Dodge company, to the directorate of the Greene-Cananea was accomplished to aid in getting better rates on lumber for the Phelps-Dodge properties, which spend from two to three million dollars per year on lumber. Heretofore they have bought lumber from Puget Sound, but it is expected that now much of it will come from Chihuahua, where the Sierra Madre Lumber Co. is operating.——The smelter at Benson has changed hands, the Southwestern Smelting Co. having transferred it to the Boston & Arizona Smelting Co., a corporation of Nevada.——There is activity in the camp of Johnson. The Bonanza Bell Co. is employing 40 men and the shaft is being sunk. The Cochise shaft is over 400 ft. deep. Work has been temporarily suspended at the Copper Chief, the shaft of which is 200 ft. deep. The new hoist has been received at the Republic property.

GILA COUNTY.

(Special Correspondence).—Attention is turning to some of the old silver mines at Globe, which were noted for their output of the white metal 30 years ago, and were abandoned because of the precipitate decline in the price of silver, and high operating costs. Among the richest of the mines were the Stonewall Jackson, Hannibal, R. E. Lee, and Little Mack, situated at McMillen, 20 miles east of Globe, and its strong rival in 1876-78. These old properties, together with a number of other claims, 32 in all, have been taken over by a strong company of Globe men organized by V. Y. Smith. The name of the new company is the McMillen-Stonewall Mining Co., capitalized at $1,000,000, with shares of $1 each. The property has a length of three miles on the Stonewall Jackson lode, which varies in width from 40 to 100 ft. The Stonewall Jackson mine was worked by the old company up to 1883 and one claim is reported to have produced $500,000. Later, lessees took out about $100,000. The Hannibal mine yielded $50,000; R. E. Lee, $35,000, and Little Mack, $60,000. The workings on all these mines are shallow, the Little Mack being only 75 ft. deep. The shaft on the Stonewall Jackson was sunk to 600 ft., but no ore was stoped below 230 ft. The shaft was in ore all the way down and there was high-grade ore in sight when the mine was abandoned and partially filled with water. The company's mill had only five stamps, and no ore running less than 50 oz. was milled. Some ore was sent to Yuma by wagon, and thence to San Francisco.——The Stonewall Jackson is one of the best defined fissure veins in the county, and besides its value in silver, shows indications of copper in many places on the surface. Some preliminary work has recently been done, most important of which was the construction of a good wagon road from Rice Station on the G. V. G. & N. railroad to the mine, 22 miles distant. Grading has commenced for a three-compartment shaft to be sunk 1,000 ft. A 16 by 20 in. Hendrie & Bolthoff steam-hoist and two pumps are expected soon, and a cross-compound Rand compressor with a capacity of seven drills. Sinking the shaft began last week. The officers of the new company are V. Y. Smith, president; and H. L. Coombs, treasurer.

Phoenix, April 23.

GRAHAM COUNTY.

The Arizona Copper Co.'s output for March was 1,372 tons of bessemer copper, while the Shannon Copper Co. produced 740 tons.——A petition has been circulated in Morenci and Longfellow asking for an increase of 50c. per day in the wages of all Americans and Mexicans employed by the Detroit, and the Arizona copper companies.

MOHAVE COUNTY.

The Deluge Wash mill, which has been erected at the old Berkeley mine, is ready to start, but sufficient fuel is not yet available.——At a depth of 300 ft. in the Standard Gold M. Co.'s property the vein is still holding and carries gold and copper.——Thomas Brayil reports the sale of the Lucky Boy mine to English people, and a smelter will be erected at Kingman. The company will also develop the Arizona-Goldfields mines, south of Kingman.——Good progress is being made on the 20-stamp addition to the Quartette mill, and it will be running within two months.——A good strike of silver ore is reported in the winze in the north tunnel of the Treasure Hill M. Co. A hoist will soon be in place and a pumping plant will be necessary.——A rich pocket has been encountered at the 60-ft. point in the Holy Moses mine.——The Gold Road shaft is down 800 ft. and a station is being cut at that point. The shaft will be continued at once, to the 900-ft. level. Changes in equipment at the mine and mill are probable.

YAVAPAI COUNTY.

The Crown King mine is again to be a producer, after having been tied up in litigation for several years. Sufficient funds have been raised to finance it. This property is supposed to have produced $2,000,000 before it was closed, and paid $300,000 in dividends. Charles Broan will be the

superintendent; Lewis J. Link is president of the company, and Edwin T. Gillespie is treasurer. The tunnel is now 2,400 ft. long, the face having a depth on the vein of 600 ft. The main shaft is 500 ft. deep, and will be sunk at once to the 700-ft. point, from which a drift will be run on the vein, underneath the old bonanza stopes. The mill has a capacity of 120 tons per day, and concentrates will be shipped to the Humboldt smelter. The company owns a group of 60 claims.

CALIFORNIA.

NEVADA COUNTY.

The Sultana mine has been unwatered, and work has begun there. The task of pumping this mine dry has been an arduous one, requiring several weeks, the trouble originating in the failure of power during the heavy storms of the winter.—— Three shifts are working at the Posey Canyon gravel mine. The tunnel is being driven, and will reach the gravel bed in the ancient river channel within six weeks. The property lies three miles northwest of Grass Valley.—— There are over 300 men on the payrolls of the mines of Nevada City and territory immediately adjacent. This force is distributed among the different properties as follows: Champion, 100 men; Murchie, 40; other Willow Valley mines, 40; Union, 12; Blue Tent, 12; Mountaineer, 20; Oustemah, 14; Union Hill, 12; Charonnat, 10; Indian Flat, 10; miscellaneous, 40. Total, 310 men.

SHASTA COUNTY.

The Stauffer Chemical Co. has bonded a group of eight claims, in the Lower Springs district, of E. P. and J. C. Conner. The working bond will run for 18 months, and an attempt will be made to save the copper and gold content. ——George Payne has succeeded N. W. Keith as superintendent of the Mad Ox mine on Whisky creek. This is a part of the Cariboo holdings, the principal property being in the Salmon River country of Siskiyou county.——Work is progressing on the Shasta mine extension of the tramway to the Balaklala terminal.

Development work is progressing at the Yankee John mine, near Centerville. This property was sold by John Reese to Pittsburg people. A shaft has been sunk 100 ft., and cross-cutting to the vein has started.—— Ore is transported from the Shasta King mine to the head terminal of the Balaklala tramway by an inclined skip, the track having an angle of about 45°.—— The Bully Hill company is pushing work on its mine development, smelter revision, and the construction of the broad-gauge railroad up Pitt river from Kennet. John B. Keating, formerly of Helena, is the manager.

SISKIYOU COUNTY.

The Queen of Sheba mine on Patterson creek has been equipped with electric machinery for mine operation.—— J. Wade has finished prospecting with churn-drills at Oro Fino, in the interest of the company operating the Callahan dredge, and prospecting has started on Indian creek, near the old site of Hoopeville.——The New York mine, on Indian creek, near Fort Jones, has been taken over by a reorganized company which will be known as the Big Moose Mining Co. An electric plant will be erected, and the shaft sunk 1,000 ft.——About 30 men have been working on the flats at Hawkinsville since the first of the year, and a good run is expected.——The St. George Hydraulicking Co. has had its giant at work for three months. The property of this company includes 140 acres, together with the upper Greenhorn ditch and all the waters of Canal gulch. ——The Robert Sylvester Mining Co. has uncovered a large area of bedrock and expects to make a good clean-up.—— There is much activity on Scott bar, now that the stormy weather is over. The Gold Point Mining Co. is driving a tunnel to tap the old Magoffey channel. The tunnel is in 200 ft. and no bedrock has been struck.——An important strike is reported on the First National property in the Blue Ledge district. In driving a cross-cut at a depth of 150 ft., a good vein of copper ore was encountered.——Attention is being attracted by the discovery of a lode of copper ore at Yellow Butte, north of Mt. Shasta.——A fine body of ore has been encountered on the 300-ft. level of the Morrison & Carlock mine, in Quartz valley, 40 men are employed, and the 10 stamps drop steadily the year around.

There are two tunnels and a shaft on the Ten Lakes mine, of which C. S. Osborn is manager. Work has been going on all winter in one of the tunnels and a vein 50 in. wide is being developed.——The wrecked aerial tram between the Bonanza King mine and the mill has been repaired. Joseph Porter, the superintendent, states that the mill will soon be running. This is the mine that was bonded to the Treadwell Brothers, of Alaskan fame. About $200,000 has been spent in surface improvements alone.——The people of Hornbrook are excited over the discovery of gold about four miles northwest of the town.——A third giant has been put in operation on the Quartz Hill mine at Scott Bar. L. D. Crawford is the superintendent.

Final payment of $70,000 has been made by Henry E. Wood of Denver, on the Advance mine, situated beeween Etna Mills and Sawyer's Bar. The property formerly belonged to A. C. Brokaw. The small mill will be enlarged and equipped with electric power.

Development is progressing at the Advance mine, and the mill is running steadily. A compressor and electric power will soon be added to the equipment.—— The Homestake company is driving the cross-cut adit and expects soon to reach the lode.—— The Sheba mine will soon have electric power. This property will be operated extensively this year under the supervision of Noel E. Graves.—— Most of the men employed at the Grouse Creek hydraulic mine, near Callahan, have quit work, because the working hours have been increased from nine to tenhours.

Over 500 men are employed in the Blue Ledge copper mining region, in the Elliott Creek district. This new mining district extends all along the Oregon border, and down to the Klamath river at Oak Bar.—— The Patterson Creek Mining Co., operating the Sheba mine in Scott valley, has levied another assessment of 10c. per share for further development work.—— The Mono mine, at Humbug, has been sold to C. C. Broadwater, of Montana. William Forstner made the examination. This mine has been worked for several years, and is well equipped.

TRINITY COUNTY.

A good strike is reported in the Golden Jubilee mine, on Coffee creek. This property is owned by a Santa Rosa company, and W. L. Chapman is the superintendent. Several good finds have been made at this mine, and a 10-stamp mill is nearly completed that will take the place of the Huntington mills that have been used. Thirty men are employed, and more will be put on as soon as the new mill is running.

COLORADO.

BOULDER COUNTY.

The milling plant of the Good Luck M. & M. Co., on Sugar Loaf Mtn., is being enlarged.——The Taylor Gold M. Co. is erecting a 20-ton cyanide plant at Magnolia.——The first clean-up at the Wano mill at Jamestown is reported as satisfactory.——The Annuity company, operating on Sugar Loaf Mtn., has recently installed a new type of concentrating tables in the mill.

CLEAR CREEK COUNTY.

The Mendota properties are producing more ore than they have for several years. The Jewell mill is making good lead, zinc, and iron concentrates from the dumps of the upper workings, and the Mendota mill, operated by Stephens & McGrath, is working the dump material at the portal of the Victoria tunnel. The task of unwatering the lower workings on the Mendota lode is about completed and sinking will soon start.——The tramway for conveying ore from the Mammoth mine in Brown gulch, to the railroad track has been completed, and shipments will be made at the rate of two cars per day, to the concentrating mill at Dumont. Dan J. Williams is the manager.——The Nashotah mill has not been running for a few days, as repairs are being made. A new Chilean mill will be added.——The Terrible mill has started again, a sufficient supply of water now coming down the creek.

GILPIN COUNTY.

At a point 250 ft. from the portal of the Gold Run tunnel, a drift has been run on the vein for 160 ft. This property is

owned by the Union Exploration Co. of New York, and is situated near the head of South Boulder creek, near where the proposed tunnel of the Moffat railroad will penetrate the range.——An engine is being installed at the Mtn. Monarch mill in Gambell gulch, for hoisting ore up the incline from the tunnel, and it is expected that soon the mill will be running night and day on ore from the tunnel property.——A good vein has been cut in the tunnel of the Golden Rod company. Contractors have just finished 200 ft. of tunnel work, and have started on a new contract.——Work will soon be resumed on the property of the Jenny Creek M. & M. Co., which is composed largely of Pittsburg men. A mill will probably be built.

OURAY COUNTY.

The Atlas mill of 10 stamps will be enlarged to 20 stamps this summer. A new compressor has recently been installed and machines are used in stoping.——A force of 16

California.—Showing Position of the Counties.

men is employed at the Thistledown, and a raise is being run to connect the upper and lower workings. M. L. Thistle is the manager.

SAN JUAN COUNTY.

The main cable of the Aspen tram is in place and the line will soon be working. The lower tunnel is now in nearly half a mile on the vein.——The Grand Mogul mill is being enlarged, so that the capacity will be 200 tons per day, instead of one.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—A corporation will erect a plant on Big creek, southeast of Wardner, to supply the mines of that section of the Cœur d'Alene with electric power. Articles of incorporation are being drawn for the company, to be known as the Inland Power Co. The company will expend $300,000 on the building and equipment. It owns the right to a large volume of water from Big creek, and will be able to supply the mines with all the power necessary. The increase in mining operations in the Cœur d'Alene has caused a shortage of power.——The electric motor for the Frisco mine in the Cœur d'Alene is being installed. It will be operated by Spokane electric power and used principally to run the big pumps. The Frisco has recently resumed operations, after a prolonged shutdown. During this period the concentrator has been overhauled and it is expected that the Frisco will soon again take its place among the dividend producers of the Cœur d'Alene. One hundred and fifty men are employed at the mine and mill, and regular shipments are being made to the smelters.——The Frisco was a paying mine for years, several million dollars in dividends having been paid to its stockholders. At one time 400 men were employed. It has been opened to a depth of 2,000 ft. by a shaft. The cost of hoisting became so heavy that the mine was closed several years ago and the lower levels were allowed to fill with water. It was finally sold at sheriff's sale to satisfy a $100,000 mortgage, held by D. M. Hyman, of New York, and it was bid in by him. New orebodies have been uncovered and the future of the mine is promising. Gus Ehrenberg, of Gem, is the manager.——Albert Frank, representative of F. A. Heinze, is in the Cœur d'Alene to look over the ground and select a site for the concentrator of the Stewart mine, near Wardner.——Axel Swan and Thomas A. Roy have taken a $28,000 bond on the Military group of three claims in Military gulch, east of Burke. They will incorporate a company, and proceed with development work.——Preparations are being made by the management of the Lucky Calumet to install Spokane electric power early in May, when a five-drill air-compressor will be placed on the property in the Mullan district. The tunnel, driven by hand, is now in 400 ft. The Snowstorm vein and the National lode are believed to traverse the property. The National and Independent companies will also install electric power.——A foot of galena ore was found recently by Leonard and Carl Magnee in the tunnel in their property on Big creek, east of Wardner. The tunnel was driven 427 ft. years ago, and later the property was abandoned. Since the mine has come into the possession of the present owners they began retimbering the tunnel. It was while at the work that the ore was found. The foot-wall carries nearly two feet of talc, a promising indication in the Cœur d'Alene district.——Work has begun, under the management of Archie McCallum, upon the West Hecla group at Burke. This property was recently purchased by a Spokane syndicate and it is preparing to drive an 800-ft. cross-cut tunnel, which will tap the vein at a depth of 700 ft. The ground is situated near the Hecla mine.——J. H. Jackson, manager of the Cedar Creek group in the Cœur d'Alene, reports that a three-foot vein of white quartz and galena has been cut in the tunnel. The find was made 700 ft. from the portal. The ore runs 20% lead and six ounces silver per ton.——Kennedy J. Hanley, of Spokane, was awarded a verdict by the Supreme Court of the United States, giving him judgment for $125,000, due him as the proceeds of a one-eighth interest in the Skookum claim, one of the Federal group at Wardner, thus bringing to a close one of the most famous as well as bitterly fought mining cases in the Northwest, after eight years' litigation. The defendants are the Empire State-Idaho Mining Co.; Charles Sweeny, president of the Federal M. & S. Co.; and F. Lewis Clark, of Spokane.

Spokane, April 19.

(Special Correspondence).—Word from Grangeville states that a rich strike has been made in the Monument group, near Roosevelt. While the details are meagre, it is known that this strike is the result of three years of work on the Monument group.——At a recent meeting of the stockholders of the Jumbo, A. G. Wisner, of Lewiston, was elected manager of the mine, in place of Chris. Olson.——The Madrid claim in the Elk City district is being rapidly developed by the owner, Stanley Litchfield, who has driven the tunnel over 60 ft. He has struck some good free-milling ore in the dike, and expects to cut the lode at a distance of 100 ft.——The Butte capitalists, who some time ago purchased property in the Elk City district, have begun work on the Buffalo Hill placer claim.

Lewiston, April 20.

(Special Correspondence).—Stockholders of the Crooked River M. & M. Co. will meet at Orogrande, May 1, to consider forming a new company from the old. The plan is to create a new corporation with a capitalization of 600,000 shares of the par value of $5, in lieu of the present corporation with a capitalization of 1,500,000 shares, and to transfer the holdings of the present company to the new corporation. The directors have confidence in the property and believe that under the contemplated adjustment, means will be found for placing the property on a sound financial basis.

The company is the owner of the property formerly known as the Hogan, which has been a heavy produeer of gold. There is a large dike, which is quarried and conveyed to the mill.

Spokane, April 12.

NEZ PERCE COUNTY.

The Idaho company, a New Jersey corporation, operating a dredge at Pierce City, has just paid its first dividend, amounting to $10,000. Sixty per cent of the stock is owned in the East. H. M. Hare of Spokane is the principal Western stockholder. The company is incorporated for $100,000, owns 321 acres of land in the Pierce district, and it will require 18 years to work the ground.

NEVADA.

NYE COUNTY.

(Special Correspondence).—The West Extension mine has made a strike in the west drift, 100 ft. from the shaft, at a depth of 250 ft. Some of the ore runs well in gold, silver, and copper. Some ore has been sacked for shipment. The veins of the West Extension are improving toward the west, and the principal work is in that direction.—— Work on the Bullfrog Teddy is progressing and some ore has been discovered. The mine adjoins the West Extension, and gives indications of containing the same kind of ore. New machinery is being installed.—— A strike is reported from the 300-ft. level in the Mayflower Consolidated, the ore assaying $26 per ton, which is not rich enough to ship to the smelter, but can be profitably handled on the ground, when milling facilities are provided.—— Nine oil claims, comprising 600 acres, have been located six miles south from Rhyolite, on the Tonopah & Las Vegas railroad. Boring machinery has been ordered from Los Angeles by the locators.—— Work at the Victor mine is progressing, and a vein of quartz is being developed. The immediate country is being opened by drifts and cross-cuts.——Good progress is being made in the development of the orebody in the Tramp Consolidated, and some ore has been taken out.——This city is lively, and the Stock Exchange is doing a good business.—— Local mining men do not anticipate the spreading of labor troubles to this district, as employers and employees are on very friendly terms.

Rhyolite, April 18.

TEXAS.

PRESIDIO COUNTY.

The Presidio Mining Co., which has been operating a pan-amalgamation mill at Shafter for 20 years, has decided to change the process to cyanidation. Recent tests showed the horn silver to be extremely soluble in cyanide solution. F. L. Bosqui is designing a cyanide plant for this company to take the place of the pan-mill.

WASHINGTON.

COWLITZ COUNTY.

An electric railroad may be built from Castle Rock to the St. Helens mining district, 55 miles. The right of way has been secured, also water-rights and terminal facilities at Vancouver and Portland. Twelve miles of road is being used as a logging road. Work on the rest will be begun at once, and finished as speedily as possible. The route is up Green river into the heart of the Cascades. It is the purpose of the company to eventually build the road into Vancouver, then east to Mount St. Helens, tapping a rich lumber district, then back to the mountains, making a complete loop. Besides the mineral region which the road will open, it will tap one of the greatest timber belts in Washington.

FERRY COUNTY.

(Special Correspondence).—The Republic mine was sold for taxes, after paying $650,000 in dividends. The main orebody, which was followed from the cropping downward, pinched out at a depth of 616 ft. The vein-quartz, either side the pay-shoot on the 604-ft. or No. 4 tunnel level, is 53 ft. wide and too low grade to be valuable. But between that level and the surface are numerous small deposits of high and medium-grade ore included in the vein material.——An Act, providing for the Commissioners of the several counties in Washington leasing mines which had been sold for taxes, passed the last Legislature and became a law.——The dry ores from the various mines of Republic have always been sold at distant smelters under contract, according to the demand, and were generally used for converter linings in copper smelting. The Quilp, Pearl Consolidated, San Poil, Black Tail, Ben Hur, North San Poil, Trade Dollar, and other mines of the camp productive of dry ores were closed down, one after another, on account of the companies not having a market for or means of treating, the ores.

During the past two months these mines have been leased to Harry L. Rodgers, who is said to be representing Montana and New York people with ample capital, and he is promoting a scheme to consolidate these mines and work them on an extensive scale. With each lease he has taken an option to purchase, the royalty to be paid on the lease to apply on price of the mine. The Montana people who are behind him have invented a new process, unknown to any others, and they claim the ability to successfully treat the ores for less than $3 per ton, by using warm compressed air in rapidly revolving cylinders and afterward cyaniding in specially patterned tanks. Mr. Rodgers, who is not a practical millman, could not sufficiently explain the process for a lucid description, but told the writer that the people in Montana had thoroughly tested the Republic ores and were satisfied they could make their claims good.

D. W. Rathfon, a practical millman, who had charge of the Drum-Lummon mill, in Montana, for a number of years and conducted the experiments on the dry ores from the Republic camp mines, at the Mountain Lion mill, has openly stated that he can treat them for less than $1 per ton and effect a saving of 80% principally by concentration. As these experiments were conducted privately, and Mr. Rathfon has never divulged his method, it is only known to himself, the men who assisted him, and the superintendent of the Mountain Lion mine and mill. Mr. Rodgers has agreed with the mine owners to begin building a mill of not less than 100 tons daily capacity before July 1, and he will start work for a 500-ton mill within two months after effecting a consolidation of the mines.——The smelter plant at Keller camp has been completed, and the equipment is reported to be faultless, but coke for fuel can only be had by wagon haulage 26 miles from the nearest railway. The plant will therefore be hung up until a railway is built from Republic to Keller, a distance of 51 miles.

Republic, April 19.

LEWIS COUNTY.

The Ivanhoe M. Co., which owns a group of 13 claims near the Cowlitz pass, west of Spokane, has purchased four additional claims. The company is now working on a five-foot sheet of zinc, assaying 40%. The ore is stripped for 1,800 ft. A 10-ton zinc smelting plant and an electric plant will be installed at once.

OKANOGAN COUNTY.

Stockholders of the Trinity G. & S. M. Co., owning three claims near Oroville, Wash., have elected these officers: President, Edward Davis; vice-president, Martin Silver; secretary, M. Eilers; treasurer and general manager, W. H. Hicks. Plans are being made to send electric power into the mine, and to build a wagon-road from the property to the railroad, 1¼ miles.

STEVENS COUNTY.

(Special Correspondence).—The Napoleon group, consisting of 46 claims in Pierre Lake district, belongs to the British Columbia Copper Co., which has completed plans for a 500-ton cyaniding plant, to be established on the Kettle river, two miles from Boyds station, on the Washington & Great Northern railway, to treat a body of iron oxide ore about 1,000 ft. long and 500 ft. wide and developed to a depth of 150 ft. The whole mass is reported by the management to have an average value in gold of $9 per ton. The company has a six-drill compressor-plant which will be increased to a 10-drill equipment. A steam-shovel will be used for removing the ore to self-feeding bunkers, whence an aerial tramway, a mile in length, will be constructed for conveying the ore to the mill. A spur will be built by the railway company one-half a mile from Boyd's station to the mill.

Republic, April 19.

G. A. King is in charge of the Spokane lead mines in Metaline camp, north of Spokane. Work has been started on the open-cut on the Bella May claim, preparatory to quarrying the ore. An excellent showing of ore was uncovered. This was stripped far enough to prove it to be continuous, which indicates that practically the whole hillside will do to concentrate. The ore has been tested and is of milling quality. It will be left until the ore-bins are ready to receive it. A 50-ton concentrator will be built to handle the ore.

BRITISH COLUMBIA.

The Rossland mines shipped ore as follows during the week ending April 13: Centre Star, 1,350; Le Roi, 2,135; Le Roi No. 2, 385; White Bear, 35; and White Bear, crushed, 350 tons of ore.——The cylinders are in place for the new hoist at the Centre Star, and the shaft is 70 ft. below the 14th level. Ore is being mined from the glory hole on the Idaho.——At Le Roi, a machine is driving west on the 200-ft. level of the Spitzee. The Great Northern railroad has notified the Canadian Pacific that it will have no more ore for Trail until further notice, as all ore will be sent to Northport. This will necessitate blowing in another furnace at Northport, in addition to the two now running.——The

Map of Part of British Columbia.

concentrator at the White Bear was run for one shift per day, and treated 350 tons of ore, yielding a carload of concentrates.

At the Trail smelter of the Consolidated company, there were received during the week, 4,790 tons of ore. In addition to the ore from Rossland, other mines sent shipments as follows: Snowshoe, Phoenix, 1,017 tons; St. Eugene, Moyie, 668; Eureka, 149; La Plata, Kokanee, 77; Victoria, Nelson, 38; Lone Bachelor, 27; Queen, Ymir, 22 tons of ore.

In the Boundary district, two former producers have resumed shipping, these being the Idaho and the Duncan. The ore shipments for the week ending April 13 were as follows: To Granby smelter, from Granby mines, 17,630 tons; from Emma, 210 tons. To British Columbia Copper Co.'s smelter, from Mother Lode, 2,800; from Morrison, 100; from Snowshoe, 480 tons. To Dominion Copper Co.'s smelter, from Brooklyn, 1,888; from Idaho, 512; from Rawhide, 1,982; from Sunset, 896, from Mt. Rose, 96 tons. To the Trail smelter, from Snowshoe, 800; from Duncan, 20 tons. The total shipments for the week were 27,454 tons of ore. ——The Boundary smelters treated ore this week as follows: Granby smelter, 16,872; B. C. Copper Co.'s smelter, 6,760 tons; Dominion Copper Co.'s smelter, 5,344 tons; the total treatment for the week was 28,976.——W. H. Jeffery has resigned as superintendent of the Crescent mines, and will go to Cobalt.——The Last Chance property at Copper will be worked again.——A diamond-drill is being used in prospecting on the Elkhorn.

Special Correspondence.

Denver, Colorado.

Indictments Against Promoters.—Postal Authorities Take Action.—Metallurgy at Cripple Creek.—Boom Camps and Their Ways.

Much interest has been aroused during the past week by the presenting of indictments by the Federal Grand Jury against several mining promoters. The use of the mail to defraud is an offense punishable under the laws of the United States, and the Federal authorities have gained the reputation of promptly prosecuting all such offenders to the full extent of the law, whenever detected. As a result there is a healthy fear among all such gentry of falling into the clutches of the postoffice authorities, and doubtless many particularly vicious schemes that would otherwise have flourished have been thus prevented. But there are many other enterprises that are less obviously fraudulent in their nature, but are none the less effective in robbing the credulous and confiding. These the Federal authorities can rarely reach, and all such should be curbed by State legislation. Probably the most effective way is to compel all companies to file with some State officer of record a sworn statement of the essential facts of the standing of their companies. The usual promoter's prospectus is composed of glittering generalities and illogical inferences calculated to appeal to the imaginations of the uninformed, while the points upon which any attempt at sound judgment might be based are carefully concealed. Access to the real facts in the case would often serve to enable the intending investor to escape undergoing the double humiliation of the loss of his capital and of confidence in his judgment

It has often been a source of wonder that the metallurgists engaged in treating Cripple Creek ores have shown themselves so little disposed to make use of the experiments of their colleagues upon the telluride ores of Western Australia. The proverb says: "Better late than never," so the late developments in the metallurgy of these ores in Colorado are to be commended. The new 1,000-ton mill of the Golden Cycle Co. embodies some of the features developed by Sutherland and Marriner in Western Australia, and another smaller mill lately put in operation conducts its treatment along similar lines. The waste of experience is the most foolish waste of all. The purpose of metallurgy is to make money out of ore, and neither conservatism, self-pride, nor unwillingness to expend small amounts for the purpose of learning how to save large ones should prevent the manager from trying to make the maximum amount of money from his ore.

The various articles upon mining, especially in the 'boom' camps, that have recently appeared in popular weekly and monthly periodicals have disturbed the complacency of many whose mining interests are legitimate. Articles written by men lacking in technical training and without any previous experience must necessarily be faulty in some slight degree, but in the main the articles referred to have been fair, and not even the promoter can claim that he has been wronged by the too-soon criticism of one who, after a one-day examination of a matter he knows nothing about, writes a scathing denunciation of all he sees. Probably they will serve their purpose, which apparently is to give the general public an approximately correct idea of how business is sometimes carried on in mining camps. The idea of the promoter is that such articles serve to discourage investment in mining properties. But it is at least open to argument whether the investor who brings to mining enterprise nothing beyond a sum of money and a stock of profound ignorance, is a valuable acquisition to any

honest undertaking. And even the promoter can find some solace in knowing that fools are rarely deterred from their folly by having it pointed out to them.

Mexico.

The President's Message.— Prosperity of the Republic.— New Monetary Law.— Meeting of Civil Engineers.— Cyanide Plant at Pachuca.— Car Shortage.— Poor Railroad System.— Scarcity of Labor.—The Torreon Smelter.

The message of President Diaz, read before the Chamber of Deputies at the opening of the second session of the 23rd Congress on the night of April 1, showed in excellent detail the remarkably prosperous conditions of the Mexican Republic. The continued activity in mining was evidenced in the issuance of 2,000 title-deeds during the last six months of 1906. The increase in business of all kinds was shown in the fact that though the new stamp law, which went into effect on November 1, 1906, materially reduced the rate of taxation, nevertheless, the revenue from that source during the last six months of the fiscal year was 400,000 *pesos* in excess of the previous year. The success of the new monetary law seems to be proved in the way in which gold coins, in five and ten *peso* pieces, has been added to the circulation, which on September 16, 1906, amounted to 48,000,000 *pesos*, and has now reached 60,000,000; while of subsidiary silver coins there have been put in circulation 22,000,000 *pesos* (of which 7,000,000 *pesos* are of old pieces re-coined). Interested capital was assured by the President that unruly strikes would be instantly suppressed, and law and order enforced. The President further stated that the delays in the consolidation of the Mexican Central and Mexican National railroads were only such as were natural in affairs of such magnitude, but that it was now only a question of weeks for the working out of the necessary details.

Preparations are now being made by the Mexican Government, the Society of Mexican Engineers, and the members of the American Society of Civil Engineers residing in Mexico (of whom there are 53), for the 39th annual convention of the latter society, which will hold its opening session in the Mineria, Mexico City, on Monday evening, July 8, when the Secretary of Communications and Public Works, Leandro Fernandez, will deliver the address of welcome. The 29th annual convention, held in Quebec in June, 1897, the 32nd in London in July, 1900, and the coming one in Mexico this summer, are the only ones that have been held outside the United States. It is expected this session will be largely attended, and visits are contemplated to the latest interesting engineering works in Mexico, such as the water-works plant for Mexico City, at Xochimilco, the electric power plants at Necaxa and Orizaba, and the railroad and other works on the Isthmus of Tehuantepec.

Perhaps the most interesting event of the present year in mining was the inauguration last month at Pachuca of the pioneer cyanide plant in that district, this taking place at the works of Compañia Beneficiadora de Metales in the Hacienda de San Francisco No. 1, which consists of a 30-stamp mill, with Wilfley tables, special vats for

Map of Mexico.

treating the tailing by agitating with compressed air, and finishing with a system of Butters filters. This, as stated, is the pioneer cyanide plant in that famous old Mexican camp, but it will be closely followed by two similar 180-ton plants, now nearing completion, for the Real del Monte Mining Co., a subsidiary of the United States Smelting, Refining & Mining Company.

The shortage of railroad cars continues to be a serious problem throughout the Republic, and not only has it been the cause of a close approach to a coal famine, as at present in Mexico City, but has been a serious problem among the mines and smelters in getting the ores from the former to the latter. More than once in the last several months the Aguascalientes plant of the American Smelting & Refining Co. has been near to closing down, more because of a shortage of fuel than of ore, due to a lack of cars, for thousands of tons of coal and coke lie at the port of Tampico without means of transportation. And at the Monterey plant of the A. S. & R. Co., only half the furnaces have been in blast for many weeks by reason of the railroads' inability to bring in materials,

both ores and fuel. And other smelters throughout the Republic are running along with scarcely a day's supply of fuel ahead, due to the same cause. With plants along the line of the Mexican Central railroad at least 50% of the difficulties might be obviated if the road-bed were in condition for carrying heavy loads or making fast time. The attempt to do as the business demands has literally strewn the railroad with wrecks, so that it is hoped the Government may soon take charge and make the many necessary improvements. The effect on the mines may be shown by the experience of one mine alone, the Naica Mining Co., in the State of Chihuahua, where it is said something like 200,000 tons of ore were on the dump awaiting shipment, and for several months the company has not been able to get more than three or four cars, when the normal shipment amounts to about 150 cars. When it is taken into consideration that this condition has existed now for some-

Montana.

thing over six months, its seriousness may be imagined. Added to this is the difficulty of obtaining labor, for the wages have so increased throughout the mining districts that now the laborers obtain in a few days the sums for which they formerly had to work a week, and so the great lazy louts, satisfied with that, remain idle the rest of the week, a curse to the country, and a trial to the mining companies and others that need men, until it has almost come to a pass where the Government must step in, and by some kind of a vagrant law force this class of loafers to work for the building up of the country in place of enlisting them in the army, as is done from time to time when the Government needs recruits.

The excellent showing made by the smelting plant of the Torreon Metallurgical Co. has given rise to several rumors to the effect that the A. S. & R. Co. was again after this plant, all of which rumors have been continually denied by Ernesto Madero, president of the Torreon company. It would seem, though, that the Trust must get the plant, for it is the most successful competitor, smelting as it does something over 20,000 tons per month, or 258,552 tons in 1906, an increase of about 10% over 1905, and 25% over 1904. The plant consists of eight lead furnaces and two copper furnaces, and a copper converter is being erected. For the latter and other improvements, the capital stock of the company has just been increased from 3,500,000 to 5,000,000 *pesos*. The last year has shown a profit of 775,285 *pesos*, of which 104,602 *pesos* was expended in improvements, and 420,000 *pesos* (or 12%) paid in dividends. The company has the Cabrillas mine, near Saltillo, under lease, and from there obtains plenty of lead, and from the San Diego mine and mill, at Santa Barbara, Chihuahua, plenty of lead is also obtained. The latter is likewise a heavy zinc producer. Custom ores containing lead and copper, as well as the necessary silicious ores, come to this smelter from all over the Republic, successfully competing with the Trust at many points.

Butte, Montana.

Decreased Output of Copper.—Mining News From Butte.—Another Deep Shaft.—Silver Mine Near Dillon.—Dividends From the Coeur d'Alene.

The production of copper for April will probably not exceed 28,000,000 lb., and it may be even less. The total production from Butte for the first four months of the year will be between 15,000,000 and 18,000,000 lb. less than that of the same period in 1906. Many causes contributed to the decrease, including labor troubles, severe winter weather, fuel shortage, and lack of transportation facilities. A gradual reduction in the percentage of copper in the ore mined by the Amalgamated companies makes unlikely a material increase in the output of copper during the remainder of the year.

The Trenton Co. has about completed a station at the 2,100-ft. level of the Gagnon mine and will shortly begin cross-cutting to the vein at that depth.——The North Butte Copper Co. is carrying on a lot of development work in the Berlin, Edith May, and Miners Union claims. On the Speculator vein the company has sunk a winze from the 1,600-ft. level and from the winze drifts have been run on the vein, opening good bodies of ore assaying six per cent copper.——The Butte Coalition Co. is mining about 1,500 tons of ore per day, and is pushing development work in the Rarus, Corra, Minnie Healey, Tramway, and Alice mines. Ore is coming from the Rarus, Minnie Healey, Corra, and Nipper, and some from the Pennsylvania.——The Butte-Montana Co. is cutting a station at the 900-ft. level of the Alex Scott mine. The shaft is to be put down 1,200 or 1,500 ft. On the 600-ft. level the company has some fine ore, carrying copper glance. Some of it is being shipped.

New York and London men have been brought together in a syndicate to develop a group of claims, 11 in number, situated just south of the properties of the Butte & Bacorn Mining Co. It is expected that exploration work will begin about the first of May. Before the syndicate took hold of the enterprise the ground was thoroughly examined by an English engineer who made a favorable report on it. He will be in charge of the work. The plans are to equip the property with electrical machinery and to sink a four-compartment shaft at least 1,500 ft., which will take more than two years. Sixty feet per month for a four-compartment shaft is considered good progress. The men interested in the enterprise will put up the money for the work until a sufficient showing has been made to warrant the organization of a company, a proceeding that has the merit of novelty, as the usual method is to organize a company, sell stock, and then let somebody else look for a showing in the ground.

The Butte-Milwaukee Copper Mining Co. has sunk its new shaft on the Colonel Sellers to a depth of 215 ft., and expects to make more rapid progress hereafter, as it is now better equipped for work. The shaft is in solid rock, it being the intention of the company to keep away from the vein in order to insure a good working shaft.

The Pittsburgh & Montana Mining Co. has opened a fine body of copper glance in a winze from the 1,400-ft. level, and drifts are being extended. The company is shipping five cars of ore daily, equal to more than 200 tons. The physical condition of the property has been greatly improved under the management of Oscar Rohn,

and miners employed in the Pittsmont mines report that the company will soon be able to increase its output.

Some excellent smelter returns on ore from the mine of the New Departure Mining Co., 12 miles from Dillon, have been received. A recent shipment of 25 tons to the Washoe works contained 15 tons of first-class and 10 tons of second-class ore, the latter yielding 337 oz. silver, $1 in gold per ton, and 2.2% copper; the second-class giving 65 oz. silver, $7.20 in gold, and no copper. W. B. Orem, deputy State Mining Inspector, says the New Departure is really a wonderful property. In a raise being made from the 250-ft. level a body of ore has been encountered, some of which assays 1,008 oz. in silver. A fair sample of the ore in the shaft, says Mr. Orem, will assay 150 oz. per ton. While the company is doing a lot of development work from the old shaft, a new shaft is being sunk and is now down about 35 ft. In the new shaft a vein o ore has been cut that is three feet wide and assaying 310 oz. silver per ton. Several months ago the bond was takeu up and the title now rests in the company, free of incumbrance. There is about $15,000 in the treasury and there are about 2,500 tons of ore on the dump that will run from 40 to 60 oz. silver. The property is well equipped for development as well as mining, the company having two 40-h.p. boilers, an 8½ by 10 in. hoisting engine, a six-drill compressor, and pumps of sufficient capacity to handle a large amount of water. Jesse Davis is in charge of mining operations and 10 men are employed.

Basing the estimates on dividends paid during the first three months of the year, the Cœur d'Alene will pay about $7,000,000 in dividends in 1907. Seven companies have disbursed $1,547,500 in three months, as follows: Federal Mining & Smelting Co., $510,000; Bunker Hill & Sullivan, $540,000; Hercules, $228,000; Snowstorm, $140,000; Hecla, $100,000; Success, $20,000; Monitor, $9,500; total, $1,547,500. The Snowstorm and Monitor are copper mines; the Success produces zinc and lead; the others are silver-lead producers. The Black Cloud-California Co., operated by Pittsburgh men, is said to have earned $40,000 in March. It is predicted that among the early additional producers will be the Stewart, Alameda, and Charles Dickens. The Stewart, owned by F. A. Heinze, has a large amount of ore on the dump.

Cripple Creek, Colorado.

Successful Leases.—Several Strikes of Ore.—Mining on School Lands.—The Isabella Co.—British-American Dividend.—General Activity.

A clean-up has recently been made after a run of three weeks at the smaller of the two Homestake mills on Ironclad hill. The Ironclad Milling Co. has a lease on this plant and is treating ore averaging $3 per ton obtained from the adjacent property. The gold was shipped to the U. S. mint in Denver and was estimated to be worth $5,000.——F. R. Marsh and John Hodges have sold their lease on the Callie to A. E. Humphries and associates, the present operators of the famous Little Clara, which the Callie adjoins. The consideration is said to be in the neighborhood of $10,000, and includes the two ore-houses at the mouth of the Ophelia tunnel and the tramway from the latter to the F. & C. C. tracks.——Good ore is being mined from a block of the Cameron school section on Bull hill operated by the School Section Leasing Co. About four cars per week are shipped giving returns around $30 per ton. The royalties are paid to the school funds of the Cripple Creek district.

The Henry Adney Mining Co. has purchased a 10-drill compressor from the Chicago Pneumatic Tool Co. The machine has arrived in the district and will shortly be in operation on the property. It is of the Franklin type and will be driven electrically. The management is also contemplating the installation of skips, which will materially add to the output of the mine. Ore is being broken on the 500 and 600-ft. levels from a 3-ft. vein and gives returns of several ounces per ton.——A strike of ore is reported on the Twin Sisters claim, which is being operated by J. E. Smith. The ore was encountered at a depth of 80 ft. and enough has been broken for a shipment, the returns from which should be better than an ounce.——It is stated that the Golden Cycle Mining & Milling Co. is about to start its fourth roaster, having a capacity of 100 tons per day. This will make the daily capacity of the mill 400 tons. The Golden Cycle mine is closed temporarily pending the installation of two 2½-ton skips in the main shaft, the former system of hoisting by means of a cage having been found inadequate to handle the output.

At a meeting of the British American Mining Co. Ltd. on the 12th inst. a dividend amounting to $4,000 was declared. This is a close corporation operating the South Dante on Bull hill. The foregoing amount brings the total profits, divided between the partners, to $12,000. The sinking of the new shaft to connect with the workings above the Trail tunnel is progressing rapidly, the shaft now being down 25 ft. Good-looking veinstuff has been encountered in the sinking, but not of sufficient value to be worth saving.——A circular letter has been issued by the Isabella Mines Co. to its stockholders offering 30,000 shares of treasury stock at 25 cents per share for the purpose of liquidating the debts of the company incurred by erecting the cyanide plant, improving the property, and in the payment of $13,000, the judgment in the Glenn case. The annual report of the manager, G. D. Kilborn, is attached. Up to about one year ago the property was worked entirely by lessees. The company itself then started operations, only a few small blocks of ground in the main workings being leased. The output was comparatively large, but the value was low compared with the average grade of the district. As an outcome of this the company last August began building a cyanide plant of a capacity of 150 tons per day to treat this low-grade ore.

The Union Leasing Co. operating on the South Clara D. of the Lexington property is stated to have entered into negotiations with the management of the Portland mill at Colorado City for the treatment of about 50 tons of its ore per day. There are large quantities of ore that will run in the neighborhood of $10 per ton in the lower levels of the mine, the width of the orebody ranging from 15 to 20 ft. A trial shipment to the mill has given satisfactory results. The above leasing company also operates the Mabel M. on Beacon hill, and has resumed work on that property after a shutdown of several days, while a new boiler was installed and various repairs made. At the 300-ft. level of the new shaft at the north end of the claim a good orebody has been opened up, which gives returns of over an ounce.——Good ore is being obtained by A. J. Beckman & Co. on the Lottie claim, block 231 of the Stratton estate on Bull hill. Operations are being carried on only a few feet below the surface and samples from the vein assay several ounces per ton. Sinking is now going on, but a drift will shortly be driven on the vein in a northerly direction to cut a dike, when it is hoped some pay-ore will be encountered.

A strike has been made during the last few days in the Pharmacist mine, situated on Bull hill. The cross-cut being driven in an easterly direction from the shaft has cut a good-looking vein. Samples taken over a width of 3 ft. assay 5 to 6 oz. in gold per ton. The property is at

present under lease to Edsall, Key & Co. of Colorado Springs.——While driving on the 600-ft. level of the Chicken Hawk of the Katinka Mining Co. on Guyot hill, a strong veing has been encountered 300 ft. south of the shaft. The vein is over 6 ft. wide and is believed to be a continuation of the famous C. K. & N. vein, which should cut the Chicken Hawk claim.

Salt Lake, Utah.

Utah Apex Mine.—Transfer at Bingham.—Shipments From Tintic.—Output of Park City.—Railroad Building.—Consolidating Properties.

Late developments in the Utah Apex mine are of a character to give that property a position ranking among the leading copper mines of Bingham. About 100 tons of high-grade ore is being shipped daily. The completion of the Markham Gulch mill within the next few weeks will provide facilities for the treatment of the low-grade ores of the property. The Parvenue adit, which is to be the main exit for ores in the future, has been driven over 2,300 ft.——An Eastern syndicate has closed a deal for the purchase of a control of the Bingham Amalgamated Copper Co., owner of the Copper Glance and Illinois mines, at Bingham, on a basis of $750,000. Payments on the purchase price are to extend over a period of twelve months.

The ore shipments from the Tintic mining district last week amounted to 136 carloads, the shipping mines and respective amounts being: Ajax, 3; Beck Tunnel, 9; Black Jack, 1; Bullion Beck, 4; Carisa, 8; Centennial Eureka, 56; Colorado, 1; Eureka Hill, 3; Gemini, 6; Godiva, 2; Grand Central, 6; Laclede, 1; Lower Mammoth, 6; Mammoth, 10; Scranton, 6; Swansea, 2; Tintic Iron, 6; Uncle Sam, 2; Yankee Con., 4 carloads.—— A merger of the Uncle Sam Con. and May Day mines in the Tintic district has been practically assured. The deal is progressing favorably, and inasmuch as both mines are under the same management there seems no doubt but that it will be completed.—— The Western Pacific tracklayers, who are near the Nevada boundary with steel, have been crossing a large deposit of salt in western Utah. The surface is as hard as a pavement on a city street, and the ties are put down on it, to be followed with gravel ballast.

Ore shipments from Park City last week amounted to 1,780 tons, the leading shippers and respective amounts being: Daly Judge, 752; Silver King, 332; Daly West, 632; Ontario, 114 tons. Nothing of an official character has been released as yet relative to the merger of the Silver King, Keith-Kearns, and other mines at Park City. However, some of the principals in the transaction have been in conference in New York. There appears to be not the slightest doubt about F. Augustus Heinze being interested in the transaction.

Ore is being moved over the tracks of the Rio Grande Western railroad to the bins of the new mill of the Utah Copper Co., at Garfield, and May 10 is set as the date for the starting of the first unit of the plant. In the meantime the work of constructing the second unit is progressing steadily.—— At a meeting of shareholders of the Morrison Mining Co., in Salt Lake, the name of the corporation was changed to that of the Imlay Copper Co. The capital stock of the company was also increased from 300,000 to 400,000 shares. S. M. Bamberger, of Salt Lake, is manager.

Graders are pushing work rapidly on the new branch line of the Salt Lake route from Caliente to Pioche, Nevada. The track-layers will follow the graders closely. —— The Moscow Extension Mining Co. has been formed to operate the Russell group of claims in the Star district, Beaver county. Preparations are being made to resume production at the Burning Moscow mine in the same county. A permanent working shaft is being sunk; this is now down 235 ft., and will be continued to 300 ft. The Frisco Contact Mining Co. expects to encounter shipping ore soon in the drift being run toward the contact on the 500-ft. level.—— The mill at the property of the Jennie Mining Co., at Gold Springs, Iron county, is said to be a complete success, and is handling an average of 30 tons of ore daily. C. A. Short is manager.—— The head offices of the Nevada Hills Mining Co., operating at Fairview, were ordered moved to Salt Lake at the recent meeting of shareholders held at Goldfield, Nevada.

London.

Rio Tinto.—A Splendid Record.—Tremendous Operations.—Zinc Corporation Changes.—The Rival Processes.—Cornish Mining.—Public Interest Not Maintained.

The last annual report of Rio Tinto is a fine record of continued prosperity on a magnificent scale. At the thirty-fourth ordinary general meeting of this Company, held this week, the chairman said the net profits for 1906 amounted to £2,171,267, which enabled the directors to declare a final dividend for the year of £3 per share, making, with the interim dividend, 11½% for the year. Increased profits have come from the higher price of copper, and also a good additional profit from a larger quantity of ore sold for its sulphur contents. Economies have partially neutralized the increased expenditure of nearly £100,000, caused by the rise in Spanish exchange, but Spanish, French, and English taxes again increased, and were £300,000 higher, joined with a further drop in securities, chiefly Consols. The large screening plants have done well in the past year, the railway and pier handling practically half a million tons of sulphur ore, in addition to the cupreous ore hitherto carried. The water supply at the mines, owing to dry seasons, has been giving trouble, and reduced water consumption may mean a reduced output of copper, although one summer's scarcity of water merely postpones profits for a few

Eastern Australia.

months. The chairman added that industrial enterprise was active in all countries; copper was, therefore, in great demand, and all new machinery and ships needed copper in a greater or less degree. It was rapidly becoming realized that it is more economical to create power at centres in large units, and distribute by electric current, than the use of numerous small steam-engines working locally. This had, even in heavy railway work, gone beyond the experimental stage. Probably, therefore, the electrical age had hardly commenced; and even if new sources of supply were found, their copper would continue to fetch remunerative prices.

The past year was by far the most prosperous in the history of Rio Tinto, which dates from 1873, although the first dividend was paid for 1879. In the following table are shown the profit earned and its distribution in the past three years:

	1904	1905	1906
	£.	£.	£.
Profit on produce	1,667,530	1,845,291	2,414,582
Interest on investments	22,196	20,973	20,979
Railway receipts	18,945	25,748	29,857
Rents, &c	5,836	8,527	10,176
Gross profits	1,714,507	1,800,539	2,478,594
Brought forward	20,189	27,480	26,953
	1,734,696	1,928,019	2,505,547
Administration	77,791	83,486	98,414
Income tax &c	163,933	130,075	168,974
Debenture and other interest	198,661	159,429	.....
Written off	49,559	47,889	61,892
To reserve, &c	2,500	3,000	5,000
Preferred dividend (5%)	77,272	77,187	77,187
Ordinary dividends	1,137,500	1,400,000	2,062,500
Rate per annum	70%	80%	110%
Carried forward	27,480	26,953	31,580
Copper produced, tons	33,478	32,280	34,098
Average price	£59 0 5	£69 12 0	£87 9 3

Since the Company commenced to pay dividends, in 1879, the total distributions, with those to be shortly made, will have exceeded £18,365,000, while the undertaking has a present market valuation of close upon £40,000,000. For each of the three years ended with 1904 about £200,000 had to be set aside for debenture interest and redemption and general interest; but in the early months of last year 4% first mortgage bonds, amounting to £2,989,740, were paid off, so that for the past year there is no payment for interest. The requisite funds for the extinction of the debentures were provided for by the issue of 50,000 Ordinary Shares of £5 each at the price of £63 each, providing £3,150,000, reduced to £3,103,158 by the expenses of issue and the Spanish tax on the extinction of bonds. In other words, with a nominal increase of £250,000 in the share capital the Company's liabilities have been reduced by £2,989,740, and this sum being brought into the accounts has made it possible to write down very considerably the amount at which the mines and inert assets in Spain stood on the property and assets side of the balance-sheet. In the course of the past twelve months the total amount of pyrites handled at the mines was 1,923,716 tons of an average copper content of 2.411%, as against 1,830,104 tons with an average of 2.363% in the preceding year, while the copper produced during the year by treatment at the mines was 21,827 tons, in contrast with 19,530 tons, and the amount of fine copper in the pyrites shipped brought up the total output to 34,098 tons, comparing with 32,280 tons in 1905. The deliveries of sulphur ore, which had been 157,850 tons in 1904 and 308,184 tons in 1905, rose last year to 477,843 tons.

The following important cable is announced from the Zinc Corporation's Melbourne office: "After thorough examination and trial of A. Queneau's system of treatment, we have come to the conclusion that it is not commercial success; however, we have altered one unit to Cattermole process, and have proved success of Cattermole process system of treatment. We are obtaining good extraction lead and zinc from all materials, including slime, and are producing and shipping concentrate of good grade. We have abandoned A. Queneau's system of treatment, and are altering balance of No. 2 plant to Cattermole process. We should be running full time, 500 tons per day, in about a month. In the meantime running one unit on Cattermole process, treating 140 tons per day." In the opinion of the *Mining World*, it is doubtful whether the decision in the Supreme Court of Victoria in favor of the Broken Hill Proprietary Co., against which the Potter Process Co. had brought an action for alleged infringement of patent rights, will be allowed to pass unchallenged. The issues at stake are too great to admit of the matter remaining where it is, a verdict in favor of the plaintiff involving the payment of royalty on the vast quantities of zinkiferous tailing owned by the Company. The Potter salt-cake process for the extraction of zinc from the Broken Hill sulphide tailing is the property of a company having a capital of £250,000. The royalty charged for treatment is 2s. 6d. per ton, which, if paid by the Proprietary Co. on its accumulated tailing would approach something like £750,000. The Delprat process, adopted by the Proprietary Co., resembles the Potter in several respects, but not sufficiently, according to the Supreme Court judgment, to constitute an infringement of the Potter patent. In the Potter salt-cake process the tailing is poured into vats of peculiar shape and construction, and containing a prepared solution of sulphuric acid, diluted to 1%, the result being that the metallic particles are attacked by air globules, to which they become attached and float to the surface, where they are collected. There are several other processes worked at Broken Hill, including one in which the zinc particles are electrically attracted from the gangue, and another in which the valuable constituents are absorbed by a master absorbent and subsequently separated; also the Bavay process, in which the metallic particles are aerated and floated off. Thus there is apparently a general resemblance in the various processes, but improvements are so frequently made that a more perfect and cheaper method may yet be devised.

Cornish mining requires a stimulus of some sort just now to prevent the waning of public interest, which, it must be admitted, has scarcely come up to expectations. At the same time a certain amount of attention is being given to the resuscitation of old mines, which should result in a show of some kind before long. It is rumored that Great South Tolgus, West Tolgus, and Wheal Eddy are to be worked by a single company, and that arrangements are now being made for the opening of these three mines. Wheal Eddy is situated at Tolskithy, and Great South Tolgus and West Tolgus are to the east of it. The main Wheal Agar lode, it is said, runs through Wheal Eddy sett. These mines were originally worked for copper, and sixty years ago Great South Tolgus £10 shares were worth £140 each. Any of the ancients who still survive those times are doubtless prepared to inform newcomers that in each of the properties mentioned "a fine lode was left in the bottom." Operations are reported as being carried out with great energy at the Tywarnhaile mine. The mill and concentrator has been running constantly for several weeks, and the first lot of copper concentrates from the old dumps ('burrows') is now being carted to Portreath for shipment to Swansea. The concentrator continues to do excellent work, and the ratio of concentration is at least 20 to 1. Both the mill, concentrator, and pump supplying the water for the mill are motor-driven. Within about a month the mill ought to be running steadily on ore taken from the mine.

Cobalt, Ontario.

Prospecting in Northern Ontario.—How Claims Are Obtained.—A Prospector's Paradise.—Chances of Discovery.—Recent Finds.

The phenomenal results attained by development in the vicinity of Cobalt, where practically within two years 18 properties have been put on a shipping basis and 16 others are ready to ship, has led to the prospecting of an extensive area in northern Ontario hitherto not even known by name except perhaps to war veterans who have had their claims or lots allotted to them in this unsettled region. These lots, or 160-acre claims, are exempt from location, but otherwise this vast territory is open for location and development.

Cobalt having been found by a chance discovery, is it not reasonable to suppose that many other districts may be discovered by systematic prospecting? This argument is the great theme at Cobalt and is the chief incentive for prospecting this unknown region. No doubt many valuable discoveries will be made and many good mines developed, for the whole country about here is well mineralized and contains most of the useful metals.

In Cobalt, mines and mining engineers are made over night. A chance discovery of a blind vein will convert a prospect into a shipping mine, and the management of one of the many properties in the vicinity will convert a farmer into a mining engineer.

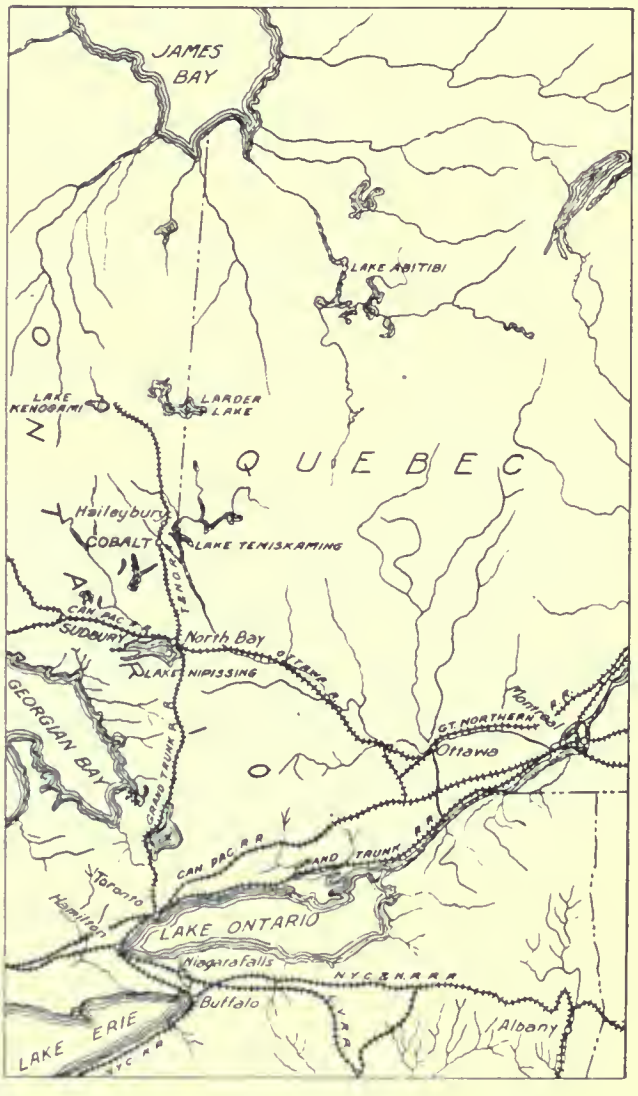
Most of the shipping mines being in Coleman township, the 1,500 or more claims outside of those already proved to contain shipping ore, are valuable according to position in respect to such claims, to whether they have been simply recorded, passed, or patented. A staked and recorded claim is a claim (20 acres in the surveyed portion of Coleman township, or 40 acres in any other locality) that has been properly staked, with a discovery of mineral in place, that has been sworn to and recorded at the Recorder's office. A 'passed' claim is one on which the conditions have been fulfilled and the discovery passed by the Mining Inspector, although this does not signify that the mineral discovered is of any commercial value, it means only that the Inspector is satisfied of a discovery of valuable mineral in place.

A claim with a 'working permit' means that after the claim is recorded a permit is applied for and granted, which gives the licensee the exclusive right to prospect for mineral, and the licensee shall perform mining operations thereon for at least five days in each week during the six months next following two weeks after the issuance of such working permit, or an equal amount of work in less time, the time from the fifteenth of November to the fifteenth of April excluded. A 'patented' mining claim means a claim on which all the conditions required by law has been performed and a patent granted by the Government, whereby the patentee has exclusive right to all mines and minerals thereon, but no lands shall be patented for mining purposes in any forest reserve. No licensee may record more than three mining claims in any one year.

Recorded claims in Coleman on which nothing has been found can be bought for $350. This same claim with a working permit will sell for $1,000; if passed by the Inspector, it will fetch $10,000, so that with good luck there is money to be made prospecting claims for a good discovery that can be sold. The amount of work required is a matter of chance, for the ground being, as a rule, covered with 4 to 16 ft. of sand and gravel, it must be blindly trenched, and any streak of calcite followed, along its strike or downward, until the showing is sufficient to pass inspection. This may cost from a few dollars to many thousands. It may naturally be asked whether any claim with no showing at all on the surface has turned out to be of value. The answer to this is decidedly in the affirmative; in fact, many claims that have shown nothing of value in the trenches have developed rich ore on sinking.

This region is the prospector's paradise. He is almost certain to be rewarded, at least, for his time. The country is easy of access, food comparatively cheap, and walking good; that is to say, the country is mostly level or rolling, with no high ranges of mountains or deserts to cross. The winters are severe but easily endured, the summers short, hot, and bothersome with flies and mosquitos.

Staked claims to the east of Cobalt, near rich discoveries, sell for $10,000 to $50,000, and if passed they bring as much as $5,000, although no ore of a sufficient value to ship has been discovered. Valuable discoveries of silver-bearing calcite have been discovered outside of Coleman; in Bucke, where at least one mine is shipping rich ore and others are ready to ship; in Casey, Harris, James, and many others within a radius of 50 miles of Cobalt. The Montreal River district and other townships north of Cobalt have not had the advantage of summer prospecting, most of the work having been done this winter with four feet of snow and the thermometer many degrees below zero, so just what this year will bring forth is uncertain. Gold is being discovered from Larder lake north into Abitibi, 50 to 100 miles north of Cobalt, but little work has yet been done to prove the extent or value of the discoveries. No doubt some good mines will be developed with a horde of wild-cats close on the trail.



Map Showing Position of Cobalt and New Districts in Ontario.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

DUTCH GUIANA produced 28,272 oz. of gold in 1905 and 31,332 oz. in 1906.

IN the early days of tunneling, machine drills were mounted on cars running on tracks, and this is still the practice in some parts of Europe.

BY subjection to the action of carbon dioxide and water, orthoclase may alter to muscovite or kaolin, which action is accompanied by the production of potassium carbonate and silica.

THE most famous South African diamond mines are at Kimberley, De Beers, Dutoitspan, Bulfontein, and Wesselton. These are in a circle about three and one-half miles in diameter.

SEDIMENTARY CLAYS can be distinguished from residual clays chiefly by their stratification, and also by the fact that they commonly bear no direct relation to the underlying rock on which they rest.

WITH the hydrates of sodium and potassium in great excess, salts of cobalt give a liquid of a very intense blue color, especially when heated. This blue liquid is an alkaline solution of cobaltous anhydroxide.

THE gold deposits of the southern Appalachian States are of pre-Cambrian age; so also is the schist in which the Homestake lode occurs. The copper deposits of Grand Encampment exist in rocks of similar age.

THE amount of water used on vanners, varies in different mills, from three to eight gallons per minute per vanner. This includes the water fed with the pulp and the cleaning jets above and below. Clayey, talcose, slaty, and calcareous ores require more water than quartz ores.

CONCRETE is a troublesome material in which to drill deep holes; it is a good plan to use water under pressure, with a wide flare bit, permitting a small copper waterpipe to be inserted nearly to the bottom of the hole, so that chips and dust are carried off before they can wedge the bit.

THE most persistent beds of marine clays, which are sedimentary clays deposited on the ocean bottom, where the water is quiet, occur in the rocks of the Silurian, Devonian, and Carboniferous systems, but beds of considerable horizontal extent are found in the Mesozoic formations.

THE best thickness of bed on the ordinary side-shake vanner is about one-fifth of an inch, measured over the small rollers, and should probably never exceed one-quarter of an inch, although the thickness of the bed should be made dependent upon the size of the individual grains being treated.

IN the Tintic silver-lead-copper mining district, the most common form of chemical alteration is the substitution of silica for lime, which, when complete, forms jasperoid. The jasperoid is often intimately associated with the ore, and also forms large bodies which contain little or no valuable mineral.

AMONG the more recent applications of fluorspar to new uses are: In the reduction of aluminum from bauxite; as a flux for gold ores; as a bonding constituent for emery wheels; for carbon electrodes, increasing their lighting efficiency and at the same time decreasing the amount of required current.

DETONATORS for exploding dynamite consist ordinarily of a mixture of mercury fulminate, and potassium nitrate or chlorate, placed in a copper capsule; when the cap is to be fired with a fuse, the fulminate is covered with shellac, collodion, thin copper foil, or paper, and the end of the capsule is left open to receive the end of the fuse.

SERICITE-SCHISTS are mica-schists whose mica is sericite. Mica-schists embrace a wide series, ranging from rather coarsely crystalline varieties to others that are very fine-grained and are almost slates. If the latter, when the mica is in aggregates of a silvery white color but of the composition of normal muscovite, the mineral is called sericite, and the rock a sericite-schist.

AT Butte, Montana, occur two granites of different ages, one of which is about 10% more silicious than the other. The less silicious granite contains hornblende and biotite, while the other contains but little. The fractures along which the ore-bearing solutions passed cut both these granites, but the veins are rich in copper in the less silicious granite, while in the more silicious rock the veins are equally wide and strong, but are lean, and composed chiefly of quartz, with comparatively little pyrite and copper.

FILTRATION as usually carried out, is the separating of an insoluble substance from the liquid in which it is suspended. This can be done by means of a porous medium, or filter, of such material as not to be attacked by the substance to be filtered, and which is sufficiently porous to allow the liquid to pass through it, while coarse enough to retain all solid matter. Many different filtering mediums have been used, such as linen, woolen, and cotton fabrics, felt cloths, straw, raw cotton, coarse and fine sand, burnt clay, animal and vegetable charcoal, soft leather, unsized paper, crushed glass, sand, asbestos, and platinum sponge.

A PIECE OF METAL is not a homogeneous single thing. It is a collection of grains or granules that built it up just as granules built up a glacier. The grains of metal are irregular in shape and unequal in size. Their existence is revealed by polishing and etching the surface of the metal and examining it under a microscope, when the grains can be readily distinguished by differences of texture and the boundaries between them can be clearly traced. Investigation shows that each grain is, in fact, a separate crystal, and the irregular boundaries are due to casual inequalities in the rates at which the various crystals have grown during their formation.

MANY sedimentary clays, especially those of marine origin, after their formation, are covered up by many hundred feet of other sediments, due to continued deposition of a sinking ocean bottom. It will be easily understood that the great weight of this overlying sediment will tend to consolidate the clay, by pressure, converting it into a firm, rock-like mass, termed a shale. That the cohesion of the particles is due mostly to pressure alone is evidenced by the fact that grinding the shale and mixing it with water will develop as much plasticity as is found in many surface clays. An additional hardening has, however, taken place in many shales, due to the deposition of minerals around the grains, as a result of which they become more firmly bound together.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Gold Dredging.

The Editor:

Sir—In your issue of November 3, 1906, Mr. D'Arcy Weatherbe discusses gold dredging, with special reference to Mr. Curle's letter on the same subject in the issue of January 27, 1906. In the closing portion of Mr. Weatherbe's letter, he refers to a letter of mine of July 28, relating to the same subject, and advances some criticisms thereon.

While in no way wishing to decry the valuable contributions of Mr. Weatherbe concerning California dredging, I must admit that I fail to see much force in the last portion of his letter. I have not seen, as yet, from Mr. Weatherbe or others, a specific answer to my question in the issue of July 28, as to the cost of dredging. For the present I leave this point open.

Mr. Weatherbe objects to the "generalization" that flood-plains are the proper field for gold dredging. He answers my statement by an unsupported generalization of his own that "Neither the territory on the Yuba where the river bottom, with its accumulation of tailing overburden, forms the gold-bearing material, nor the bench gravels of the American river at Folsom, together forming probably half (in value) of the available fields, come under this head."

I hope to support, in the following, the view that both the areas referred to are typical examples of "flood-plains reduced nearly to base-level." Before proceeding, I wish to make the comment that notwithstanding the number of highly-trained men now engaged in the examination of dredging conditions, and in the prosecution of the dredging industry, geological factors have not been taken sufficiently into account in selecting the ground. I crave space to insert here once more a description of what I believe to be the essential conditions for a dredgeable territory.

"Taking the country about Oroville, California, as the best example in the United States, let the geological conditions be considered. To the north and east the erosion of a vast extent of mining country, whose rocks are penetrated by gold-bearing veins, has contributed little by little through geological ages to the mass of detritus now occupying the bed of the Feather river. The wearing down of mountains (originally very much higher than at present) through a vast amount of time, has caused the formation of a valley of extraordinary width, but of no great depth. The massing of stream detritus is also responsible for a decrease in the gradient and a slowing down almost to a topographical equilibrium of the formerly swift current of the river. The stream, unable under the conditions to cut its way by virtue of the material which is carried in suspension, has for a long time been depositing its load, filling its wide valley with sand and gravel, together with the less destructible of the metallic particles, and notably gold. Geologically speaking, the rate of deposition of the river's material may be said to be on the increase and the current of the river, still of considerable velocity, to be greatly lessening in swiftness. Later in its geological cycle the Feather river will doubtless assume, on a smaller scale, the present character of the Mississippi, forming ox-bow curves, cut-offs, and as it were, losing its way among constantly shifting sand-bars. The accompanying residual gold, as it travels to a greater and greater distance from its original source in the veins of the mountains, becomes more and more finely divided, even to microscopic dimensions, and increases in purity, and the degree of evenness with which the particles are distributed in the gravel becomes a phenomenon of constantly increasing definiteness and importance.

The Country Around Oroville, California.

Such a set of conditions as that obtaining on Feather river is the exception rather than the rule in the western part of the United States, and even in California. The above explanation has been entered into in order to present in some measure the reason why, on the California river referred to, the conditions are not only favorable but eminently suited to gold dredging. It is hardly necessary to state that the amount of gold increases in geometrical ratio the lower it lies in a given bed of gravel. Thus old rather than young valleys are favorable for dredging.

Additional reasons of great weight why geologically old valleys should be looked for are that the size of boulders is greatly decreased, gravel becomes by long abrasion uniform in size, the angularity of the fragments disappears, and a bed of pebbles, round and easily handled, is the

result. The even distribution of the gold which, as mentioned above, is an invariable accompaniment of old and wide valleys, is a point in favor of this sort of mining, looked at from the standpoint of a business enterprise. At the same time it is evident that the finely divided state in which such gold is found necessitates the highest skill in recovering it."*

The above description was written before the Yuba and American river areas had become prominent for dredging. These areas are not different in geological history from the Feather river dredging area. In fact, I believe they would be classified by any geologist as part of the same general base-level. The Yuba river, 12 to 16 miles east of Marysville, has a gradient of less than 50 ft. per mile. It flows in extensive gravel and silt-filled plain. The fact that 25 ft. of tailing from former operations covers the plain in and near the river-bed is an incident of artificial origin, which has accentuated the natural base-level conditions previously imposed. Mr. Weatherbe perhaps means that the gold exists in the bottom of the Yuba river by virtue of the tailing that covers the gravel deposited in the natural way. If this be the case, I admit that a special condition exists, but as it has no bearing on the geological conditions, it does not constitute a refutation of my contention. On the other hand, my understanding has always been that the Yuba gold occurs mostly in the undisturbed gravel beneath the tailing. If this be true, it is as surely the gold of a flood-plain as is that of the Feather river.

The deposition of fine alluvial gold in great river valleys by floods and periodic innundations may be called flood-gold. No one can say in what portions of a given broad valley the local currents will deposit such fine gold. The result must be that the flood-gold occurs in patches distributed irregularly over a wide area. On the Yuba I believe it is a coincidence that one such patch, determined by prospecting, lies in the area crossed by the present river-channel. Similar patches will be found over a greater area than that at present exploited.

As regards depth, wells at Wheatland on the Bear river, a part of the same great base-level, went through 150 ft. of gravel, clay, hard-pan, sand, and a further 300 ft. of greenish sand, all of Tertiary or late Cretaceous age, and it is fair to assume the same depth in the Yuba. Gold may exist throughout this depth in various layers. By any present method it is unrecoverable.

Messrs. Becker, Lindgren, and Turner, in the Smartsville folio of the Geologic Atlas, July, 1895, state, regarding the Yuba valley: "The present system of watercourses is steadily degrading the older formations and depositing the sediment on flood-plains forming bottomlands of greater or smaller extent or alluvium." The elevation that occurred in Pleistocene time and which affected the American river area thirty vertical feet or more, may have had some influence along the Yuba, and even the very moderate grade of stream was probably less than at present. The river is at present doing but little cutting, except in the way of removing its artificial load. The present dredge-tailing is rapidly removed and re-deposited further down the stream, when the current of the river comes in contact with it. I witnessed an impressive illustration of this cutting away during a season of high water on the Yuba, in October, 1904. As far as the Yuba valley is concerned, I think it would be difficult to find a fairer example of a flood-plained stream reduced nearly to base-level.

The area of bench-gravel now being dredged adjacent to the American river at Folsom offers the conditions of an ancient base-level raised slightly over 30 ft. above the present level of the stream that is reducing it. The elevation af Folsom does not exceed 140 ft. above the sea, and the gradient of the American river is less than 25 ft. per mile. The fact that the auriferous patch of gravel, which is being dredged, lies in a low bench, means in this case that the cycle of base-leveling has been completed, and that the terrane has undergone a slight elevation, and is again being disintegrated. It has not only been reduced to base-level, but has, as it were, been lifted up for exhibition, to show what a base-leveled flood-plain should look like.

Mr. Weatherbe has shown us that he knows a great deal about dredging operations in California. He will, I am sure, pardon this protest from a geologist who has endeavored to apply scientific principles to the search for dredging territory, and he will recognize that there may be ways of determining what ground presents dredging possibilities, undreamt of in his philosophy.

C. W. PURINGTON.

London, March 11.

*"The Gold-Dredging Fields of Eastern Russia," by C. W. Purington and J. B. Landfield, *Engineering Magazine*, 1901, p. 398.

The Salton Sea.

The Editor:

Sir—In your issue of March 30, Wm. R. Bailey ridicules the idea that the Salton Sea can in any way influence the rainfall or the climate of Nevada and of the territory east from there. He speaks of the evaporation from the Gulf of Mexico and from the Gulf of California, and asks why the country in the neighborhood of the Gulf of California has not been flooded. His reasoning seems to be that the nearer to a large body of water the greater the rainfall. At Cape St. Lucas, on the extreme end of Lower California, the rainfall is almost nil, yet Cape St. Lucas is next to the Pacific Ocean and to the Gulf of California.

The heavy rainfalls throughout the world occur in the mountains and not on the coast. The factor of evaporation is secondary to, and of minor importance compared with, the conditions favorable to precipitation. The air may be humid, but until something happens to cause the vapor to condense there will be no rainfall. The clouds from the Pacific Ocean are wrung dry in their drag east across the Sierra Nevada, so that by the time they are over the great plateau between the Rocky Mountains and the Sierras they have but little available moisture for rainfall. Likewise the winds from the east in crossing the Rocky Mountains are chilled and their water is condensed as rain, to flow eastward into the Mississippi. The winds in the great plateau are usually drying winds which pick up moisture rather than give it up as rain. The conditions for precipitation in that arid region are good, except that at most times there is not enough surcharge of water in the clouds available for precipitation. The ground gets heated during the day, causing a warm current of air to rise, and this, if humid, would—on meeting the colder currents above—be chilled and cause a condensation, with probable rainfall. The rainfall from such condensation can often be observed on the desert, although no rain may reach the ground. A comparatively cool dry air stratum forces its way below the warmer air and absorbs the rain as it falls, before it reaches the earth.

A. P. Davis, chief engineer of the U. S. Reclamation Service, estimates that the Salton basin would receive annually from the Colorado river about 8,000,000 ft. of water per acre and he allows that evaporation would be seven feet in depth per year. At that rate the Salton basin would never fill. With an inflow of 9,000,000 acre-feet and an evaporation of six feet per year, it would take from forty to fifty years to fill the basin so that it would have an outflow to the Gulf of California.

The Colorado river is one of the largest rivers in the

United States. It is over 1,100 miles long, exclusive of its tributaries. With Green river, its northern tributary, heading near the Yellowstone Park, Wyoming, it has a length of 2,000 miles. The Colorado watershed is over 250,000 square miles, a territory equal to the combined areas of the States of California and Colorado. It is impossible to determine accurately the rainfall of this watershed, but the run-off of the Colorado river represents 20% of the total rainfall. If this water of the Colorado is allowed to evaporate in the Salton basin, it will mean that much more moisture available for rainfall in that area, and such water will evaporate, to fall again and again as rain in a never-ending cycle. As the winds cannot get into the desert without first leaving their excess of moisture in their drag across the mountains, neither can they get out again without leaving the water on the plateau or on its many mountain ranges. To what extent this will increase the rainfall no one can say, but it is more than probable that it will affect it to an appreciable extent.

Mr. Bailey speaks of the rainfall of 1884. In November, 1883, I rode a mule across the desert by way of Yuma, New River, Indian Wells, and afterward on to San Diego. It was very wet at that time. We camped two weeks under a mesquite tree near the Salt river, Arizona, waiting for the rain to cease, but finally we broke camp in the rain and rode on. It rained nearly every day until we reached Indian Wells in the Imperial valley. The New river showed signs of a recent overflow. There were salmon and other fish in the lagunas and at Indian Wells on the lake we found thousands of gulls and wild ducks. We killed ducks nearly every day on the trip. Southwest from Yuma, along the Colorado river, for miles we rode through an immense water-melon patch, formed by seeds distributed by the Colorado overflow. We were told that the Colorado river had overflowed the season before into the New river.

ALBION S. HOWE.

San Francisco, April 5.

Black Sand.

The Editor:

Sir—Having read your editorial on 'Black Sand,' in a recent issue, and being very much interested in this matter, I should like to record my experience. It is not my intention to begin an argument, but to make just a simple statement of facts. My first experience with fine gold and black sand came three years ago when I was associated in the operation of some placer claims on the head of Clarks creek, in Josephine county, Oregon. The bank was high, easily washed and the machinery (while I believe it could have been improved) was as complete as those in ordinary use for placer mining. I believed that the bank contained a value of ten cents per yard, with large quantities of black sand, amounting to from one tenth of one per cent to from three and one half to four per cent of the mass, giving an average of about one half of one per cent throughout. The clean-up was unsatisfactory, and the difference between our expectation and realization led us to investigate the matter. We placed a settling-tank under our apparatus and saved the sand from the clean-up, amounting to some hundreds of pounds, and sent a sample to Baker & Co., of Newark, New Jersey, for a test, from which they gave us a return of 35 oz. gold and 5½ oz. platinum. This led me to the conclusion that by two operations of this separation, the first consisting of separating the black sand from the pulp, and then making a final treatment of the black sand, it would be possible to make a good property out of an indifferent one, and I decided to devote my entire attention to accomplishing this result, or satisfy myself of the impossibility or impracticability of my endeavors. With this aim in view I visited a number of localities to find the one best adapted to an operation of this kind, and the one that would prove the most valuable in case a success resulted. And I am satisfied that I examined property now standing idle and considered of no value, that were they supplied with proper equipment, and this equipment properly adjusted, and the same judgment used that is often necessary to make the operation of a quartz proposition satisfactory, the results would be surprising.

I will give two illustrations. I wished to secure one ton of black sand to get an idea of the cost of securing it, and to prove the possibility of securing sand in large quantity. The cost of labor, supplies, etc., to secure this amount was $180. The rig was very crude and included the cleaning of the sand in a hand-pan. I separated all the gold possible, and a much larger amount than is possible on a larger scale, spreading the water over a wide surface covered with burlap under a screen. This I cleaned up frequently. The result of this experiment showed $43 in gold and one ton of sand that gave an average of $51 in gold from twenty-eight tests made, with platinum and nickel in such quantities that I cannot demonstrate the possibility of their profitable extraction.

In another case I had three tests made on a beach deposit. Samples were taken on a shovel without concentration. No. 1 fire test, $3.60 per ton, in gold; No. 2, fire test, $3.15; No. 3, amalgamation test, $2.40. This deposit is six feet thick and is 20 acres in extent to my knowledge and the indications are of a much greater area with possibilities of greater depth.

I do not believe that any exaggerated claims or misstatement of facts will help us to solve these problems, and if there is no future possibility of successfully separating the metals that are deposited with and go with the black sand, the quicker we know it the better, and I would be very glad of any light on the subject from the readers of the MINING AND SCIENTIFIC PRESS.

L. A. MAXWELL.

Crescent City, Cal., April 5.

GYPSUM IN CALIFORNIA.—There are now four gypsum mills in the State, one at Amboy, one at Los Angeles, and two at Palmdale. Of those at Palmdale one is still in process of construction. The product of these mills is consumed in the State. It is used mostly for wall plaster, but a smaller amount is ground for fertilizer. Generally speaking, the gypsum runs from 54 to 90% pure. Deposits occur, however, in the form of alabaster, which are very pure and are suitable for the manufacture of plaster of paris, but they are far from railroads, and so at present they are unavailable. The deposit at Amboy is found in the middle of the Mojave desert, along the tracks of the Santa Fe railroad. The plant is situated near the bed of an old lake, around the edge of which the gypsum has been deposited.

Gypsum sets quickly, usually in about five minutes. Because of this, a retarder often consisting of slaughter house refuse, dried and powdered, which delays the setting from 50 minutes to two hours, is employed. There is nothing peculiar about the California gypsum, as distinguished from that of other localities, except the fact perhaps that at one of the plants it is necessary to re-grind the gypsum after calcining it. California producers are fortunate in being able to use oil as a fuel in their gypsum mills. Not only is it a cheaper fuel than wood or coal, but it is better suited to the exigencies of the work, as the heat of an oil flame can be more easily and quickly graduated than can that of furnaces burning wood or coal

The Geology of the Veta Madre.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

An idea of the general geology of the Guanajuato district is obtainable along the road that crosses La Bufa. I went this way to the Peregrina mine, seven miles from the city of Guanajuato, and incidentally formed my first notions concerning the country enclosing the Veta Madre.

The accompanying cross-section (Fig. 1) I owe to Señor Ponciano Aguilar, of the Mexican Geological Survey. It illustrates the fact that the Veta Madre follows a fault of big throw, so that the foot-wall is shale[1] and the hanging a series of layers of volcanic fragmentary material. The magnitude of the fault that made the Veta Madre is clearly indicated.

The Miocene agglomerate of the hanging wall, usually called the 'red conglomerate,' or Guanajuato formation, is overlain by breccia and rhyolite tuff, termed 'sandstone' by the *outlanders*, while the Mexican geologists call it *lozas*[2]. Then comes more agglomerate and then tuff, the latter a succession of layers of volcanic fragmentary material, altogether 1,200 ft. thick, and reminding me of the formation that prevails in the San Juan region of Colorado. On the further edges of the eruptive centre these clastic rocks are replaced by lava flows, of dense rhyolite. The foot-wall of the big lode, as seen in this section, is Miocene agglomerate, and different from the foot-wall rocks north of the Sirena mine; the change of formation being due to a cross-fault coming into the Veta Madre on its foot-wall side, producing a down-throw of the southern portion of the foot-wall rocks. This is illustrated in the accompanying drawing (Fig. 2), made from a sketch given me by Mr. R. H. Burrows, an experienced economic geologist, resident at Guanajuato. The Sirena mine is indicated at *A*; at *B*, the approximate relative position of the Valenciana mine, the throw is at least 6,000 ft., while at *C*, the place of the Cedro mine, the throw is probably 2,000 ft. The difference in throw is not effected by bending of either side of the Veta Madre, but by step-faults.

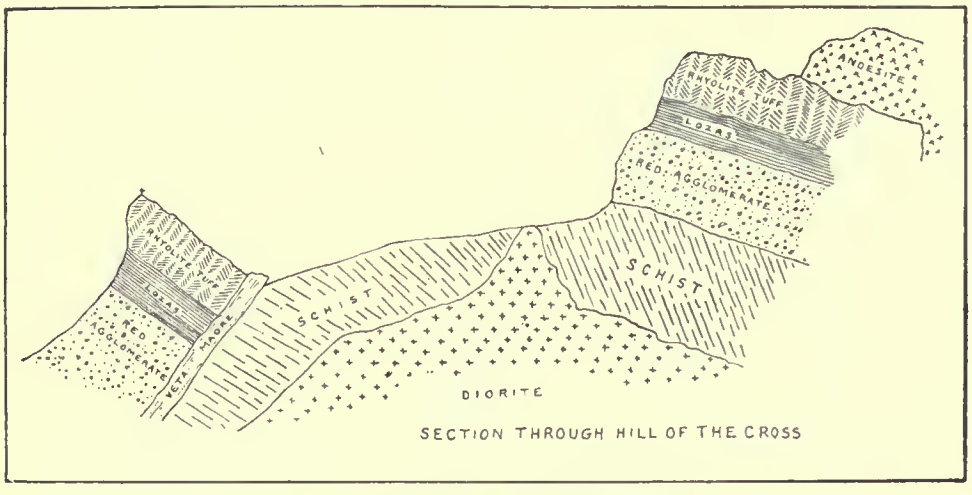


Fig. 1. Cross-Section of the Veta Madre.
After Ponciano Aguilar.

Northwest of this cross-fault it is difficult to determine the extent of the displacement along the Veta Madre, because the relation of the agglomerate to the shale has not been established. After the lode passes through the southeast of the cross-fault, the throw can be determined by estimating the distance from the top of the red agglomerate on the hanging-wall side to the top of the same formation on the foot-wall side. This distance is shown in the section *B B*, in Fig. 3, where it is represented as 2,000 ft. Referring to the section *C C*, there is no formation now in contact above or below the shale, and the bottom of the red agglomerate is nowhere visible. As the shale is older than the red agglomerate, the throw will be represented by the known thickness of the red beds, plus the amount of the latter that has been eroded on the foot-wall side of the lode. Of these two factors, which together make up the sum of the throw, only the first mentioned is definitely known. Starting downward from the top of the red agglomerate on Sirena Mtn. this formation is traced all the way to Marfil, a distance of six miles, exhibiting a constant strike and a dip varying from 5 to 30° east. The thickness thus represented is fully 6,000 ft., so that, omitting the other factor, it is well within the mark to estimate the throw at 6,000 feet.

At the Sirena mine, the foot-wall is shale (probably Cretaceous), varying from argillaceous to calcareous, from clay to lime. On the hanging the layers of agglomerate dip eastward toward the lode. The agglomerate becomes deeper as one goes southeast along the outcrop of the Veta Madre; it feathers out to nothing at the Valenciana, and at Bustos it is about 200 ft. below the bottom oe the valley. The slope taken at right angles to the strikf of the Veta Madre, is about 30° downward and toward the vein, the strata therefore making an angle of approximately 75° with the dip of the Mother Vein. The dip of all the bedded rocks in the district is about due east-west, and the strike of the lode is northwest-southeast. It is not a simple vein, but a vein-system within a zone 50 to 600 ft. wide. The principal orebodies in the Sirena mine occur near the intersection of the Amparo vein coming in from the hanging wall. Much the same is true of the orebody in the Rayas mine, formed at the intersection with the Santo Toribio vein, which also comes into the main lode from the hanging-wall side, the ore pitching with the line of this intersection.

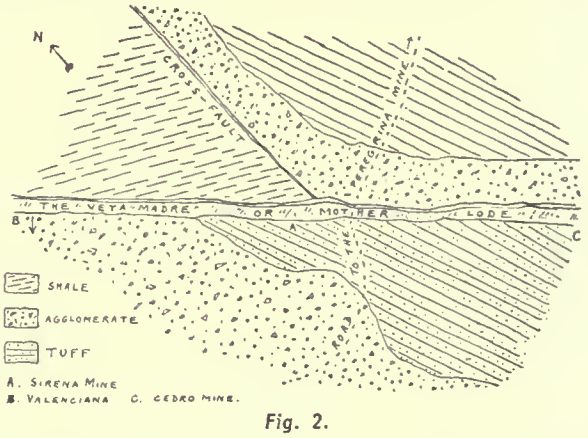

Fig. 2.

At the time of my visit, the Sirena was in bonanza; a new orebody had been found on the fourth level in a raise, where it touched the quartz of the old foot-wall

[1] The Mexican geologists use the term 'schist' for this rock, but it is a misnomer.

[2] *Lozas* literally means flagstones, it is a term applied to the water-laid volcanic dust, porous in texture and well stratified, which looks like a sandstone. It lies on the top of the 'red conglomerate' and below the other tuffs. The *lozas* constitute a thinly bedded formation of green rocks, only from 10 to 40 ft. thick. At some places the texture is fine enough to make them equivalent to a 'freestone,' eminently suitable for building purposes. The façade of the Juarez theatre is built of this material, and the ornamental stone-work all over Guanajuato is derived from this source.

stopes. At the fifth level — 800 ft. (along the vein) below the Purisima adit and 1,320 ft. from the outcrop — cross-cuts and raises had proved that there was 120 ft. of pay-ore, which, allowing for the diagonal course of the cross-cut and the dip of the lode, was equivalent to a width of 65 ft. Another cross-cut, 300 ft. farther east, had proved a width of 45 ft. One section showed three ore-streaks, parallel in strike, but converging in dip toward the foot-wall.

In Fig. 4 I have drawn a generalized cross-section of the Veta Madre as it appeared to me in the Sirena mine. *A A* is the hanging wall and *C C* is the foot-wall, *B B* is the lower limit of the main vein and is called the

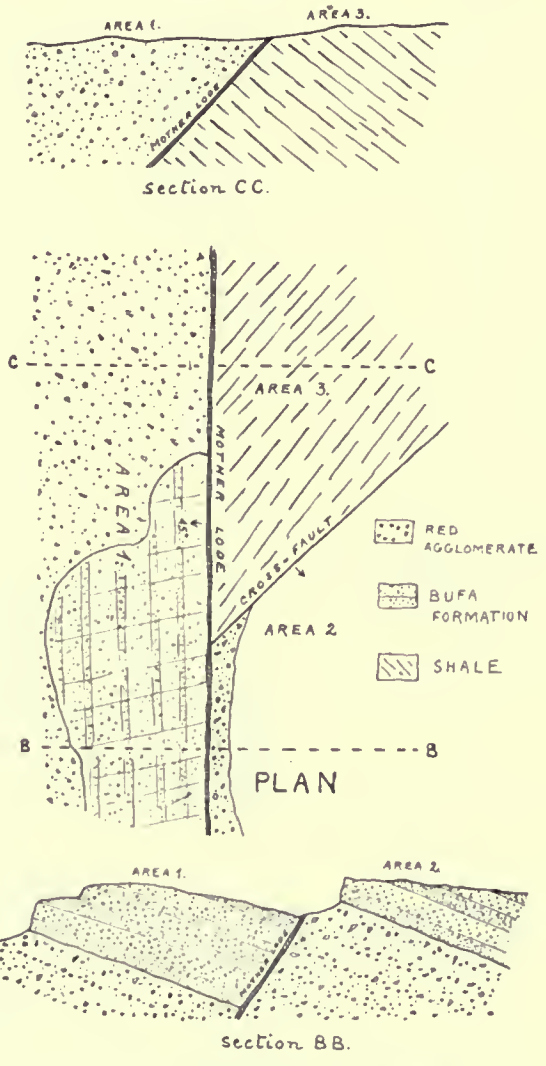

Fig. 3. Plan and Sections of the Veta Madre.

After R. H. Burrows.

intermedio, or intermediate wall. The distance between *A* and *B* is 25 to 75 ft., between *B* and *C*, 75 to 150 ft. On the foot-wall there is a vein, from 1 to 6 ft. wide, of quartz, which is not ore. The shale is bent near the foot-wall and is shattered between that line and the *intermedio*. *B B* represents the line of the fault, along which a width of shattered rock has created an ore-channel. Between *B* and *A* there are numerous stringers of quartz, some of which is ore, but the main orebody extends from the hanging into the agglomerate. The agglomerate does not wholly lose its identity by reason of impregnation with ore, and it is necessary to sample carefully in order to determine where profitable exploitation will cease. It is fair to say that the cyanide process has done more to widen pay-ore than the geologist, that is to say, the decrease in the cost of milling has enabled the manager to treat profitably material previously considered too poor. Where the lode is not rich the distinction between quartzified country and profitable ore is determined by the assayer, and not by the mineralogist.

I was informed that the orebody of the hanging wall, in the Sirena mine, was found while blasting for a cross-cut, intended to make room for a new hoist underground. The appearance of this ore suggests that it was formed by one of those movements that took place subsequent to the formation of the main fracture of the Veta Madre and its accompanying vein-matter; this latter movement evidently shattered the older quartz-filling and then proceeded through the hanging-wall country so as to make a big mass of brecciated ground, suitable for infiltration by mineral solutions, which re-cemented it with calcite and the more valuable metallic minerals. Diamond-drilling ought to be useful in exploring this ground; for the orebodies are large, but not connected. The old stairways and communicating passages appear often to be the bottom of underhand stopes,

Fig. 4.

and therefore suggest the lower limit of profitable ore at the time the work was done.

The geology of the Veta Madre has not received detailed study as yet, at least nothing has been published commensurate with the size of the subject, so that Humboldt's observations still possess a commanding interest. I shall quote from the old English translation already mentioned. He says: "The famous vein of Guanaxuato, which has alone, since the end of the sixteenth century, produced a mass of silver equal to fourteen hundred millions of francs,[3] crosses the southern slope of the Sierra de Santa Rosa." Beginning to touch upon geological matters, he states that "the most ancient rock known in the district is the clay slate (*thonschiefer*) which reposes on the granite rock of Zacatecas. It is of an ash-gray color and is frequently intersected by an infinity of small quartz veins. I consider this clay slate as a primitive formation, although the beds with very thin folia and which are surcharged with carbon, appear to approximate a transition clay slate. These beds (*hoja de libro*) are for the most part near the surface. On digging the great pit (*tiro general*) of Valenciana, they discovered banks of syenite or hornblende schist and true serpentine,

[3] £57,754,620 or, say, $285,500,000.

alternating with one another and forming subordinate beds in the clay slate."

Humboldt wrote in French, so that his use of the term *thonschiefer* indicates that he was thinking of the Erzgebirge, at that time—just one hundred years ago—the most scientific mining centre in Europe. His description of the shale, which constitutes the foot-wall of the Veta Madre, is right. It does exhibit a ramification of quartz veins. But the label 'primitive' will not do, for the formation is probably Cretaceous; moreover, 'primitive' is a word belonging to an outworn idea, that the basement rocks were the original cooled crust of the earth. Petrography knows no simple starting point; the rocks we see are only in a particular stage out of the many through which they pass in the course of their geological evolution. The modern geologist begins with the old crystallines, earlier than fossils. The undermost rock now known is a granitic batholith, which seems in places to have invaded the oldest schists. This granite may be an original igneous rock for aught we know, it is probably not a fused sediment, and is the nearest approach to anything 'primitive.' The crystalline granite, formed by slow cooling from a molten magma, when exposed to weathering at the surface of the earth, becomes disintegrated into sand and clay, which, being deposited in the ocean depths, are re-cemented and again solidified in process of time, passing through chemical and physical changes that make sandstone out of the sand, and shale out of the clay, at first, and then by further interplay of subterranean pressure, heat, and chemical action, these become on the one hand quartzite, on the other slate, with a mixed product of schist between them. The Valenciana shaft passes through the carbonaceous shale, with layers like the leaves of a book (*hoja de libro*) and penetrates the intrusive diorite, the decomposition of which, in places, gives the magnesian rock that Humboldt called 'serpentine.'

He continues: "Porphyry forms gigantic stony masses which appear at a distance under the strangest aspect, frequently like ruins of walls and bastions. In the country they go by the name of *bufa*. This porphyry, of which the Sierra de Santa Rosa is chiefly composed, is generally of a greenish color." Colors in rocks have ceased to have the importance they once had, for we have learned that the same rock can change its appearance while retaining an identity of composition. The name *bufa* still lingers at Guanajuato (but it is spelled with one f), and has almost replaced the higher sounding 'Sierra de Santa Rosa.' The sculptured summits and bold cliffs of La Bufa are due to unequal weathering of the rhyolite tuff that caps the Guanajuato series. Even in those days the term 'porphyry' played many parts.

Continuing, Von Humboldt mentions that "on the southern slope of the Sierra, the clay slate is covered with free-stone of very old formation. This free-stone (*urfels-conglomerat*) is a breccia of clayey cement, mixed with oxide of iron, in which are imbedded angulous fragments of quartz, lydian stone, syenite porphyry, and splintery hornstone." He speaks of the dip being opposed to that of the clay slate. Above this 'free-stone' there is "an agglomeration (*lozero*) of later date from which the finest hewn stone is manufactured."

The free-stone is a fine-grained tuff, used in the building of the city of Guanajuato, as already mentioned; it is soft enough to be easily worked, and yet hardens on weathering, so as to be durable. It is the *cantera* of the Mexicans. This formation occurs both above the shale of the foot-wall country, as Humboldt states, and also on the hanging-wall side; in fact, it marks the extent of the great fault of 1,200 ft., along which the Veta Madre was made. On the hanging-wall side the dip of the country is nearly at right angles to the vein, which cuts strongly across the bedding, and, for a long distance, follows a line along which the later tuffs and breccia are opposed to the shale. But on the outer edges of the mining district, the vein cuts through the younger rocks also. Humboldt saw this; he says: "The vein traverses both the clay-slate and porphyry. We have already stated that it has been wrought for a length of more than 12,000 metres; and yet the enormous mass of silver which it has supplied for the last hundred years, sufficient of itself to produce a change in the price of commodities in Europe,[4] has been extracted from that part of the vein alone contained between the pits of Esperanza and Santa Anita, an extent of less than 2,600 metres (8,529 ft.) In this part we find the mines of Valenciana, Cata, San Lorenzo, Animas, Mellado, Fraustros, Rayas, and Santa Anita, which at different periods have been very highly celebrated."

According to Humboldt, the European miners had been in doubt whether to consider the Veta Madre a "true vein" or a "metalliferous bed (*erzlager*)." He then proceeds to give some sound geological views:

"If we examine only the *veta madre* of Guanaxuato where the roof and the wall, in the mines of the Valenciana or Rayas, are of clay slate, we might be tempted to acquiesce in the latter opinion; for far from cutting or crossing the strata of the rock, the vein has exactly the same direction and the same inclination as its strata; but can a metalliferous bed which has been formed at the same period as the whole mass of the mountain in which it is found, pass from a superior to an inferior rock, from porphyry to clay-slate? If the *veta madre* was really a bed, we should not find angular fragments of its roof contained in its mass, as we generally observe on points where the roof is a slate charged with *carbone*, and the wall a talc slate. In a vein, the roof and the wall are deemed anterior to the formation of the crevice, and to the minerals which have successfully filled it; but a bed has undoubtedly pre-existed to the strata of the rock which compose its roof. Hence we may discover in a bed fragments of the wall, but never pieces detached from the roof."

The attempts to define a 'true vein' have not ceased even a hundred years after the above words were written; while the debate is adjourned and resumed at intervals by savants, the miner has disregarded such a nice point and has proved by his profitable toil that "metalliferous beds" are just about as good as the "true veins." The Calumet & Hecla, the Leadville orebodies, the Aspen contacts, the saddle reefs of Broken Hill, the lenticular masses of Rio Tinto, the disseminated copper deposits of Bingham and Ely—to mention only a few—are representative of occurrences that do not belong to what the schools of Saxony and Cornwall labeled 'true fissure veins.' Nevertheless, Von Humboldt's effort to distinguish between an ore deposit contemporaneous with the formation that encloses it, and one that has originated along later fractures crossing such rocks, is not without interest. He refers to the inclusion of rock fragments in in the *Veta Madre* in the following paragraph:

"Its extent varies like that of all the veins of Europe. When not ramified, it is generally from 12 to 15 metres in breadth; sometimes it is even strangled to the extent of half a metre; and it is for the most part found divided into three masses (*cuerpos*), separated either by banks of rock (*caballos*) or by parts of the gangue almost destitute of minerals. In the mine of Valenciana the Veta Madre has been found without ramification, and for a breadth of seven metres, from the surface of the ground to the

[4] An effect produced seventy years later, by the equally tremendous output from the Comstock lode, in Nevada.

depth of 170 metres. At this point it divides into three branches, and its extent, reckoning from the walls to the roof of the entire mass, is 50 and sometimes even 60 metres. Of these three branches of the vein, there is in general but one alone which is rich; and sometimes when all the three join and drag one another, as at Valenciana, near the pit of San Antonio, at a depth of 300 metres, the vein contains immense riches of an extent (*puissance*) of more than 25 metres. . * * * Valenciana is almost the sole example of a mine, which for forty years has never yielded less to its proprietors than from two to three million of francs (£82,506 to £123,759) of annual profit."

Here we have the Spanish equivalent of our term 'horse,' literally translated into *caballo;* it is the included rock that the vein rides, passing astride of it. If the branches of the vein do not re-unite, the result is a split or embranchment; if they come together, it is a 'horse.'

Dikes of andesite penetrate the agglomerate and the shale in various directions, and, as Mr. Robert T. Hill suggests, it is to them that we may impute the latest mineralization of the district; at least, it is probable that their intrusion along lines of fracture was coincident with a period of thermal activity. The Veta Madre, as a big width of rock sheeted by fractures near the contact of two unlike formations, afforded unusually favorable conditions for the penetration of ore-forming solutions, which followed the main fractures and spread outward and upward into the shattered agglomerate, where they found the inducement to precipitate the wealth of silver that is now suggested by the name of Guanajuato.

SPONTANEOUS IGNITION OF COAL.—Many coals containing a high percentage of pyrite are perfectly safe, and have never been known to heat seriously or ignite, while other classes of coal, practically free from pyrite, invariably suffer from spontaneous ignition under conditions favorable for its production. A careful study of the phenomena occurring during the heating of a mass of coal leads to the conviction that the pyrite present can only play a subsidiary part, and that it is in reality the absorption of oxygen by the freshly won coal, and the activity of the condensed gas in contact with the hydro-carbons of the coal that are the active factors in causing the ignition. In the seam the pores of the coal (for a trace of the original structure still remains in it) are filled with methane, or a mixture of methane and carbon dioxide, gases produced during the actions that led to the formation of the coal. When this coal is mined and brought to the surface, the coal exudes these gases from its surface, and in turn absorbs oxygen from the air. The action, however, cannot go on to any great depth in the coal, and while the pieces are fairly large no heat shows itself, but as the coal gets more and more broken by jolting during carriage and shooting into the ship's hold, the surface becomes enormously increased, and the mass of fine coal formed under the tip and below the hatchways in the ship is generally the spot at which heating and eventually ignition develops. The mere absorption of the oxygen, however, is insufficient to bring about serious consequences unless there be an initial rise in temperature to start the action, and in coal-cargo ships it is found in the enhanced air temperature in the tropics, in ship's bunkers by contact with the casings near the boilers, and in stores on shore by proximity to a steam-pipe or flue. In every case it was found that the spontaneous ignition of the coal started at the point where the cause of the initial rise of temperature was to be found.—Vivian B. Lewes, in *Iron & Coal Trades Review.*

Silver-Lead Smelting Practice.—III.

By T. S. AUSTIN.

Edited for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

*SMELTING OF OXIDIZED ORES AT CHIHUAHUA.—The plant consists of two 42 by 120 in. Fraser & Chalmers blast-furnaces, Root blowers, and a good Corliss engine; but the arrangements are poor and a number of minor defects appear. Some of these I can adjust, the others must go for the present, or until I have made enough successful running to warrant radical changes. The furnaces are good ones, and I want to make them run a large tonnage—as large as the endurance of the men will warrant. The ores are, first, a lead ore of Pb, 35%; SiO_2, 17%; Fe, 25%; and carrying 25 oz. Ag per ton; second, a low-grade dry ore of SiO_2, 35 to 50%; Fe, 10 to 15%; CaO, 10 to 25%; and containing 20 oz. Ag per ton. For fluxes we have a good limestone and an iron ore carrying a little silver. The proposition is a close one in some respects, and the profits must be sought in smelting the dry ore. I want to get a large tonnage through my furnaces. There will be some little matte, but not enough to keep a fore-hearth going, and I have overflow-pots that I expect to use. Of course in the old way I would put through 75 tons to the furnace, but I want to beat that record out of sight.

I am running two furnaces now quite well, but had a great deal of trouble at the start from non-reduction. This was due to the nature of the ore and to the low smelting-column. I started the furnace just as it was constructed, namely, with a thimble 3 ft. 6 in. below the floor-level, giving about 12 ft. 6 in. of smelting-column. I quickly pulled these out, and fed the charge against the sides of the furnace, but under the projecting charge-plates. The bad class of labor (with failure to feed properly to the sides) made this unsuccessful, and I then altered the furnace so as to have closed tops in the old-fashioned way. I lowered the hoods to within 18 in. from the floor, and bricked up to them, thus obtaining 16 ft. of a smelting-column. Thus I was able to get the furnaces under control, place the ore against the walls, and watch the feeders. Since the change I have got good reduction and good running. The ores are all coarse, and contain sulphates and arsenates, which make reduction difficult. I have no sulphides to lend their aid to reduction. I am now using about 18% coke on the charge, and, while I may get to 17 or even 16%, I do not expect to do better. The last figure I hope to reach only when I can get to bedding the ore, and obtain favorable slags for continuous runs. Just now I am from hand-to-mouth, and put on many a charge without analysis of some of its constituents—guessing, in fact. Of course our ore is pretty dry with an average of but two per cent of moisture, so the fuel percentage is not so bad considering. Probably with higher furnaces a lower consumption of fuel could be reached, but this is for later consideration, and I think that by January we shall get sulphides rich in silver. I am giving the preference to the whole-slag (1 to 1). Our ores are pretty pure here, so that the three constituents (SiO_2, FeO, and CaO) add up to 92%. This is no advantage, as I have to figure higher CaO and FeO in order to maintain the proper oxygen ratio. I figure the slag con-

*These observations of T. S. Austin, recently deceased, general superintendent of the Southern Department of the American Smelting & Refining Co., are compiled from letters written by him to his brother, from 1883 to 1906, covering most of the period of his wide experience in silver-lead smelting, and to some extent that in base-bullion refining. They lack some of his recent experiences, but show that much of his knowledge had been brought into finished form some time before his death. The notes refer largely to his work at Socorro, New Mexico, Monterey and Chihuahua, Mexico, and to El Paso, Texas, together with other technical observations made during that time. Professor L. S. Austin's remarks are in brackets. The previous articles of this series appeared in our issues of February 23 and March 16.

stituent at SiO_2, 35%; FeO, 28% and CaO 27%; and this gives me a slag of very acid characteristics. I would like to have more Al_2O_3, ZnO (if in oxide form), and MnO. The more the bases, the more fusible the slag, provided the RO bases are of a fusible nature. I am inclined to think that ordinary slags, resulting from varied mixtures, often contain the alkalies Na_2O, or K_2O, and are thus rendered more fusible. Ores containing porphyry, kaoline, etc., contain quite an amount of K_2O and Na_2O. However, I must work here until I can get a basis for future calculation.

Our main trouble now is the low grade of the dry ore, and also its scarcity, and unless we can change and improve this, we cannot keep going. I think, however, that we can get large quantities of the sulphides I mentioned, and, if so, the success of our plant is assured, as there is plenty of lead ore. Copper is a good removing agent, and so is plenty of lead—sulphides, however, are not so sure. I am doing pretty well, though, in this direction, for, with 9 to 10% lead on the charge, the slags run but 0.5 to 0.7% lead. I could improve this with 13% lead on the charge.

[In January, 1895, he writes:] I have been running the furnaces quite steadily and well, and now have matters in pretty good shape. Still I have plenty to do in detail, as I keep my smelting books in all branches, and this requires a certain amount of desk work daily.

I shall, when I get an opportunity, raise my furnace three or four feet, making them 20 feet above the tuyeres. I think the increased height acts more as a packing to make the furnace tight, and that low fuel is the result of having plenty of sulphides. I cannot believe that four feet more of charge, which the gases have to travel through, is capable of absorbing much, if any, more carbon monoxide from them, after the gases have reached this cooler zone of the furnace. In my case the increase of height would enable me to get the furnace tight, and confine the gases longer in the lower parts of the furnace, where the heat, and consequent reactions, are more intense. When the blast-pressure is raised, and other things (as speed) are unaltered, combustion (and with it reduction) are intensified at the point of admission of the blast. Of course, it is all very well to have the nerve to cut fuel, but, having had the nerve a number of times, and with very disastrous results, I keep to the quantity that experience has shown me to be safe, and, even then, "run on the ragged edge." With my practice (oxidized ore altogether) I do not have much variation from that of the early days.

In the absence of much RO bases I have to use more lime, and, in the whole-slag I am running, often get up to 31 to 32% CaO. My ordinary slag contains SiO_2, 35%; FeO, 27%, and CaO, 31%. It has every appearance of the acid whole-slag and in the pots, after cooling, the crystals show acicular forms, in fact I have not seen anything approaching a cubic crystal since I have been here, and would not know how to go to work to make them.

My experience in feeding is, that to get good results, one must charge the fine ore against the sides. Any device that would bring this about in an automatic feed would, it strikes me, be the most desirable. On the other hand, the very high shaft may obviate the necessity of this careful hand-feeding, simply from the extra high column of charges. I know that once you get to a certain height a couple of feet more will 'tighten up' a furnace wonderfully. My slags are of late too high in silver, due I think, to want of tightness in the furnaces. Formerly all my lime-rock came very fine and I could get the furnaces tight with it, but now I have to use broken rock.

[In May, he says:] I have just finished raising my furnace to 20 ft. over the tuyeres, and have just got one blower in and running, and I find I shall effect a coke saving. My main trouble is a tendency to over-tightness and packing, which will require watching. However, I think I shall soon get this correlated with the fuel, and effect a notable improvement in every way.

[By June he was running the furnace with good success and with some saving in fuel. He adds:] I find that three inches of mercury is sufficient blast-pressure when carrying the furnace full. My ore is, however, quite lumpy, and if it were not so, I would never have made this furnace so high. I am using but 8 to 10% lead on the charge and am carrying 15% coke.

SMELTING IN MEXICO is as cheap as it is in the States. This is natural, because the smelting talent and experience of the States has been transplanted there, and has at once inaugurated the best American practice. Competition on all ores is very close. This does not effect us very much as we handle our own ore and the low-grade is rather too low-grade to ship. Then we are well situated to load cheaply, to unload automatically, and to smelt with a small amount of labor and expense. With our compact plant and few officers, we work very cheaply in this respect. Our total labor and salary expense per ton of material is but 85 *centavos*, or 45 cents gold.

I am rather peculiarly situated. My furnaces are not connected to dust-chambers or flues, consequently the smoke and dust go off by the furnace-top. However, the ore is pretty lumpy, and I have a 20-ft. smelting column, so that, at times, the smoke is almost imperceptible, and dust is trifling. These furnaces are designed so as to make the just-named conditions incumbent on me, and I would not sacrifice feeding-height by carrying the charge much below the feed-floor level. I do not have to consider the roasting of the ore, and I suppose, never shall.

I only use two No. 6 Root blowers running at 110 rev. per minute for two furnaces, and get a pressure of from two to three inches of mercury—generally an average of two. With this I smelt nearly 100 tons of material per day per furnace, and this rate of running is about as much as my men can stand.

THE NEW CLASSIFIER designed by Robert H. Richards, has the following list of points in its design: A sloping bottom in a V-shaped tank, which gives the water current a gradually diminishing velocity. A grating along this sloping bottom is divided into sections, the earlier of which have a stronger rising current coming up through the holes, the later in the series, weaker. This handles the grains of ore systematically. If the grain has weight enough, it drops in the first hole, if not, it is jumped up and propelled forward, and when it drops again, it tries at another hole until it reaches the place where its weight is sufficient for it to settle into the hutch below. In addition to this sloping grating there is a larger tube beneath, which serves all of the holes. In the grating belonging to its section above, this tube has a sectional area equal to the sum of the holes in the grating above, so that the current of water rising in it has exactly the same velocity as that in them. It follows from this that any fine grains of sand that accidentally find their way down through the grating have a second chance to be treated in the tube below and to be lifted out and up to take their proper place, if they settle too soon. As a still further means of making for good classification, a vortex current is used along the lower end of this large tube so that the rising current on all sides of it are even. This is to prevent the descending currents that so often hurt classification.

A System of Ore-Bedding.

By the courtesy of E. H. Messiter, of the Robins Conveying Belt Co., we are enabled to publish the accompanying illustrations of a system for bedding ore, as applied in the smelter of the Greene Cananea Co. at Cananea, in Sonora, Mexico. The system has been highly successful, and therefore a few notes will be welcomed by metallurgists.

Fig. 1. Steel Bins and Shaking-Feeder Car, With Conveyor Underneath.

Fig. 1 shows a part of the system of steel bins into which the 25-ton cars from the mine are dumped. Different lots of ore are placed in separate bins. In the centre of the picture is the large self-propelled motor-driven shaking-feeder car, which serves to empty these bins one at a time, and to deliver their contents to the 30-in. conveyor, which runs along the ground under it. This conveyor, after leaving the bins, rises at an inclination of 20° to a point from which it discharges either to a gyratory crusher or directly to the next conveyor, which leads to the sampling mill. A sample is taken from each lot on its way to the beds. The ore then is carried to one of three conveyors, placed in over-head structures like the one in the centre of Fig. 2. These conveyors are equipped with a new type of fast-moving ore-bedding tripper, by the action of which the ore is uniformly distributed throughout the length of the piles, which is 400 ft.

Fig. 2. Beds of Ore. Conveyors in Overhead Structures. Reclaiming Machine at Work.

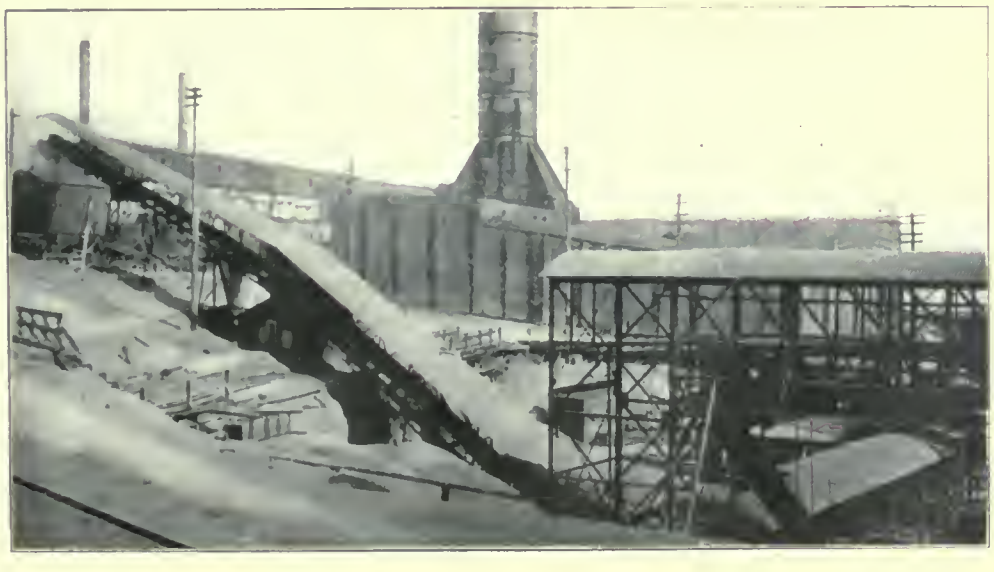

Fig. 3. Ore Conveyors, Delivering Mixture Direct to Furnaces.

A complete bed is seen to the left of Fig. 2.

The same photograph shows the reclaiming machine in action, having removed a little more than half of the bed. This machine attacks all parts of the cross-section of the bed in a perfectly continuous and uniform manner. As a result of the longitudinal uniformity produced by the ore-bedding tripper, and the uniformity with which the reclaiming machine excavates transversely,

there results a mixture that is remarkable in its regularity. At the time these photographs were taken, the machine was delivering a complete smelting mixture to the furnace. The machine travels ahead automatically at any desired rate, so that no attention is required in this operation other than that necessary for lubrication, and for the starting and stopping of the machinery.

Fig. 3 shows the end of the bedding-conveyor structures and the long inclined conveyor that carries the mixed charge up to the furnace-house, and also the horizontal conveyor for distributing to the several furnaces. The horizontal conveyor over the furnace-house is capable of delivering either to bins from which barrows may be filled by gravity with a complete charge, or of delivering the mixture directly to the furnaces without any wheeling whatever. The last procedure is clearly destined to be the regular method of operation.

Considering the storage system by itself, it is an interesting fact that this can be built at a lower cost than bins of the same capacity. This includes the cost of the reclaiming machine. When the extremely low cost of storing and reclaiming is taken into consideration, it seems that this system should be capable of wide application, now that its feasibility has been demonstrated by actual working. In fact, the bedding and mixing do not actually cost anything. There is probably no way in which the material can be stored and reclaimed at less expense, whether bedded or not.

Dedication of the Engineering Societies Building.

Written for the MINING AND SCIENTIFIC PRESS
By CHARLES S. PALMER.

Long before the readers of the MINING AND SCIENTIFIC PRESS may chance to light on this column they will have read in their local newspapers all about the formal christening of the really princely home given by Mr. Andrew Carnegie to the United Engineering Society as holder for the great national societies of mining, mechanical, and electrical engineering. And as good members of our own American Institute of Mining Engineers, we cannot avoid some quotum of interest in the change of the old headquarters from John street up to Thirty-ninth street.

The special dispatches in the newspapers have noted the program of the occasion, from the heavy and somewhat ambitious addresses to the technical papers, and modulating gracefully into the smoker and vaudeville of Friday evening. Each part in its way and place gave dignity or recreation to the interested visitors in appropriate way and degree; but an informal account of the exercises of Tuesday afternoon may perhaps serve to bring color and warmth to something that the daily press is only too apt to chronicle in a manner rather mechanical and perfunctory.

In the first place, the music rendered by a double string sextette, was distinctly select. "Such harmony is in immortal souls." This gave an elevated tone to the program of Tuesday afternoon. In the next place, one or two timely blunders gave a charming naturalness to what might easily have degenerated into a too formal affair. The maul used by Mrs. Carnegie in laying the corner-stone of the building was to have been used as the gavel for the dedication; but it so happened that it reclined behind an obstinate safe-lock which could not be coaxed to yield it, even for a loan. Mr. T. C. Martin, the president of the Engineers Club, read a telegram from Mr. John Hays Hammond, telling of his regret in being detained unavoidably, while all the while Mr. Hammond was on the platform and within arm's reach of the speaker. But these trivial incidents were a relief.

The opening prayer was delivered by the venerable apostle of sweetness and light, Edward Everett Hale, whose son was of the firm of architects that won the contract for the erection of the building on plain merit. Perhaps it was the consciousness of this fact that helped the grand old man to voice as simple and noble a petition as Providence ever heard from an association of technical scientists.

But Mr. Carnegie was easily the chief character on the stage. Here is a man who has all the temptation, and much of the opportunity, to 'slop over.' He might easily have betrayed an unpleasant, though pardonable, self-consciousness; a conceit, a pride, a patronizing assumption of superiority. But this man of diminutive physique, but of colossal generosity, this fairy-land benefactor, who is enjoying the fun of unparalleled giving, was as natural and as simple as a boy. He was at his best as he said: "When you see men uniting for the common good, there is union—solidarity; but when men unite against the common good—they can't trust each other"—and with a quick, disruptive gesture, Mr. Carnegie had the audience electrified. His graceful allusion to Mrs. Carnegie as a helpful planner with him was almost implied, rather than formally stated, but it was there; and it was felt. Mr. Carnegie's enthusiasm over the beautiful and practical results of the architects was as spontaneous as it was irrepressible; for it fitted in with the obvious promise of increased usefulness of the engineers to the world at large.

Charles W. Hunt made the impression of a tactful and forceful presiding officer, with suitable remarks for introducing each speaker in turn, and he was especially happy in introducing President Hadley of Yale as one whose training and vision gave him the advantage of looking through the present to the future. This educational executive, nervously full of expectant enthusiasm for his theme of technical worth and merit, combined with full observance for ethical standards of genuiness and helpfulness, gave another setting to the almost dramatic contrasts of the program. And it was well to listen to the dictum of academic teaching; but, as we left the hall, we could not escape the thought that after all, the foundation of it all ought to be, is, was, and will be, the serious work of the engineer. The engineer cannot always talk—sometimes he can hardly write; but he can plan great service, and he can translate it into accomplished fact.

The next time you and I are in New York City, let us remember that we have a new and an almost palatial technical home for study and research on Thirty-ninth street. It is close to the new home of the Engineers Club, only one block from the new City Library, and to the traveler by railway is as accessible from the Grand Central depot, or the *Times* square, as was the old place on John street. And the Santa Claus face of the giver has more reason than ever to add another genial smile to his countenance as he contemplates this new agent of concentrated helpfulness.

THE Heilungchiang gold mines, which ever since the Boxer trouble have been in the hands of the Russians, are to be handed back at cost to China. In this connection a Chinese Taotai, who has been appointed superintendent of the mines in question, accompanied by eight interpreters, and assistants, 20 miners from the Kaiping colliery, and a regiment of armed troops, has left Tientsin to take over the property. The party also took along 2,000 extra Mauser rifles, with sufficient ammunition to arm two other regiments, to protect the miners from lawless raids of Russian outlaws and Chinese mounted bandits. The mines are said to be exceptionally rich in the precious metal.

Feeder for a Tube-Mill.

Written for the MINING AND SCIENTIFIC PRESS
By N. C. GROCH AND F. J. NAGEL.

In a 16 by 4-ft. trunnion tube-mill having a packing gland on the feed end, it was found that the wear at this point was excessive, and after the feed-pipe had become slightly worn, it was necessary to shut down frequently to renew the packing.

To remedy this a small spiral pump (*A*) of the Frenier type, made of ⅛-in. sheet iron, was fastened to the mill in the following manner: A disc (*E*) of ½-in. iron, having a two-inch round hole in the centre, was bolted to the four stud bolts that formerly held the packing ring, to this disc was bolted one-half of a two-inch flange-union (*C*) into which was screwed a two-inch pipe (*D*) of such length that the body of the pump cleared the base that formerly supported the feed-pipe casting; to the end of this pipe was screwed another one-half of a two-inch flange-union (*C'*), which was securely bolted to the spiral pump.

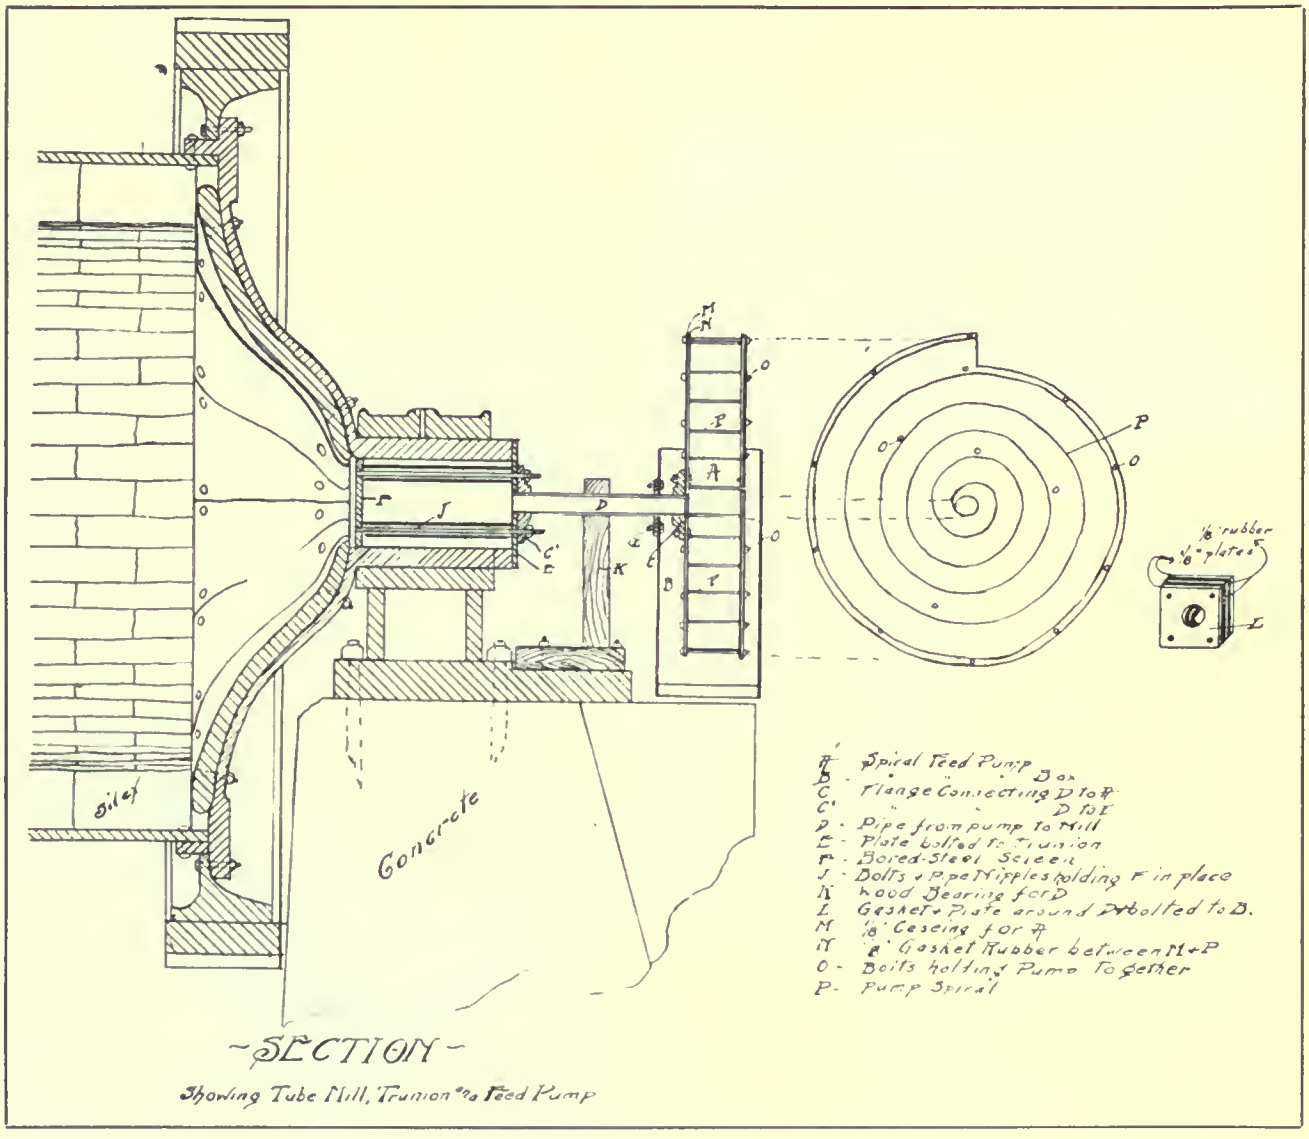
Gaskets of rubber packing were used in all places where leakage was likely to occur. As the pump was on the end of the pipe, a wooden bearing (*K*) was put between the pump and the tube-mill in order that the pump should not sag. The threads in the pipe have to be opposite in direction to the rotation of the tube-mill in order that the pump shall not be loosened by the friction of the sand in the box, in this case right-hand threads were used with a left-hand mill.

The pump rotated in a box into which the coarse pulp from the classifier was fed, the intake of the pump, scooping through this box, picked up the pulp and forced it into the mill, and worked equally well on water or thick pulp. As the pump picks up the pulp from rest, it is not essential that the cone or classifier be placed at the head of the mill; any place from which the pulp will flow to the box is sufficient.

As the pump is bolted rigidly to the mill, it will make the same number of revolutions; in this case 27 to 29 was found to offer no difficulties. The speed being fixed, and the diameter of the pump probably dependent on local conditions, the capacity will depend on the number of coils in the spiral and the width of the pump.

With the packing gland it was impossible to fill the mill more than half-full of pebbles, because the pebbles entered the trunnion, blocked the passage, and the pulp backed up; with the pump and a small perforated steel grating it was possible to fill the mill to any desired point.

While the principle involved, that is, a vertical spiral, is not new in tube-mill design, we do not know of any other feed equally satisfactory in its operation that has the following advantages: Adaptability to nearly all trunnion tube-mills; simplicity of construction; ease of inspection, and absence of wearing parts. All of which we think this device possesses.



A - Spiral Feed Pump
B - " Box
C, C' - Flange Connecting D to P
D - Pipe from pump to Mill
E - Plate bolted to Trunion
F - Bored Steel Screen
J - Bolts & Pipe Nipples holding F in place
K - Wood Bearing for D
L - Gasket & Plate around D bolted to B.
M - ⅛" Ceseing for A
N - ⅛" Gasket Rubber between M & P
O - Bolts holding Pump Together
P - Pump Spiral
Concrete

Feeder for a Tube-mill.

The Gold of the Snake River.

Contributed to the MINING AND SCIENTIFIC PRESS
By ROBERT N. BELL.

*In the past, the north shore of the Snake river, which forms the southern boundaries of Lincoln county, has given this division of the State of Idaho some standing in the production of gold, as that portion of the river was the scene several years ago of a successful gold-dredging enterprise, based upon the treatment of the extensive beds of gravel carrying the fine scales of gold, for which this stream is noted.

This was the operation of the Sweetzer-Burrows Dredging Co. of Minidoka, whose plant and its operation was described in detail in the report for 1904. The plant consisted of a suction dredge that ran several years and handled 3,000 cu. yd. per day, saving 90% of the gold content of the gravel raised from the low bars in the stream and along its borders between high and low water, where the gold concentrates at the short bends of the stream.

Ground-Sluicing on the Snake River, Idaho.

The company's operations commenced thirteen years ago, when it practically had the choice of the stream, and the results obtained, skimming the best layers of gravel to a depth of about six feet, averaged less than ten cents per cubic yard. After several years' continuous operation, which resulted in one $10,000 dividend, the enterprise was abandoned, because the margin of profit was too small. There has been probably $1,000,000 worth of dredging plants built along the Snake, but this is the only one that ever paid a dividend.

The counties of southern Idaho that border the Snake river report annually at the United States Assay Office at Boise the small shipments of gold derived from sluicing operations along the low bars, which border the stream for miles. These small operators are satisfied with two to four dollars per day per man, during the summer. They pick a favorable place along the first terraces, which rise 10 to 20 ft. above high-water mark, and afford a little dump, then build what is locally called a 'machine,' consisting of about 40 ft. of 3 to 4-ft. sluice, floored with a steel-punched screen in the first box. A sluice-head of water, generally derived from some of the big irrigating canals, is diverted to the ground and sluicing commenced through the flume. The first three to six feet below the soil generally carries the best pay. The fine material drops through the screen and is diverted at right angles on both sides of the sluice through a distributing box on to a series of inclined tables 4 ft. wide and 10 ft. long, covered with canvas or burlap, on to which the fine material is fed with plenty of water, and the gold and concentrate readily settle. About 90% of the gold and the heavy concentrate are caught on the first four feet of the tables; this is swept into a tray every few hours by diverting the pulp and turning on clear water. The concentrate and gold are stored until a sufficient amount has accumulated, to be run through a small *arrastre*, or grinding pan, in which quicksilver is added. The gold amalgamates perfectly after a few hours' grinding. This simple method, intelligently handled, will save 90% of the visible fine gold of the Snake river gravel. It is applicable, also, to big dredging operations and has never been improved upon by any patented process in practical use in this field.

Personally, I am sceptical about the invisible gold content of these gravel deposits, except the coated gold, which is readily recognized. The Snake river gold is finer than any natural placer gold I have seen. It is high-grade and worth $19.50 per ounce, but requires fully 1,500 colors to weigh one cent in value, yet under a powerful microscope, each color is an individual nugget showing abrasion. These particles are often coated, touched, or spotted with a crystalline white film of some foreign substance that looks like silica under the glass, and this is what makes it necessary to polish it in a grinding pan before it will amalgamate freely. The size of the particles range within comparatively narrow limits, but there is no gradual shading from the smaller colors into impalpable dust, and if the gravel contains any invisible gold that can not be recognized in an ordinary pan with the naked eye, it must be locked up in the particles of heavy concentrate.

The recent experiments of Dr. David T. Day of the United States Geological Survey at Portland, Oregon, on the heavy placer concentrates of the Pacific slope, to determine their value in other metals and minerals besides gold, including a number of samples of Snake river concentrate, which almost invariably yielded from a trace to quite an appreciable amount of platinum, but I doubt if many of the results obtained were from representative samples; and while the subject is an interesting one and well worthy of close and intelligent investigation, in the present state of the platinum market, I am afraid the particles of platinum are too thinly scattered along this stream. The actual contents of magnetite and

Sweester-Burroughs 10-in. Suction-Dredge; 3,000 cu. yd. Daily Capacity, on the Snake River, Idaho.

*This matter appears also in the Eighth Annual Report of the Mining Industry of Idaho. Illustrations donated by Mr. Bell.

similar heavy residues in these gravel beds, as nearly as I can figure, is from 0.5 to 0.75% of the gravel, and when their visible free and white coated gold content is properly amalgamated, the residue will not assay over five dollars per ton in gold.

I visited the point on Snake river from which the highest result in platinum was reported during the progress of the Portland Fair, which yielded platinum at the rate of 0.18 oz. per ton and several hundred dollars gold per ton, from the same sample, and learned that it was selected from the first burlap on one of the tables, with the fine gold left in, and probably represented a concentration of several thousand to one. A subsequent sample of clean black concentrate taken from below the grinding pan, after the free gold had been amalgamated, was sent to Dr. Day and gave a result of $3 gold per ton and only a trace of platinum.

The statements of irresponsible promoters that the Snake river gravel beds run from 25 cents to a dollar or over per cubic yard in gold are usually gross exaggerations; for while such material does exist along this stream,

Burlap Gold-Saving Apparatus at the Welsh Diggings, Near Blackfoot, Idaho.

it occurs usually in thin layers an inch or two thick, with a foot or two of comparatively barren gravel between the layers, and I doubt whether there exists a bed of gravel anywhere on Snake river that will average over 25 cents per cubic yard where a depth of ten feet is worked. There are some favorable areas where 10 to 15c. per cu. yd. can be obtained. The gravel is usually well worn and small and affords ideal conditions for dredging, with the exception of occasional layers of *caliche*, a semi-cement that dissolves readily when water soaks it a while. With a large enough plant and intelligent handling, these may be made to pay, but the possible margin of profit, working for the gold content alone, would be small and unattractive, unless there be gold or platinum, not apparent to the eye and to ordinary methods of saving, that can be recovered.

That platinum exists in metallic form, associated with the gold in these gravel beds, is not questioned, for while it can rarely be seen in panning, it invariably shows in cleaning amalgam. In the operation of the Sweetzer-Borrows dredge near Minidoka, it was always observed at clean-up time in gray metallic particles floating on the 'quick' when the hard amalgam was thinned for the purpose of separating foreign matter from the gold. A quarter of an ounce of clean platinum recovered in this manner is now in the possession of Lewis Sweetzer of Rupert, Idaho, one of the owners of the enterprise referred to. It is perfectly clean gray metal in scaly particles about as small as the fine gold.

I have gone into this detail for the purpose of putting intending investors in Snake river enterprises on their guard against exaggerated statements. People are often led into enterprises of this kind on the unwarranted promise of great profits; they lose their money and are ever after sore against the State. While it is possible that moderate profits may be made from the proper handling of these deposits, they are generally low-grade and exaggerated statements of their values should be liberally discounted.

ETHER.—The following daring conception of the ether was practically the last product of the brain of the great Russsan chemist Mendeleeff: Starting with the assumption that the ether possesses both mass and materiality, and by extrapolation inserting a zero group in the Periodic System, and a zero series of elements lighter than hydrogen, he deduced that in this series one element should have an atomic weight many times less than that of hydrogen, that is, less than 10^{-6} if H=1; it should have a monatomic molecule like argon and helium, and its exceedingly small density, or, in other words, the exceedingly rapid motion of its molecules, should enable it to permeate and penetrate all matter and space. This gaseous element he believed to be the ether, and he was satisfied that the recently discovered physico-chemical phenomena connected with radioactivity could be satisfactorily explained by assuming the emission of a portion of this ether and the entrance of new ether into the sphere of attraction of particles of normal mean velocity, if it were supposed that uranium and thorium, having the highest atomic weights among the elements, would have in the highest degree that power of attraction which lies between gravity and chemical affinity, and which would cause the accumulation of ether atoms round their molecules. This daring conception of the ether was practically the last product of the brain of the great chemist, and as such is now invested with a peculiar interest for those who are left to lament his loss.—*Chemical News.*

ZEOLITE is a term applied to those minerals that fuse readily with intumescence before the blowpipe. The more important of the zeolites are analcite, chabazite, harmonite, stilbite, henandite, natrolite, and thomsonite. They are related to the feldspars in constitution. They constitute a collection of finely crystallized minerals, and as such are valuable as specimens for mineral cabinets.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

Specimen from Garden Valley, marked J. E. L., not received.

From Caliente, Cal., specimen marked C. F. B., has not arrived.

C. T. D., of Searchlight, Nev., sends a specimen of granular black Tourmaline.

The specimen sent by S. B., of Victor, Colo., is a mixture of Quartz, Garnet, and Magnetite. Of no value.

The silicious powder, Tripolite, from Cripple Creek, Colo., marked R. H. T., has but little market value at present.

A. F. D., of Penticton, B. C., sends Feldspathic sand. It is of no value for making cement, but should make concrete.

Replying to J. A. McD., of Olalla, Canada. 'Garnitite' is not a recognized name of either a mineral or rock. Biotite granite is called granitite.

The samples from Ibapah, Utah, marked J. S. L., are: No. 1, Topaz; No. 2, Hematite; No. 3, Hematite; No. 4, Cherty rock, containing brown Mica and the green Copper silicate.

The specimens from Wonder, Nev., marked W., are: No. 9, Biotite Andesite; No. 10, compact Chlorite mass; No. 11, Rhyolite; No. 12, purple Fluorite, color due to Manganese; No. 13, contains the black oxide of manganese, Pyrolusite; No. 14, Manganese oxide; No. 15, Rhyolite; No. 16, rock stained with Manganese oxide; No. 17, Shale; No. 18, Quartz stained by the oxides of Iron and Manganese; No. 19, Biotite Granite.

The rocks from Coon Gulch, New Mex., marked H. A., do not admit of specific classification, owing to their metamorphosed and mineralized character. No. 1, serpentinized Metamorphic with Pyrite; No. 2, silicious Metamorphic; No. 3, altered Rhyolite; No. 4, chloritized rock; No. 5, Breccia; No. 6, 7, and 8, altered Volcanics; No. 9, Obsidian; No. 10 and 11, Metamorphic with cubes of Pyrite.

PRECIPITATION OF GOLD.—In the electrolytic precipitation of gold it is customary to use lead foil strips for cathodes, and iron sheets as anodes. The voltage between terminals is usually from two to three volts, and the best current density is found to be about 0.5 amperes per square metre. The gold is then deposited on the cathode in an adherent layer, and the lead cathode can be melted down. In the course of time fouling of the solution takes place by the formation of prussian blue and iron oxide at the anode. The substitution of lead, coated with lead peroxide, for the iron anodes has proved a failure, because of the formation of lead cyanide. Experiments show that at the start of electrolysis, very little gold is deposited during the first hours. This is due to the condition of the electrodes. Later the efficiency reaches a maximum, but any interruption of deposition causes a decrease in the rate of deposit. The efficiency of deposition is by far the greater, and the deposit firmest with a low current density. The efficiency varies from a fraction of one per cent to over seven per cent.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

A grant of the right to mine and remove coal and to exercise the ordinary privileges of ventilation and drainage on the land of the grantor, with the right to transport other coal through underground entries, in the coal before granted, with the right of way for an inclined railway, and the right to use one acre of ground at the mouth of the pit and land for siding and switches along a certain railroad, was held not to give the right to sink a ventilating shaft in the land of the grantor, to ventilate mines under adjoining lands.

Cubbage *v.* Pittsburg Coal Co. (Pa.), 65 Atl. 797 (Jan., '07.)

A land-owner may drill an oil-well at any place on his own land, though this may draw from an oil-well on adjoining lands. The only remedy of the adjoining land-owner is to drill a well on his own land. But where the same person holds oil-leases of two adjoining farms he will not be permitted to combine with one land-owner to drain the oil from the well on his land to the detriment of the other land-owner.

Barnard *v.* Monongahela Nat. Gas Co. (Pa.), 65 Atl. 801 (Jan., '07).

A lessee of an oil and gas lease has the right of removal for a reasonable time only after he ceases operation, and after such time he cannot remove drive-pipe and casing that have become a part of the realty, and which cannot be removed without destruction to the wells and injury to the real estate.

Perry *v.* Acme Oil Co. (Ind.), 80 N. E. 174 (Feb., '07).

Pending the determination of a controverted mining claim, it was agreed between the parties that the adverse should be dismissed, and that, after the original applicant procured a patent to the claim, it could be conveyed to the contestant and others on demand and payment of a certain stipulated amount. It was held that the contract did not create a trust nor vest in the contestant any equitable title or interest in the property, but created merely the relation of prospective vendor and purchaser under an option contract.

Stevens *v.* McChrystal, 150 Fed. 85 (Nov., '06).

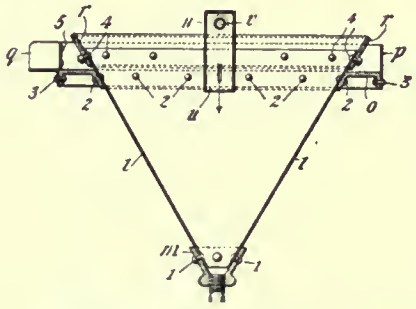
SILVER MINING IN CHINA.—Some years ago, says the *South China Morning Post*, a Chinese syndicate, with more capital than brains, started to exploit the Sam Cha silver mine in Kwai-Shen, which is about 300 miles from Wuchow. As no European mining expert was allowed to be employed, the enterprise turned out a failure. After an interval, a second syndicate was formed, but, owing to the same restrictions, it failed also. Over $1,000,000 is said to have been sunk in the venture, yet the mine is believed to be one of the richest in the world. Now the Taotai, at the request of the shareholders, has petitioned Peking to allow the services of a foreign expert to be retained, and this has been granted. A third syndicate has, therefore, been formed, and a contract entered into with a well-known Eastern banking company to advance money to obtain the necessary plant.

THE essential difference among the three processes for the lime roasting of galena is as follows: In the Huntington-Heberlein the ore is first partially roasted; that is to say, it is burned down to a content of 10 to 11% sulphur, and is then charged into the converter; in the Savelsberg process the ore mixed with the proper proportion of limestone and quartzose material is charged directly into the converter, there being no preliminary roasting; in the Carmichael-Bradford process the ore is mixed with a proportion of gypsum, and is then charged directly into the converter.

MINING AND METALLURGICAL PATENTS.

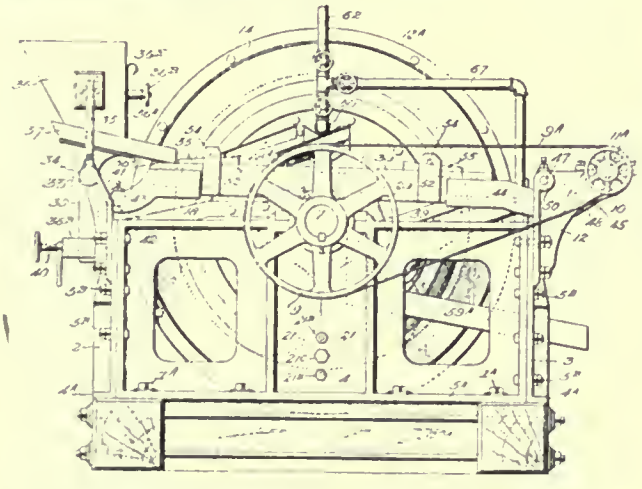
Specially reported for the MINING AND SCIENTIFIC PRESS.

CLASSIFIER.—No. 849,153; Charles W. Merrill, Lead, South Dakota.



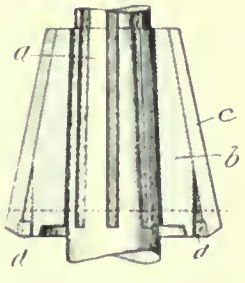
A static classifier consisting of a receiver having a main body of metal and a feed wholly within the periphery, and said periphery provided with an overflow-line composed of a thin strip of wood with the grain approximately horizontal.

ORE CRUSHING AND SCREENING MILL.—No. 849,037; Joseph Algert, Denver, Colorado.



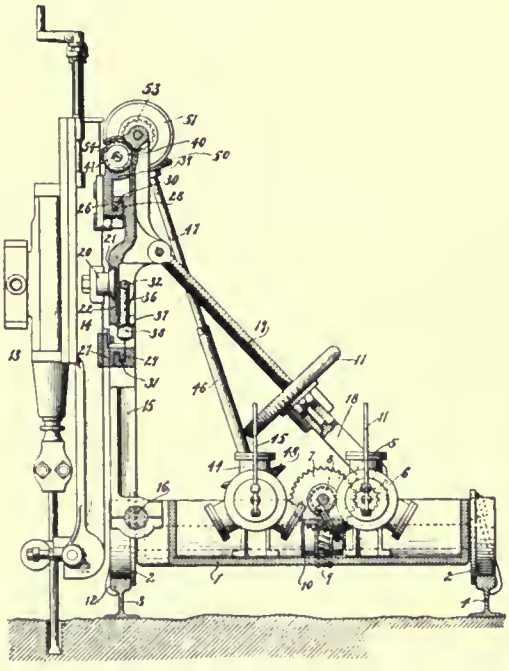
In an ore crushing and screening mill, a rotatable head having a flange on one side and a hub on the other side, a removable flanged-shaped ring attached to its opposite side having an introverted hooked-shaped inner peripheral edge, a divided circumferential ring having a recess-face fitting around said curved hooked end of said flange-ring, a shaft extending through the hub of said flanged portion, and means for supporting said divided flanges, and said divided circumferential ringing in a rotatably substantially water-tight joint on said hooked inner peripheral edge of said flange-ring.

ROCK AND ORE CRUSHER.—No. 848,782; George H. Thurston, Johannesburg, Transvaal, assignor to Allis-Chalmers Company, Milwaukee, Wis., a Corporation of New Jersey.



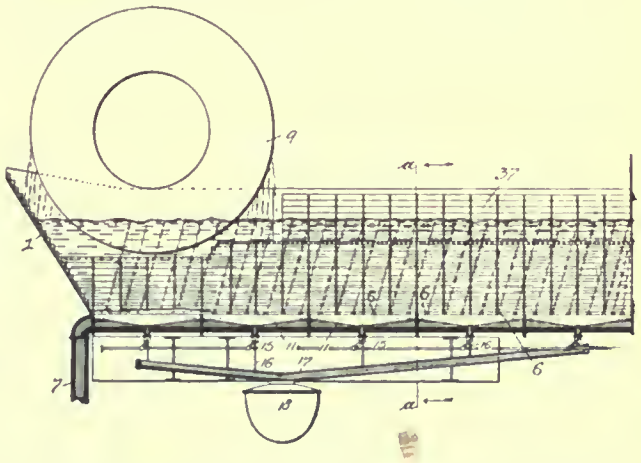
In a rock and ore breaker, a crushing-head comprising a core portion of relatively soft metal, said core portion having an inclined outer surface, a mantle of relatively hard metal closely fitting the core portion, and an inwardly projecting lug having an inclined face, said lug being located at the lower edge of the mantle, and said core being provided adjacent its lower edge with a vertical groove having inclined wedge portions for engaging the lug on the mantle.

CHANNELING-MACHINE.—No. 849,019; William Prellwitz, Phillipsburg, N. J., assignor to Ingersoll-Rand Company, New York, N. Y., a Corporation of New Jersey.



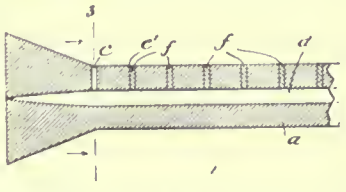
A channeler comprising a wheeled truck, a drill pivoted thereon, means for moving the truck to cause the drill to cut a channel to a predetermined point, and a motor connected to the drill for swinging it in the arc of a circle to cause the drill to complete the channel from said predetermined point.

GOLD-SAVING APPARATUS.— No. 849,101; Erastus S. Bennett, New York, New York.



An amalgamating-tank comprising upwardly flaring sides, mercury-containing pockets on the flaring sides, a bottom, a water-distributing conduit extending along said bottom, and having upwardly directed jet-nozzles, a plurality of depressions arranged at different points longitudinally of the tank-bottom, and each containing a body of mercury.

ROCK-DRILL.—No. 849,229; Frederick E. Glaze, Victor, Colo., assignor to The Eureka Drill Steel Company, Cripple Creek, Colo., a Corporation of Colorado.



A drill constructed with grooves and ribs, and a series of transversely disposed obstructions in the grooves, the obstructions being formed integrally connecting two adjacent ribs.

The Prospectus of the Truthful James Mining Company.

The directors of this company expect to make ten times their money out of the public, as they do not contemplate putting their own hard-earned money into any mining enterprise. So far the company has two mining properties, for which they paid a total of $130.

Property No. 1 cost them $100, and property No. 2, $30, besides two bottles of whiskey for the embarassed prospector from whom they bought the claims. Already about $37 worth of work has been done on property No. 1, at an expenditure of $480. The directors have also paid $5 to the mining expert for his report, and have promised to print 5,000 copies of the prospectus as an advertisement for him.

No veins have as yet been discovered on the property, but one fine wall has been found to which a small stringer of smaltite was attached, which one mining expert pronounced calcite, and which, he said, would undoubtedly lead to rich silver values at depth. The property is only 6,559 ft. 3¼ in. from the Woolly Wonder mine, whose vein our expert has traced over on our property.

The company has spared no expense in securing the services of Mr. Lieswell, the mining expert, who graduated with honors at Fakerburg in 1837, and who has had 102 years and three months' experience in this branch of mining.

We quote the following from our expert's report: "The country rock is a greenish gray calcareous peroxidite, heavily mineralized with hornaceous, schmisatic magaphone granite, and is cut by violent intrusions of pink felsnapthic andorite, with rhyolusic inclusions. This gives an abundance of contacts in the property, which will increase in value as they go down. Only one contact is still lacking, and your directors must arrange for that."

In conclusion our expert states: "This is undoubtedly the finest property I have seen in the camp."

We want it clearly understood that we are not responsible for any statements made by our expert; also that none of the directors are putting any of their money into the enterprise, but are relying on the public's money entirely to make it a success.—*Canadian Mining Journal.*

Trade Treatises.

THE WELLMAN-SEAVER-MORGAN CO., of Cleveland, Ohio, has just issued circular No. CA-3, of mine cages, skips, ore cars, sheaves, dumping-cradles, and similar machinery.

THE ECLIPSE DRILL SHARPENING MACHINE MFG. CO., of Denver, Colorado, has issued a pamphlet describing the new Eclipse drill-maker and shapener. Any size and form of bit in general use can be made on this machine.

THE DEMING COMPANY, of Salem, Ohio, sends us illustrated catalogue G, on 'Pumping Machinery.' This is an attractive catalogue, of 112 pages, describing the Deming power pumps, including single and double-acting triplex pumps for various services, deep-well pump heads, artesian-well cylinders, rotary and centrifugal pumps, and all sorts of electrically-driven pumping machinery.

THE CHARLES C. MOORE CO., of San Francisco, sends us a library edition of 'A System of Engines,' and products of Harrisburg Foundry & Machine Works, of Harrisburg, Pennsylvania. This is an elaborately gotten up little book, beautifully bound and illustrated, and one of the most handsome trade publications that we have ever received. It is devoted principally to Fleming engines and power factors.

THE MINNEAPOLIS STEEL & MACHINERY CO. is sending out a little booklet giving a general idea of the scope of its industry. This company reports that it will add another building to their plant. A short time ago they doubled their foundry capacity, and when the new building is completed, will have 12 acres of floor space. This company furnishes structural steel and does erecting, builds bridges, elevators, steam-engines, Munzel gas-engines and suction gas producers, and all sorts of power connections and appliances.

Publications Received.

'Examination Questions for Certificates of Competency as Mine Inspector, Mine Foreman, Mine Manager, Fire Boss, and Hoisting Engineer as given by the State Examining Boards, together with answers prepared and edited by the editors of *Mines and Minerals*.' First edition, published by the International Textbook Co., Scranton, Pa.; 568 pages, 99 illustrations. Price, $3.50. In the preface the gradual development of the mine laws in the coal mining States of the United States is traced, especially those leading up to the Pennsylvania law of 1885, which provided for certificated foreman, assistant foreman, and fire bosses in the mines of Pennsylvania. For many years *The Colliery Engineer* and *Mines and Minerals* have published each month a set of questions as given by the various examination boards throughout the United States, Canada, and British Columbia, together with answers by the editors. These questions and answers have been arranged, all duplicates taken out, and other questions which have been collected from time to time, but which have not been answered through *Mines and Minerals*, have been added. No questions have been introduced, however, that have not been given in a State examination. This compilation, therefore, faithfully represents the range of subjects and the character of questions given in examinations for certificated mine positions in connection with the coal mines of the United States and Canada during the last two years. The questions are often answered and illustrated more fully than a candidate for the certificate would be expected to answer them in an examination, as the book is intended to be of the most possible assistance to those preparing themselves for the State examinations. None of the general principles or theories have been given other than those asked for by specific questions, as the book is not intended to replace textbooks on mining, but to be used as a supplement to such textbooks. The position for which the examination was held, and the locality in which it was held, are denoted by italics at the end of each question, for, as far as possible, local questions have been answered in accordance with local conditions. Where the questions depend entirely upon the judgment of the one giving the answer, and not upon general theoretical considerations, an effort has been made when possible to check the opinion of the editors by submitting the answer to some member of the local mining board.

The section 'Suggestions to Candidates,' gives practical advice to those entering examinations as to how to carry on the work. The last chapter of the book gives very fully the regulations of the various States governing certificated mine positions, and this is the first time this matter has been brought together in a single book. A comprehensive index and cross-index, and an elaborate table of contents add to the usefulness of the book. The scope of the book is shown by the following chapter headings: Surveying; Geology and Prospecting; Mine Gases; Safety Lamps; Inspection and Regulation of Gaseous Mines; Explosives and Blasting; Elementary Principles and Calculations of Mine Ventilation; Comparison of Airways; Splitting Air Currents; Conducting Air Currents; Measuring and Testing Air Currents; Establishing a Circulation of Air in Mine Ventilation; Mine Fans; Practical Points in Mine Ventilation; Opening a Mine; Method of Working Coal Beds; Coal Pillars; Timbering; Steam and Steam Boilers; Steam Engines; Hoisting; Haulage; Hydraulics and Pumping; Compressed Air; Electricity; Duties of Mine Officials; Miscellaneous; State Regulations Governing Certificated Positions.

UNITED STATES GEOLOGICAL SURVEY. 1. 'The Cretaceous Flora of Southern New York and New England.' By Arthur Hollick. This is Monograph L, the number in itself being noteworthy. 2. 'The Analyses of Silicate and Carbonate Rocks.' By W. F. Hillebrand. This is Bulletin No. 305 and an important treatise. 3. 'Rate of Recession of Niagara Falls.' By G. K. Gilbert. Bulletin No. 306. An interesting pamphlet by a veteran geologist. 4. 'Water Supply of Nome Region, Alaska.' By John C. Hoyt and Fred F. Henshaw. Irrigation Paper No. 196.

Editorial.

ATTENTION IS CALLED to the fact that the offices of this journal are now at 667 Howard street, a few doors east of Third street, and close to the financial district of San Francisco.

MINING MEN will sympathize with the management of the Homestake in the difficulties caused by a fire in the underground workings. The decision to drop the waters of Whitewood creek into the mine, so as to drown the burning timbers, is heroic, and ought to prove effective, even though it entails a large expenditure of time and money. Incidentally we note that Mr. Thomas J. Grier, the manager, dismissed 500 men of that mixed breed known in the West as Dago, because they refused to go underground and fight the fire; only the American and English miners were willing to face the danger. We hope that the 1,000 stamps of this great mine may not remain idle long.

WHAT IS in a name? A great deal, if you want to suggest richness in a mine. For example, in South Dakota a mine formerly known as the Maitland, has just been re-christened the North Homestake; it is three miles from the Homestake; it is in the horizontal sedimentary formation of the Potsdam series, while the Homestake is in quartzose mica schist of Algonkian age and dipping steeply. The Maitland may be a good property, but it is Potsdam curious that it should try to borrow glory from the Homestake.

NEVADA now has a Mining and Scientific Society, the first regular meeting having been held recently at the Montezuma Club, Goldfield. The Society starts under good auspices; the president is Mr. John W. Finch, formerly State Geologist of Colorado, and now consulting engineer to the Goldfield Consolidated mines. It will be a State association of mining engineers and geologists. With so much of interest to observe and to record, the Society ought to make a name for itself. We wish it good luck.

AN UNDESIRABLE custom is creeping into technical and trade journals. Not content with giving an author's name as guarantee, with that of the editor, for trustworthy information, it has become the practice to add a foot-note stating the author's address and occupation, to the end, obviously, that he may obtain a little legitimate advertising. Next the modest foot-note becomes replaced by a longer introductory paragraph, which finally evolves into a wordy puff. As if this were not enough, we now have a picture of the author and a story of his life. A good article is its own recommendation, the editor's acceptance is another, the paper in

which it appears is a further indication of its character; the reader's intelligence should not be flouted by the methods of a patent-medicine vendor.

Copper Prices.

THE financial columns of the New York papers have had a good deal to say lately concerning the Metal Exchange in that city, and its quotations for copper. Wholesale criticism has been made and the metal trade is represented as "enraged" at the quotations of the Exchange, which are stated to be utterly misleading. While the quotations referred to are not authoritative and do not represent actual dealings on the floor of the Exchange, it happens that they are approximately correct and those behind the scenes know this to be the case, despite the rather loud protestations of several metal-selling agencies. We hold no brief for the Metal Exchange and consider it to be an organization of no particular importance, but we give some facts in order that those of our readers who are interested in the price of copper may not be misled by what they read in the daily papers. It is true that some of the large sellers, like the United Metals Selling Co., Phelps, Dodge & Co., and Calumet & Hecla, have not reduced their prices and are holding their copper at 25 cents and above, but this, under present conditions, means nothing more or less than that they are out of the market. As a result of the sharp break in the London market, it has been possible for some weeks past to import standard copper and other furnace material from Europe, refine it here, and sell it on the New York market at considerably below the nominal quotations of the aforesaid sellers. As a matter of fact, all business that has been done was effected at the lower prices, that is, around 24 cents at New York, for cash. The quotations of the Exchange are made by a committee of three, two of whom constitute a deciding majority, and the duty of this committee is to reflect in the quotations the actual transactions taking place from day to day. There is no business done on the Metal Exchange in copper, but the interests involved have always insisted that the Exchange as a matter of record should maintain a quotation for copper. That there should be so much protest against these quotations is difficult to understand because all the large sellers and buyers alike appreciate the situation fully, as well as the conditions that have brought it about. Needless to say, the disparity between the European and American markets cannot continue indefinitely, and if the large selling agencies and producers, like Phelps, Dodge & Co. and Calumet & Hecla, will persist in holding their copper until they can realize the price they are asking, the copper market will eventually have to go back to their figures, because their copper, or at least a good portion of it, is needed to fill the requirements. How long this state of affairs will continue we cannot foretell, but it can only be a question of time when, either by general lowering of values here or a rise in Europe, the conflicting factors in the world's markets will become reconciled. The industries at large have not as yet recovered from the late shock inflicted by the unpleasantness in Wall Street, and buyers throughout the country have become conservative and are inclined to follow a hand-to-mouth policy. This not only applies to copper, but to all other metals as well. On the other hand, there has been a revival in business in Europe and export sales have of late been made in satisfactory volume. However, the price realized has been on about a parity with the quotations of the Metal Exchange.

Labor Conditions in Nevada.

CONDITIONS underlying the employment of labor in the gold mining districts of Nevada present interesting problems to the mine manager. For instance, at Tonopah the union made a demand that surface men should work only eight hours instead of nine, the wages being $1 per shift for both kinds of work, on surface and underground. The operators did not see the justice of this and after negotiation between committees representing the two interests involved, it was decided to adopt a scale of wages, to be signed by the representatives of the operators' association and the miners' union. The leaders of the union objected to signing a three-year agreement, as it was contrary to the practice of the Western Federation of Miners. The operators refused to recognize the authority of an outside organization, insisting that their dealings were only with the miners working at Tonopah. So a general meeting was called by the union, to put the question to a vote. The mine managers stopped all work on the day of the meeting, so that the men might attend and no excuse be left for repudiation of the contract at any future period. The vote was favorable and the agreement was ratified. If matters have not been as pleasantly managed at Goldfield it is because of lack of unity among the operators and the excessive richness of some of the ore, making everything subordinate to rapid extraction. In a camp like Goldfield, the cost of mining becomes an academic phrase, for only the immediate profit is kept in view. One lessee went all the way to Chicago to buy a particular kind of hoisting engine that he wanted in a particular hurry; he chartered a special train and it cost him $6,000 to get that engine on the mine, but even this was justified by the short term of his lease and the richness of the ore that he was able to extract. Specimen ore provokes bad management and expensive ways; that is inevitable. Any saving seems so small compared to the daily variations in the value of the ore. It encourages stealing also. And at Goldfield, in the Mohawk mine, the stealing has been done in a reckless way. Men would come up from underground with $300 worth of ore and make no bones about it, for any fuss or attempt to search them meant a strike, and a strike would cause the cessation of exceedingly profitable mining operations, under leases the time of which was shortly to expire. Moreover, strikes are apt to be called in a summary fashion. Even the manager of a mine does not receive the courtesy of a notification, for the emisaries of the union walk to the shaft and order the foreman or shift-bosses to call the men from their labor and stop all work at once. These are among the conditions under which the production of gold is being made in the new El Dorado.

By the Way.

In connection with the recent earthquake in Mexico, we note that Mr. Robert T. Hill was interviewed recently by *The New York Times*. He said: The earth, one of the many millions of heavenly bodies, is supposed to be a cooling globe. It is also supposed, according to the best evidence obtainable, to consist within of an intensely heated 'protomagma' (the mother, interior substance) under great compression, consisting of all the known elements of universal matter, retaining the intense temperatures inherited from the time when the earth was a burning sun, and which has been incrusted by rocks, the by-products of its own combustion. As the interior substance and heat of the earth decrease through volcanic contributions to the outer envelopes of air, water, and rocks, the crust contracts and shrinks. The crust does not contract in all of its parts uniformly, however, but gives and wrinkles along certain great belts or zones of weakness, like a line of creases across a new-lain table cover. These folds, or pleats, occur along certain long lines or zones, thousands of miles in length and hundreds in width, and constitute the mountain systems of the world. The rock sheets along these zones also break, slip, and settle, making great fissures known as faults. The growing mountains are, therefore, the sites of great stresses and strains, which sometimes result in a breaking and giving way of such intensity as to shiver the whole earth. Such occurrences are known as earthquakes. The mountain ranges in different parts of the world follow different directions, and are largely of different ages. The great belts, or zones of folds and pleats, can be traced along or across the continents, but their continuity is lost at the ocean margin. It is not impossible to argue that in some instances these belts have extended nearly around the world, but usually when the geographer goes to making hypotheses of this character not founded on detailed fieldwork, he only succeeds in putting into scientific literature some great and almost ineradicable fallacy, like that of the continental backbone, which does not extend through all the Americas, as Humboldt alleged. Each great belt of wrinklings represents a geologic period of disturbance and contraction in the earth's interior. Some of the mountain ranges are very old, and quit growing many millions of years ago. In fact, some of them are so old that they have worn away so that they no longer appear as mountains, and in instances their former extent now lies beneath oceanic waters or has been obliterated by newer ranges crossing them. Movements have ceased along the sites of these older mountain systems, and hence the areas which they occupy are not subject to the great earth slips or quakes. The fact that New York lies in one of the belts of old and finished mountain making is the reason why geologists consider the city free from danger of violent shakes.

Millions of years after a great zone of pleating and fractures has been made on particular parts of the earth's surface and the movements have entirely ceased in that area, the earth begins to wrinkle in another area, and a newer mountain system begins to grow, with its axes in entirely different directions. The new belt, in turn, undergoes tremendous stresses of folding and earthquake, producing fractures, and ultimately completes its growth and ceases its groanings. Strips of the earth's surface have been wrinkled in this manner since the most remote geographic period, and are being wrinkled today. In the North American continent there have been many of these belts of mountain ranges at different intervals of time, three of which, however, are especially conspicuous and, in order of sequence, would be called the Appalachian, the Rocky Mountain, and the Antillean systems.

The Appalachian belt of wrinkles is the oldest, and its remnants dominate the easterly half of the continent. It was folded at the close of the coal-making period, which, upon the geographic calendar, is called Carboniferous period. This great system which, upon the map, apparently runs from New York to Alabama, in reality extended from Nova Scotia on the northeast diagonally across the continent in a southwesterly direction, across the Mississippi Valley, Arkansas, Indian Territory, and New Mexico to the Gulf of California. Its northeasterly end has been worn away, and the Atlantic Ocean now covers some of its former site. Its southwesterly extension was likewise degraded and buried beneath the waters of the Gulf of Mexico, which once lapped the shores of the Montana and the Nevada lands.

Millions and millions of years after the great Appalachian revolution, as it is called, the earth began to develop another belt of wrinkles, this time along the western half of our continent. It exteuded in a north-south direction, from Alaska to at least 15° of the equator, coincident with what is now known as the Rocky Mountain region, including the Mexican plateau. The last mentioned belt of wrinkles, or Rocky Mountain folds, has a north-south direction and must have been accompanied by quakes and volcanoes of enormous proportions, which mostly occurred at the close of the Cretaceous and the beginning of the Tertiary period.

In time the Rocky Mountains also ceased to grow, and rugged and wonderful as may seem their scenic phenomena, so far as the world's history is concerned, they are dead, decadent, and, geologically speaking, will soon be worn away. The north-south belt of the Rocky Mountain folds extends directly across the older Appalachian belt.

Still later our North American portion of the earth's crust started to wrinkle again, and this time along still different lines, in a curving direction from the west to the southeast, along the coast of California, across the north-south Rocky Mountain belt in Mexico, through the isthmus of Tehuantepec and Honduras across the Caribbean sea by way of the Mistirisoa and Honduras banks, to Jamaica, Cuba, Haiti, and Porto Rico. This great belt, so far as is traceable, is over 4,000 miles long, and extends from Cape Mendocino, Cal., to the easternmost of the Virgin islands, east of Porto Rico.

This belt is known to be over 1,100 miles in width, and extends from El Paso, Texas, the southern edge of the Colorado plateau, to the isthmus of Panama, the northern coast of Venezuela, and Trinidad. This belt of folding and faulting began as far back as Miocene time, perhaps a hundred million years ago. This is only yesterday in geologic time, which takes no account of years. Its movements have occurred progressively from north to southwest. This is the great zone of stress, strain, and folding movements, with the accompanying earthquakes which the earth's crust is undergoing today. The great quake of San Francisco, the Chilpancingo quake, and the Jamaica earthquake are its accompaniments.

Along this great northwestern belt will be found later geologic features of the western hemisphere, such as the Coast ranges of California, the modern volcanoes of Mexico, the isthmus of Tehuantepec, Panama, and the Great Antillean islands, and probably the oceanic islands of the Pacific. Some of the older features are the great southeast trend of the Rio Grande from El Paso to San Vincente, the southern edge of the Colorado plateau, the extinct, but wonderful volcanic foci of the little described Davis and Chisos mountains of Texas, the western Sierra Madre of Mexico, the remarkable quaquaversal ranges of northern Mexico and Texas, and the great overthrown mountains of Jamaica and the Great Antilles.

Personal.

C. S. HERZIG is in Spain.

ARTHUR L. PEARSE is at Salt Lake.

JAMES W. NEILL was at Kennett, Cal., this week.

H. E. WEST is in London, on his resurn from Siberia.

BLAMEY STEVENS is at Seattle, on a visit from Alaska.

H. R. PLATE has returned to Ely, Nevada, from Denver.

J. N. A. CONNER has returned to New York from Europe.

PHILIP C. STOESS is examining mines at Juneau, Alaska.

C. W. PURINGTON is expected at Denver from London on June 1.

E. W. BYRDE has returned to London from Kotchkar, in Russia.

S. R. MOORE has joined the Robbins Assaying Co. at Wallace, Idaho.

W. H. TREWARTHA JAMES has returned to London from Western Australia.

J. C. HAAS has opened an office as consulting mining engineer at Spokane.

J. B. TYRRELL is at Cobalt, Canada, sampling and valuing the Right-of-Way mine.

FRANK H. TEATS is now at Vanderbilt, California, with the Big 5 Mining Company.

BERTRAM HUNT is not going to West Africa, as was stated by our London contemporary.

GERALD M. BROWNE has returned from Australia to London, where he will remain.

FRANK H. PROBERT is examining the Yellow Jacket mine at Virginia City, Nevada.

W. B. THOMPSON, of Hayden, Stone & Co., New York, was in San Francisco last week.

P. G. BECKETT is assistant to the manager of the Capillitas Copper Co., in the Argentine.

R. J. GRANT and H. A. SHIPMAN are doing professional work in the Cripple Creek district.

S. F. EMMONS is making a geological examination of the Green-Cananea mines, in Sonora, Mexico.

J. GARFIELD SMITH was in San Francisco on his way from Wardner, Idaho, to Goldfield, Nevada.

H. W. TURNER is leaving Portland to direct mining operations at Kiam, Alaska. He will be absent two months.

ARTHUR F. HOSKING has been appointed Chief Reduction officer of the Tasmania Gold Mining Co. in Tasmania.

J. POWER HUTCHINS has been in the hospital at Paramaribo, Dutch Guiana, with malaria. He has recovered, we are glad to add.

ROBERT H. RICHARDS has just returned to Boston from Pennsylvania, where he has been advising in regard to iron and copper concentration.

GEORGE AMES, for several years cashier of the Utah Consolidated Mining Co., with headquarters at Salt Lake, has been appointed superintendent of the Ontario mine at Park City, Utah.

WALTER S. BROWN, of Wiard & Brown, Denver, is at present in Mexico on professional business. Upon his return he will remain for some time at the Cleveland-Arizona property near Red Rock, Arizona.

JANIN, STEBBINS & SMITH announce the dissolution of the firm. Messrs. Janin & Smith will continue as associated engineers at 804 Union Savings Bank Bdg., San Francisco; Mr. Stebbins will open an office at 1201 Chronicle Bdg., in this city.

WILLIAM YOLEN WILLIAMS with J. P. GRAVES, of Spokane, and formerly local manager of the Granby mines, at Phœnix, B. C., has been examing the Belcher mine, at Belcher camp, in company with J. P. Anderson, one of the leading stockholders of the Belcher Mining Company.

Books Received.

WEST AUSTRALIAN METALLURGICAL PRACTICE, written for the Chamber of Mines of Western Australia. A well arranged book of 200 pages, containing a description of the ore-treatment mills and processes of twelve of the principal gold mines of Australia, profusely illustrated with halftones, tables, and charts. The properties and plants described in detail are the Ivanhoe, Oroya Brownhill, Associated Northern, Sons of Gwalia, Kalgurli, Great Boulder, Perseverance, Great Boulder Proprietary, South Kalgurli, Associated, Lake View Consols, Golden Horseshoe, and Great Fingall, and the book is accompanied by 30 loose sheets of sections, plans, and working drawings. A most valuable book. Published by the Chamber of Mines of Western Australia, Kalgoorlie.

Dividends.

On May 4 the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 116 of $180,000. This makes the amount of dividends paid this year $900,000, and total to date $8,766,000.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

The site for the new Shattuck-Arizona smelter at Douglas has been chosen. The plant will be situated directly south of the Calumet & Arizona smelter. The smelter will be modern in every respect, and all the buildings, trestles, and ore-bins will be built of steel. Two furnaces, with a capacity of 200 tons per day, will be built.——A big machine shop will be built near the Junction shaft, in Bisbee, by the C. & A. and S. & P. companies.——Arrangements are about completed whereby the Wolverine & Arizona company will work its property through the abandoned Higgins tunnel.

GILA COUNTY.

(Special Correspondence).—The record made by the Old Dominion mine at Globe the past month in development and production of copper has been satisfactory. Most im-

Map of Arizona.

portant is the work accomplished on the 14th level. There has been a further enlargement of the big stope opened up in the sulphide vein from No. 2 cross-cut, from which about 200 tons of high-grade ore is being taken daily. The drift run in the vein for the purpose of giving better ventilation in cross-cut No. 3 is completed, and the driving of this cross-cut, which is now 40 ft. in fine ore, will be resumed at once. The main working drift has reached a point nearly 90 ft. beyond No. 3 cross-cut and a station is being opened from this drift, near the line between blocks eight and nine, where it is proposed to sink a two-compartment winze 200 ft., from which to develop the great sulphide ore-shoot at the 16th level. In sinking, a complete electrical equipment will be used. By the middle of the summer the first cross-cut on the 16th level will be in sulphide ore. B shaft is now well below the 10th level and connection will soon be made at that level with a shaft.——The Kiskey vein, near the east line of the Old Dominion, on the 10th level, is producing a fair quality of sulphide ore running about 8% copper, the entire drift being in ore of this grade. Development work is in progress to open this vein on the 11th level. The smelter record for the first half of April has been above recent averages. Four furnaces have been in commission much of the time and the daily output of copper is running over 400 bars.

Phoenix, May 1.

The Mineral Development Co. has notified the management of the Inspiration company that it will not exercise the option on the mine of the latter company.——At the Old Dominion, a winze will be sunk 200 ft. below the 14th level, to explore the new sulphide orebody. The Kiskey vein, near the east line, is producing 8% ore on the 10th level. Four furnaces are running most of the time at the smelter, and the supply of coke is increasing, 1,200 carloads having been recently ordered.

The operators in Globe are pleased over the announcement that the Southern Pacific will take over the Phoenix & Eastern road, partially constructed by the Santa Fe, and complete it to connect with the Gila Valley, Globe & Northern. This means that Globe will have a direct connection for both passengers and freight, to the main line of the Southern Pacific. The completion of the line from San Carlos to Winkelman is in itself a difficult task which will require much time.

PIMA COUNTY.

The Cleveland-Arizona property will ship ore regularly. The orebody on which they have been driving and cross-cutting for three weeks has shown up well and is all oxidized shipping ore, lying about 100 ft. below the surface. It is reported that the ore will run 18% copper. This property adjoins the Imperial on the north and west, and is owned by Cleveland, Ohio, men, and Percy Williams, of Tucson.

CALIFORNIA.

CALAVERAS COUNTY.

There is a chance that if the demand of the miners for an eight-hour day is not acceded to, a general strike will result along the Mother Lode. It is reported that the miners at the Utica, Lightner, Angels, North Star, and other mines at Angels Camp have made a formal demand for the eight-hour day, but have not asked for an increase in wages. The operators declare that such a change would destroy the profit and necessitate the closing of many of the mines, in which case about 500 men would be affected at Angels.

Later reports state that the miners have all struck. The vote stood 400 for the strike and 20 opposing it. The mines closed as a result of this action are the Utica, Matson, Stickle, Angels, Quartz, Crystal, and Lightner. The Utica management anticipated the strike and pulled all the motors and pumps out of the Gold Cliff, and the mules and motors out of the Cross shaft, and the company has a force of armed men guarding their property. This mine controls the situation, because its pumps handle most of the water for the camp, and when it closes the others fill with water.

ELDORADO COUNTY.

The water is now out of the 300-ft. level of the Alpine mine, and engineers will examine the property for George Wingfield, a speculator from Nevada.——The mill at the Standard Unit mine will soon start. The lower tunnel is being re-timbered.——Henry Koppikus has bonded the Clipper mine to New Yorkers. John Moore has started his quartz mill on ore from the Graydon mine.——Encouraging showings are reported from Le Boeuf mines. P. J. Stanton is in charge.——The Delwiseh mill has started again.——A cross-cut is being driven west to cut the lode in the Neptune mine, adjoining the old Trent mine on the south.

NEVADA COUNTY.

The Ethel mine, which has been idle for some time on account of water and a lack of fuel, has been opened again. Good ore has been developed in the property. Albert Maltman is the superintendent.——A small mill has been purchased by James Bros. for the mine on the Mother Mitchell ranch.——There have been encouraging developments during the last few days at the Mabel Mertz mine, a few miles from Forest City, and the old Emigrant channel has been encountered in a raise 1,900 ft. from the mouth of the tunnel. More than 6,000 ft. of tunnels and drifts have been driven to find the channel.——All top-men at Grass Valley have been given an eight-hour day by the mine operators. This change was given voluntarily, and includes blacksmiths, carpenters, helpers, and everyone working above ground. ——Good progress is being made in sinking the shaft at the Canada Hill mine, and a station will soon be cut at the

1,400-ft. point, and drifts run on the vein.——The property of the Blue Tent mine has been sold at a sheriff's sale.

SHASTA COUNTY.

Some difficulty is still experienced in the operation of the aerial tram to the Bonanza King mill, but the 40 stamps will soon be dropping regularly.——The Milkmaid, Wheeler, and Franklin mines at French Gulch have been bonded for $50,000 by Senator Jones and associates to the Western Exploitation Co., of Nevada, represented by H. F. Musser. A force of men is working there under Ed. Lewis. The Milkmaid produced $150,000 several years ago, and the Franklin is an old property, with a shaft down 100 ft.——The Mountain Copper Co. has announced an increase in pay for smeltermen at the Keswick plant. The men work eight-hour shifts, and there are 300 men on the pay-roll.——About 175 men are employed at the Blue Ledge copper mine, 30 miles from Yreka, and three miles south of the Oregon line. The mine has been under bond to the Towne company, of New York, for $150,000. This company has expended $200,000 in developing the mine, has run about 2,000 ft. of tunnels, winzes, and raises. The final payment on the bond comes due in two months.——The Mountain Copper Co. will prospect its fraction claim, near the Balaklala mine, by a three-compartment shaft that will be sunk several hundred feet. A boiler is being installed on the property, and 30 men will be employed. The first bent of the Trinity Copper Co.'s tramway has been raised. This tram will be completed in two months, and will then deliver 500 tons of ore per day to the head terminal of the Balaklala tramway that reaches to the Coram smelter.

SIERRA COUNTY.

Deep snow is still hampering mining operations in the higher altitudes of this county.——An attempt is to be made to consolidate a large number of claims near Alleghany. About 1,500 acres of mineral land, including quartz and placer locations, are involved in the deal.——A good vein has been opened in the Olivet mine, near Alleghany. This property is at the head of Kanaka creek.——A. C. Walters and J. W. Empfield have discovered a small piece of unworked gravel on Kanaka creek, from which they expect to get good returns.

TUOLUMNE COUNTY.

The litigation over the Slap Jack mine, which has caused that property to lie idle for eight years, has been settled, and the mine will be operated by the Yosemite G. M. Co., the same as before the shut-down. The last decision was rendered by the Supreme Court of the United States. The mine has a 100-ft. shaft and is well equipped with a hoist, compressor, pumps, etc., and a mill will be purchased.——A small crew is doing development work at the Mohican. The mill is not in operation, owing to the impossibility of getting fuel, and the road is impassable.——A new five-stamp mill has been purchased for the Ellen Winton mine. This property is owned by T. J. Crowley of San Francisco, and H. M. Stanley is the superintendent.——The contract for 100 ft. of driving on the Los Angeles mine has just been completed by Holland and Heinberg. A shaft has been sunk 110 ft. on this property, and three drifts have been run, aggregating about 1,000 ft., but it is thought that it will be necessary to sink deeper before a mine will be developed.

COLORADO.

SAN MIGUEL COUNTY.

A contract has been let to W. H. Mahon to complete the shaft from the Bullion tunnel, or seventh level, of the Smuggler-Union mine to the ninth level, which is the Pennsylvania tunnel, the lowest level in the mine. About 400 ft. of sinking remains to be done, and it is expected that the work will be finished in 90 days. The daily output of the mine has averaged 600 tons during the winter. Of this output, Robeson & Carter, the principal lessees, mine 300 tons per day, which is treated at the 60-stamp Smuggler-Union mill. Other lessees send their ore to the 80-stamp Pandora mill.——The material for the new Mayflower tram is being received. The tram will be two miles long and heavily built.

IDAHO.

IDAHO COUNTY.

(Special Correspondence).—E. C. Cummings, a Chicago capitalist, and Mr. Peacock, former manager for the Ladd Metals Co., have completed the arrangements for the erection of a 100-ton oil-fuel matte furnace, at Ruthberg, on the Snake river. This smelter will be used in the reduction of all minerals from the Heath mining district, and will work a great saving in length of haul for the operators in this territory.——A new placer field near the confluence of Elk creek and the American river, is being developed by E. A. Henshilwood, of Elk City. This field is near the famous old Grubstake placer, which for years proved a steady producer, first in the hands of the white man and later in the hands of the Chinese.——The development work on the Buster mine is being pushed by the owners. The mine is bonded to F. W. Bradley and other San Francisco parties. The cross-cuts at the 300-ft. level prove the lode to be 20 ft. wide, with ore of good quality. The east drift has now reached a point 75 ft. from the shaft, while the west drift has been driven for a distance of 65 feet.

Lewiston, April 27.

LATAH COUNTY.

At the Mizpah Copper Co.'s property in the Hoodoo district, the vein has been proved to be from 15 to 25 ft. wide and 200 ft. long. The value of the ore in copper is from $60 to $75 per ton. This is in the shaft. Three shifts are driving the tunnel, which has progressed 100 ft., and it will be necessary to proceed 700 ft. further before the orebody is reached, when a depth of 550 ft. will be attained.

OWYHEE COUNTY.

At Silver City, two shifts are engaged in cleaning out the adit on the shaft-house level of the Potosi, to drain the workings above. The tunnel is caved badly, making progress. Work in the No. 2 level continues, and the ore is looking good. On account of the bad weather, there is a good deal of trouble in getting the ore to the Addie mill.——The tunnel-level drift in the Banner is now in toward the south 100 ft., and the vein is widening. A drift on the same level has started north and has progressed 25 ft.——A company has been formed to work the Village Blacksmith claim, about one mile from Silver City. A tunnel has attained a length of 150 ft., and a two-foot vein carrying free gold has been developed.

SHOSHONE COUNTY.

(Special Correspondence).—The Frisco mine, one of the oldest lead producers in the Coeur d'Alene, gives promise of developing into a heavy shipper of zinc. Three thousand tons of concentrate awaits treatment by a magnetic seperator, installed on the upper part of the remodeled mill. Experiments show that the best results are obtained by applying the treatment after the product leaves the jigs. More than 15% zinc remains in the lead concentrate and experiments show that this can be reduced to 2%. It is estimated that when the two additional magnetic separators, already ordered, have been installed in the mill, the shipments of zinc will be nearly twice as heavy as the lead. Spokane electric power has been installed at the mine and the two pumps, one on the 1,600-ft. level and one on the 2,000-ft. level are being operated by electricity transmitted 100 miles. Sinking in the shaft is being continued and a station on the 2,200-ft. level will be cut in a few days. About 150 men are on the payroll.

A third dividend of $45,000 has been declared by the Snowstorm Mining Co., operating near Mullan. With the April payment of $45,000 the total dividend paid to date under the new organization amounts to $225,000. This is not all the mine had paid in dividends, for when it was under lease several years the payments amounted to more than $500,000. The treasury is in a condition to permit a larger dividend, but the management desires to retain a surplus. The shipments last month amounted to 8,600 tons, which netted an average of $10 per ton. The smelters do not make their remittances until 60 days after the receipt of the ore.——O. B. Wallace, the manager of the Interstate mine in the Coeur d'Alene, has samples of ore running well in gold, copper, and silver, taken from the No. 2 vein, and in

the 200-ft. drift. The company organized three years ago with three claims, and now has 23 claims. Thus far no ore has been shipped, but the managers expect to begin doing so in a few months. A sawmill will be built and a lower tunnel will be begun this summer.——The Superior Consolidated Mining Co. owns a group of 15 claims south of Osborn in the Coeur d'Alene. A well-defined vein crosses the holdings for a mile. A contract will be let at once for driving a 600-ft. tunnel, which, it is figured, will cut the lode at a depth of 400 ft.——Shipments of copper-silver ore will be made from the Carney group, south of Mullan, on the Wallace-Missoula branch of the Northern Pacific, early in June. The lower tunnel on the property is now in 250 ft. and has 400 ft. to go before it will cut the vein at a depth approximating 500 ft. The ore now ready for shipment was taken from the upper workings, where, at a depth not exceeding 85 ft., 33 ft. of ore averaging 4% copper and six ounces of silver, has been opened.

Spokane, April 27.

NEVADA.

ESMERALDA COUNTY.

An agreement has finally been reached between the operators and miners at Goldfield, and the men have returned to work. This has caused a rise in the market prices of southern Nevada shares, and a busy campaign will be started at all Goldfield mines.

Under the terms of the agreement signed by the union and the operators, the wage scale shall remain the same and eight-hour shifts shall continue; the miners' union shall have jurisdiction over all men employed around the mines, mills, and smelters, excepting superintendents and managers; no boycott or strike shall be declared unless by a two-thirds vote of the union; no town labor controversy shall interfere with the operation of the mines, or the employment of miners; and the terms of the agreement shall remain in force for two years.

LANDER COUNTY.

(Special Correspondence).— Tenabo has at present 300 inhabitants, consisting principally of miners. The town is growing steadily in population and number of buildings. A water system is now being laid out to supply water for both town and milling purposes. Not only is there a scarcity of building material, but labor is at a premium. Mine owners and others are unable to get enough men. Transportation from the Southern Pacific at Beowawe, 25 miles distant, is delayed by lack of teams.—— The Gold Quartz Mining Co., for which George M. Anderson is the manager, owns a group of 14 claims, and has been shipping ore for eight months. The main shaft is 150 ft. deep, with workings at the 35 and 100-ft. levels. The hoisting has been done by a whim, but they are now installing a 25-h.p. gasoline hoist. Upon resumption of work they will employ from 15 to 25 men. This company has let 12 leases on its various claims.

The Riggs-Lander lease on the Giant claim has made some rich strikes and has already shipped 15 tons of free-milling ore averaging $500 per ton. They have on their dump 150 tons of milling ore averaging $18 per ton, which is being held for the installation of a mill in the camp. The Phoenix Mining Co. is also a lessee from the Gold Quartz Mining Co. It has 30 tons of good ore sacked and ready for shipment to Salt Lake. The ore is chalcopyrite and arsenopyrite. This company has driven a tunnel 380 ft., and is employing 10 men. It has a 25-h.p. gasoline hoist on the way, and on its arrival, will sink a shaft from the surface to a depth of 600 ft. L. L. Trout is the manager.——The Gold Quartz Mining Co.'s Giant group of five claims will be patented immediately.

The Little Gem mine owned by Salt Lake men and managed by Hiram Tyree is a steady shipper and is opened to a depth of 375 ft., by an inclined shaft. Twelve men have been employed here throughout the winter, but water has been encountered lately necessitating suspension of operations until a pump can be installed. At the same time, a two-drill compressor and a larger hoist will be put in. This machinery will be in place within three weeks.——The Cortez Valley Mining Co., under the management of J. J. Cusick, is beginning operations on a large scale. It will erect a stamp-mill immediately, and will install a water system.——The Moose Mining Co., controlled by J. H. Brite and Wm. Myers, has struck rich ore on the Moose group at the 65-ft. level. This group consists of three claims, the Moose, Chloride, and Eclipse, and bids fair to become one of the best payers in the camp.

Tenabo, April 10.

WHITE PINE COUNTY.

The 2,700-ft. tunnel between the Ruth and Star Pointer workings of the Nevada Consolidated company at Ely, has been finished and the track laid. The Nevada Northern railroad is laying track up to the first railroad tunnel in Robinson cañon. The tunnel near Keystone, above Lane City, will be finished by the Nevada Consolidated Copper Co., which will transfer to this work some of the men who built the Ruth tunnel.——A Keystone drill is working on the Beaver claim near Ely.——The Ely Mines Co. is sinking a new shaft on the Badger claim.——A churn-drill will be

Map of New Mexico.

used in exploring the ground of the Manhattan-Ely. Harry Darlington is the manager.——H. B. Northrop has transferred the Paymaster placer claim to the Nevada United Mines Co.——The Tenderfoot group at Mizpah has passed to Myers & Lane.——The Chainman property is to be developed under the direction of G. E. Gunn. The old workings will be abandoned, and two new shafts will probably be sunk, particular attention being paid to the Joanna claim. ——Surveyors have completed a traverse for the line of the high-tension electric power line from the smelter power-plant at McGill, to the mines of the Cumberland Ely and Nevada Consolidated Copper companies.

NEW MEXICO.

COLFAX COUNTY.

Parties interested in the St. Louis, Rocky Mountain & Pacific railroad have purchased iron-ore deposits in Iron Mtn., near Elizabethtown. A large amount of ore is said to be available.

DONA ANA COUNTY.

Work has commenced on the new smelter to be built for the Torpedo mine, at Oregon.

RIO ARRIBA COUNTY.

A good body of copper carbonate has been opened at the 60-ft. level in the Whole mine, owned by Otto Rosenfeld. ——The Tusas company has been hoisting water from the lower levels of the Tampa mine, preparatory to starting sinking and driving operations. The reservoir, which furnishes water for the copper-leaching plant of the Tusas company, burst recently, but was quickly repaired and the mill is again in operation.

SAN MIGUEL COUNTY.

In the Rociada mining district there are many properties that have been quite extensively developed. The principal prospects of the district are: The Rising Sun, which is down 175 ft.; the Azure, 160 ft. deep; the Consolidated, with a 90-ft. shaft; the Loring, with a 125-ft. shaft and a 50-ft. tunnel; the Sam Adams, with a 60-ft. shaft and a 150-ft. tunnel; the Bessie, of the Tripod M. Co.; and the Alta M., M. & L. Co.'s No. 1 shaft, down 90 feet.

SANTA FE COUNTY.

There is a decided renewal of activity in the Cerrillos district. Mining men from Denver have been investigating the district and bonding ground, including the Cash Entry group; the Grand Central; the Mina del Tiro; and the Thomas Whalen claims. The ore carries lead and zinc, and it is stated that a concentrator will be built.

SOCORRO COUNTY.

Much work is being done in the Magdalena district. The Graphic and Kelly properties are being exploited, and each is shipping ore and will soon build concentrators.

OREGON.

UNION COUNTY.

(Special Correspondence).—Near the headwaters of the North Powder, about 25 miles northwest of Baker City, J. A. Thornson is developing a mine known as the Standard. The ore is quartz, carrying copper, gold, and silver. The vein is a fissure in granite, from two to seven feet wide, and the shoot has been proved for 400 ft. in length. It assays $33 per ton, and 650 ft. of work has been done, and a concentrating plant, run by water power, with a capacity of 10 tons per day, is about ready to start.—— Two miles below the Standard is the Royal group, consisting of three claims. On this property an adit has been run 800 ft. on the vein. High-grade ore has been encountered in this drift.—— In this district, which is just coming into notice, J. W. Messner, manager of the Indiana mine, has a promising prospect, which he is developing. The Indiana mine is on the western end of the copper belt. It is situated 25 miles northeast of Baker City. Thirty-two men are working at the Indiana. The management is blocking out 7% ore at the 300-ft. level, on a 30-ft. orebody, and is sinking another 100 ft. The pumps, hoist, and compressor are run by steam. —— The North American mine, which is one of the best-known properties on the belt, has suspended work for the present. This property was bonded a short time ago to New York parties for $1,500,000, but the deal fell through, and the company is now preparing to carry on the development itself.—— A sale is pending on the Gilkison property, to parties connected with the Bingham smelter in Utah. This property is the Copper Butte. It is owned by Jim and John Gilkison, and lies about three miles east of the North American. The purchase price under consideration is $50,000, and it is understood that the sale is assured.—— W. H. Harris of Indianapolis, Ind., has under bond the Van, Lone, and Cox properties on Goose creek, about five miles east of Copper Butte. He recently visited the camp with Chicago capitalists, and put a force of men to work in conformity with the requirements of his bond.—— On Coin creek, which empties into Goose creek, James A. Howard and associates have 15 men at work on the property of the Sovereign company, which they control. This property is considered a good prospect. The gossan capping is 100 ft. wide, and the tunnel, which they are driving to cut the vein at a depth of 150 ft., is now within 20 ft. of the ore. Much interest is centered on the result of this work, as 10-ft. holes sunk into the gossan at the surface expose the sulphides at that depth.—— To the south and east of the Sovereign, the country has been located for 10 miles, to the foot of Sparta butte.—— Activity on the eastern end of the belt continues, and a railroad is being built from Huntington, down the Snake river. The Iron Dyke mine, at Homestead, remains the centre of mining interest on the Snake. Nearly a million tons of ore are blocked out on this property, and the work is going steadily forward. The Iron Dyke is said to have been located, originally, as an iron mine, for the purpose of obtaining flux for the ores on the Idaho side of the river. The iron proved to be a capping, which gave place to copper at a comparatively shallow depth.—— In the various construction camps, between Huntington and Homestead, about 800 men are employed, and the Utah Construction Co., which has the contract for building this road, is endeavoring to increase the force to 2,000 men. Their difficulty is to get men who want to work. —— At the Ox Bow bend, on the Snake, J. D. Winslow is developing electricity to the amount of 25,000 h.p. He is completing a temporary plant of 500 h.p., but the work of adding to it will be pushed as rapidly as possible. Over 100 men are employed at this work, and more are being added to the force as rapidly as they can be found. Three parallel tunnels will pierce the Ox Bow from the Idaho to the Oregon side of the river, where the plant is being installed. The fall is 240 ft. Contracts for power have been secured for a radius of 100 miles out from this centre, and four outfits are equipping for setting poles and stringing wire along as many different lines, to the mines and towns within that area.——Pine creek, which heads in the Cornucopia district, empties into the Snake, opposite the Ox Bow, and the town of Copperfield has been laid out at the mouth of the Pine river. This new town is about six miles above Homestead. Townsite companies have been formed, and a town located on nearly every piece of land between Huntington and Ballard's Landing. The terminus of the railroad, at least for a time, will be at Homestead.—— It is proposed to build a railroad from Baker City, down Powder river, to intersect the Snake River railroad. The right-of-way is owned by W. L. Vinson, and last fall the people of Baker City subscribed $100,000 to start this line, and this subscription is yet available. Vinson is now in Boston trying to secure additional aid, and a recent telegram from him states that he has succeeded. This diagonal railroad will pass through the mining districts east of Baker City, from the Flagstaff to the Timber Canyon mine, and tap the copper belt at a point south of Sparta.—— An association is being formed in Baker City to promote the development of this mining district, and already 100 of the mining, business, and professional men have joined and pledged their support.

Baker City, April 20.

SOUTH DAKOTA.

CUSTER COUNTY.

(Special Correspondence).—The industry around which all interests cluster in the Black Hills is mining for gold, but there are many other minerals found here. Among these are the lithia-bearing ores, some of which are being mined and shipped, partly to New Jersey, and partly to Europe. One of these mines, belonging to W. R. Bond, is situated about seven miles southeast from Custer, and the owner has a contract to furnish ore on board cars here at $25 per ton. Another is the Etta mine, which yields amblygonite that is shipped to the Standard Essence Co., at Trenton, New Jersey. This mine, which belongs to the Harney Peak Mining Co., was the scene of the first discovery of tin in the Black Hills in 1882. A. M. Lane is the superintendent.——The mineral wolframite is in demand and is found in many mines in Custer county, and to some extent in Pennington county. This ore is found in the granite, in pockets, and in the old micacious slates; the veins, although regular in the slates, are never large, and are seldom wider than three feet.——There is no copper produced in the southern hills at this time, although there are many prospects which have excellent showings; these for the most part are in limestone, and the ore occurs in pockets. One carload from the Southern Queen ran 52% copper.——A good deal of mica is being mined in this district. The New York and the White Spar are yielding about 5,000 lb. per day of merchantable mica, which is worked up by the Westinghouse Electric Manufacturing Co. at its factory at Custer.——The Saginaw Mining Co. has ceased work in the drift on the 400-ft. level, and the men are getting out logs, and running the sawmill, preparatory to building a quartz mill, which will be of 100 tons capacity, with a cyanide annex. I. W. Herber is the manager of the mine, which is situated eight miles northeast from Custer, in what is known as the Penobscot mining district. Herman Ratte, manager of the Ivanhoe group of mines, is in

the East, where he will meet the stockholders and plan to erect a mill. This property is situated about eight miles northeast of Custer.

Custer, April 27.

LAWRENCE COUNTY.

Reports from Lead state that the waters of Whitewood creek have been turned into the workings at the 300-ft. level of the Homestake mine, to extinguish the fire which has been burning for four weeks. It is expected to take 30 days to flood the mine to the level and 60 days to clear the workings of water after the fire is out. For the next 30 days there will be a complete shut-down in all departments. The loss to the company, already, is estimated at $1,000,000, and will be double that before the mine is again in working order.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The smelter of the Keller & Indiana Smelting Co., at Keller, dependant for coke on a 26-mile wagon haul in addition to railway transportation, will probably not be in operation until a railway is built from Republic, 50 miles down the Sans Poil valley, to Keller.——A contract has been let for the first 200 ft. of the lower adit on the Gwinn mine.—— The employees of the Mineral Hill M. & T. Co., operating near Danville, have struck for eight, in place of ten-hour shifts, complaining also that the ground at and near the face of the adit, now in 800 ft., is soft and liable to cave. The company pays $3.50 per day for miners, which is satisfactory. The adit is to be driven 2,500 ft. to the vein.

Republic, April 26.

OKANOGAN COUNTY.

(Special Correspondence).—The discovery of a copper deposit in the lower adit of the Favorite mine is reported at a depth of 200 ft. The ore previously developed is silver-lead, in a quartz gangue.—— Strong indications of a pay-shoot are reported from the Little Chapaca mine. Charles A. Andrus, the manager, is talking of using power, in place of hand-drills, as soon as the Similkameen Falls Power & Development Co. can furnish electric power.—— The levels of the Ruby mine, at the base of Mt. Chopaca, are all connected, ready for stoping as soon as the Vancouver, Victoria & Eastern railway is completed to the mine.—— The lower adit of the Mountain Sheep mine, in over 1,000 ft., has intersected two veins. Drifts are being driven on one, which is 18 ft. wide, in hope of striking a pay-shoot. The vein material in both drifts is low in grade.—— At the Copper World Extension mine, 125 ft. back from the breast, on the 300-ft. level, a drift west from the cross-cut has developed a lens of ore carrying pyrite, gold, and copper, four feet wide. The company has since ordered the drills removed to the 200-ft. level, where a lens of ore 20 ft. wide has been stripped for 20 ft. on the hanging-wall side to prepare for stoping.—— A strike of gold-copper ore is reported at the end of a 250-ft. cross-cut, on the Andy Starr group. The vein is three feet, and the rich streak is from four to eight inches wide. The claims are southeast of Loomis. Another discovery of ore, near Crumb's farm, on Douglas Mtn., is reported rich in gold, silver, and copper. Several claims have been located.—— A large interest in the Trinity G. & S. M. Co. has been sold to C. Johns, of Chicago, and the working force will be increased from five to 17 men. The company will have electric service from the Similkameen Falls P. & D. Co. The Trinity mine, six miles from Orrville, is expected to be put on the shipping list. A wagon-road will be built from it over a mile, to the V. V. & E. railway. The president of the company is Edward Davis, of Spokane, the principal place of business.—— The Plant & Callahan Mining Co., with James T. Plant, G. W. Newbert, Henry Rines, and C. E. Williams, of Mora, Minn., G. P. Ward, of Alexander, Minn., S. Callahan, of Spokane, and P. Connelly, of Somas, Wash., as trustees, has been organized with a nominal capital of $1,250,000. This company has purchased the Anaconda group of four claims in Conconnulli district, near the old Ruby camp; $40,000 is reported to have been paid for the claims, which are traversed by two veins, bearing silver and copper. Sixteen years ago, report says, $10,000 worth of ore was shipped from a streak discovered in a 150-ft. adit, which assayed from $1,200 to $1,500 per ton in silver, and 2% copper. The largest vein, about 25 ft. wide, yields ore assaying from $20 to $50 per ton. Both veins are expected to be cut by a new adit, one at 400 and the other 600 ft. in from the portal.—— At the Mineral Hill mine, near Conconnulli, driving will be started at once on two veins, cut by an adit now in 1,840 ft., and the adit will be driven to intersect another vein, which is thought to be about 350 ft. farther in. This expectation is based on the relative position of the croppings. The intention is to strike the largest vein, which is wide, at a depth of 1,000 ft. The silver-lead ore will be sorted and the best grade hauled by wagons to the V. V. & E. railway for transit to the smelters. The Okanogan electric railway will pass near the property when all of the ore, it is said, will pay to ship.—— On Peacock Mtn., about three miles south of Conconnulli, the Salmon River Mining Co. owns a large group of claims, traversed by several veins. Large bodies of copper ore have been developed by surface workings. Under the direction of William McDaniel the company is starting an adit to penetrate the mountain 3,000 ft., and develop the property at a depth of about 1,500 ft. below the surface. The site selected is close to the survey for the Okanogan electric railway. It is planned to install a compressor during the summer.

Republic, April 26.

BRITISH COLUMBIA.

The strike of the coal miners has had a very depressing effect on mining activity, owing to the uncertainty of the situation, and the knowledge that if the strike should last long enough, all the smelters and mines would have to close down indefinitely. The ore shipped and crushed at the Rossland mines for the week ending April 20 was as follows: Centre Star, 1,440; Le Roi, 2,205; Le Roi No. 2, 490; White Bear, 105. Total, 4,240 tons of ore for the week.—— The contract for the main shaft at Le Roi is finished, and another contract will be let as soon as the cross-cut is made at the 1,650-ft. point to connect with the winze workings. West of the Big Josie dike, work is being pushed and it is expected that some large bodies of good ore will be developed in this part of the workings. There are about 1,000 tons of coal at the mine, and shipments will be continued as long as the railroads will accept them.——At the Trail smelter of the Consolidated company, there were received 5,152 tons of ore during the week. Besides the ore from the Rossland camp, other shipments to this plant were as follows: From Snowshoe, Phœnix, 1,499 tons; Silver King, Nelson, 645; Victoria, 80; St. Eugene, Moyie, 354; Strathmore, 31; Sunset, 31; La Plata, Kokanee creek, 46; Last Chance, 22; Duncan, 21; and American Boy, 21.——To the Northport smelter, 2,320 tons were shipped during the week from Le Roi. Two furnaces were kept in operation.

The Boundary shipments were as follows: To Granby smelter, from Granby mines, 19,686 tons; from Emma, 200. To British Columbia Copper Co.'s plant, from Mother Lode, 5,320 tons of ore; from Emma, 40; from Snowshoe, 1,200; and from Morrison, 150. To Dominion Copper Co.'s smelter, from Brooklyn, 1,440 tons; Rawhide, 1,760; Idaho, 384; Sunset, 736; Mountain Rose, 140. To Trail smelter, from Snowshoe, 760 tons; Providence, 80; Strathmore, 20. To Nelson smelter, from Emma, 30 tons. Total ore shipments for the week, 31,946 tons. The Boundary smelters treated ore as follows: Granby smelter, 19,209 tons; B. C. smelter, 9,847; Dominion smelter, 4,460. Total treatment for the week, 33,516 tons.

MEXICO.

SONORA.

The new No. 2 furnace has just been completed at Cananea. Work on 3 and 4 will be started at once. No. 1 furnace has been handling more than 400 tons per day since it was blown in. All four of the new furnaces will be in operation by June. Two new converter-stands and eight new shells have been ordered, although the converting capacity is now in excess of the matte-producing capacity of the plant.

Special Correspondence.

Chihuahua, Mexico.

The Palmilla Gets New Machinery.—Oil Process at the San Francisco del Oro.—Unwatering the Iguana.—Electric Street-railway for Parral.—Sale of Mines.—New Enterprises.—News of Mining Activity.

The famous Palmilla mine of the Parral district has recently installed three Gould duplex motor-driven geared sinker-pumps, with motors of 30, 20, and 15 h.p.; one Gould triplex geared double-plunger station pump, driven by a 150-h.p. induction motor, capacity 500 gal. per min. under an 800-ft. head. This station pump is installed at the 620-ft. level. It will increase the capacity of the pumping machinery to 1,100 gal. per min. The machinery was sold and installed by Braniff & Co., Mexican agents for the Westinghouse Co.——The aerial tramway, connecting the San Juan shaft of the Palmilla mine with the *patio* of the agency of the Monterey smelter No. 2 at Parral, is expected to be in operation in May. This is a single-cable tram with 100-kilo buckets, driven by a 15-h.p. electric motor. The towers are built of steel and the installation is well done. The capacity of the tram is said to be 100 tons per day, it was made by the Ropeways, Ltd., of England, installed by Luis Monroy Duran & Co., of Mexico City.——A 50-ton testing plant, which is in itself a complete mill, is being installed at the mines of the San Francisco del Oro, situated in the Santa Barbara district. This plant is expected to be in operation by August, and will consist of Sutton-Steele dry tables, and the Mineral Separation Co.'s oil process. If this experimental plant proves a success on this ore, a 300-ton plant will be built. Mr. Hyslop, the general manager for the company, says that this process has been worked successfully on a large scale by the Mineral Separation Co. in England, and that tests have been carried out thoroughly on this ore, but his company has determined to put up this testing plant before building the large mill, thus proving the test on a large scale. The San Francisco del Oro is now shipping approximately 50 tons per day, but expects to increase this to 100 or 125 tons in May. Mr. Hyslop states that the mines have taken out 70,000 tons of ore in the course of development, and 325,000 tons are blocked out in the mine. The development work is being pushed as fast as possible.

The American Zinc Extraction Co. has recently installed at their Tajo mine, in the Parral district, two new 80-h.p. boilers, completing their battery of 360 h.p. A new Wellman-Seaver-Morgan Co. double-drum hoist has been installed at the main shaft, together with a new head-frame, ore-bins, tramways, etc. Underground, a new duplex Prescott sinker is holding the water at the 200-ft. level. The mine is now one of the steady shippers of the district, and Mr. Swain, the manager, says that the shipments will be increased and the development work pushed.——The Benito Juarez Mining & Land Co., which recently purchased the Benito Juarez mine in the Parral district, is developing this property as fast as possible, under the management of D. F. Riddell. The shaft has been sunk to the 180-ft. level, and at this level they have a 150-ft. drift to the south. The company now has its own assay plant, and is erecting the necessary buildings at the mine for the accommodation of the machinery. A new 30-h.p. Weber gasoline engine has recently been installed.——The Iguana Mining Co., under the management of A. R. Grigsby, is now unwatering the Iguana shaft, having recently installed a new 80-h.p. boiler, giving a boiler capacity of 120 h.p., and a new 200-gal. Wilson-Snyder sinking pump. As soon as this shaft is unwatered, they will cross-cut to the vein at the 200-ft. level, and continue sinking the shaft to the 500-ft. level.——The new milling and cyanide plant of El Rayo Co. is expected to be in operation in May.——A contract has been awarded McQuatters & Trueheart for the construction of an electric street-railway in the city of Parral. This road will be approximately 4½ km., and will operate, beside the passenger cars, platform-cars for handling freight from the station of the Mexican Central and the Parral & Durango railroads to the city. The new company is known as the Urban Rural & Mining R. R. Company.

The Los Muertos mine, on the Veta Colorada, under the management of Floyd R. Thompson, has increased its production since the first of the year from 800 to 2,000 tons per month. Mr. Thompson reports that he has opened up some good orebodies recently, but at the present time is paying more attention to the development than the production. He also states that they are contemplating the erection of a large mill to treat the low-grade ore.——The Clarinas mine, in the Santa Barbara district, and the adjoining claims called the Reforma group, which was recently sold by Grant Gillette to Howell Hines and associates, will soon be equipped with four new hoists, air-drills, and the necessary machinery for the full development of these properties. A railroad switch will be laid to connect these properties with the Mexican Central at Santa Barbara station. Power for the operation of the machinery will be purchased from the Tecolotes plant.——T. C. Williams, of the Hidalgo M. & M. Co., operating the Delfina mine in the Cienega de Olivos district, reports conditions favorable at that property. The company has just made a shipment of ore running 24% copper, and 600 to 700 gm. silver per ton.

Butler and Cooper, who are now working the Perros Bravos properties of the Pittsburgh Mining Co., at Santa Barbara, have taken options on the San Rafael, La Cabriza, Las Auris, La Quroa, and Los Pinos properties, belonging to the same company. They will start development work at once.——The Guadalupe mine, owned by Vicente Visconti, of Santa Rosalia, and situated in the eastern part of the Parral district, has recently been examined by Mr. Harris, engineer of the American Smelters Securities Co. This is a copper property with some ore blocked out.——The foundations and buildings for the new power-plant at the Capuzaya mine are completed. The machinery is said to be on the way. The electrical part of the equipment is Westinghouse. Work has been suspended at the mine until the power-plant is completed.——The 3,000-h.p. gas power-plant of the Minas Tecolotes y Anexas at Santa Barbara has been completed. The new machinery consists of Loomis-Pettibone gas producers and Crosby engines, with double acting units.——The Buen Viento mine in the Parral district, owned by the Buen Viento Mining Co., is replacing the gasoline hoist with an electric hoist in order to hasten the development of this property. C. F. Gerhardt has charge of this work.——The Esmeralda group of mines in the Parral district is now under examination by Philadelphia people.

The Americana mine in the Terazas district, now being operated by a Boston company, has three large pumps in operation unwatering the mine. George Boyce is the manager.——The Madronas property in the Santa Barbara district is being worked by J. F. Johnson, of Parral. Good ore has been reported in the bottom of the shaft. ——The spur connecting the Cigarrero mine in the Almoloya district with Baca station on the Mexican Central railroad is expected to be completed early in May. ——The new owners of the Central Lucia mine in the

Chorreros district expect to equip this property with new machinery throughout, the old machinery being in bad condition. This property was recently sold by Mr. Hathaway.——G. A. Burr has formed a new company of Philadelphia people to take over the Los Mechos property, which lies north of Indé. The new company is called the Los Mechos Mining & Smelting Co.——A. Spencer Crago, of the Gladys Proprietary, Ltd., reports a rich strike at El Bronce mine in the Roncesvalles district. Mr. Crago has been sinking here for twelve months, and is now down 230 ft. vertically, and in good ore.

The new machine shop of the Parral Power Reduction Co. is already crowded with work. At the present time they are overhauling and reconstructing two engines of the Mexican Central railroad. The new foundry is completed and will be blown in at once. The power-plant is in operation, supplying power to the district.——The approximate production of Parral for March, as given by the *Parral Miner*, was 21,567 tons, disposed of as follows: Shipped to smelters, 10,242 tons, locally treated, 11,325 tons.——The Prieta mine at Parral is to resume operations in the near future. New machinery is reported to be on the road, the electrical part of which is furnished by the General Electric Company.

Cobalt, Ontario.

Railroad Facilities.—Prospectors Are Active.—The Temagami Reserve.—Output of Mines for First Quarter.

The Government railroad that affords entrance to Cobalt and other mining camps of northern New Ontario has, in connection with the Grand Trunk railway, inaugurated a new service between Toronto and Cobalt. The distance by rail is 330 miles, and leaving Toronto at 9 P. M. the train arrives at Cobalt at 8:15 the following morning. This gives the visitor an opportunity to spend the day in the camp and return to Toronto by the 8 o'clock train the same evening. Two Pullman cars and one first and one second-class car make up the train, and the indications are that a third Pullman will have to be added shortly.

In the woods there is still two or three feet of snow, but bare spots are appearing on the hill-tops and in the clearings. The rivers and lakes are still frozen over and hurried and sometimes desperate efforts are being made to transport supplies up to the more northern points before the ice breaks up. It was feared two weeks ago that the ice on the Montreal river was breaking up, and as high as $130 was paid per team for a trip that occupied three days. Parties taking in supplies to Larder lake were charged even more than that, and Robert Tighe was asked $800 for transportation of a gasoline launch 20 miles. He, however, was an old campaigner, having had experience in both commissary and transportation departments in South Africa and British Columbia, so he took charge of the undertaking himself. As a result, his launch is now on the frozen banks of Larder lake awaiting the opening of navigation.

The district north of Latchford in the townships of James, Smythe, Tudhope, Barber, and the great Temagami Reserve are attracting many prospectors. This Reserve is owned by the Province of Ontario and comprises 100 square miles. It was originally set apart as a great timber reserve and a special permit is required to prospect. Fire rangers are on the look-out and demand production of a permit from everyone on the ground.

The output of Cobalt proper for the first three months of the present year has been encouraging. The bad roads and the installation of new plants have been responsible for some delays in the case of new shippers and the non-appearance of some of the regular shippers. Cobalt's output for the first quarter has been 2,898 tons, or an average per working day of 37 tons. This will be equally divided between first and second-grade ore. The Nipissing leads the list with 817 tons; then the O'Brien with 639 tons. The Buffalo comes third with 302; then the Tretheway with 216, and its next-door neighbor, the Coniagas, with 206 tons. La Rose shipped 187 and the Silver Queen 110 tons. The Tretheway made no shipment during January, being engaged in the installation of plant, and, for a similar reason and the absence of power, the Coniagas was closed down for one month.

The mining tax bill has been passed by the Ontario Legislature without any essential change in its details. It provides for a tax of 3% on all profits of mines over $10,000 a year, and an average tax of two cents per acre

on all mineral lands in inorganized districts. The lands in organized municipalities being already liable to assessment for municipal taxation. Another measure affecting mineral lands was introduced, dealing with a large class of holdings in the settled districts in which the surface rights only of the land have been sold, reserving the mineral. The latter when undeveloped, has escaped taxation, all local taxes being levied on the owner of the surface. An amendment to the law was introduced making the mineral rights assessable. This was regarded as too sweeping, and likely to discourage investment, and was subsequently modified so as to make it applicable only to "petroleum rights" in place of "mineral rights" generally, in which form it was finally adopted.

Another important measure passed was one introduced by the Government guaranteeing the titles of the purchasers of the mining rights to the beds of Cobalt lake and Kerr lake, which were purchased from the Government for $1,085,000, and $178,500, respectively. An action brought by the Florence Mining Co. against the Cobalt Lake Mining Co. disputing their title on the ground of a statutory right created by prior discovery, is now pending. The bill was keenly opposed, and amend-

ments were introduced to the effect that the rival claimants should be given an opportunnity to make good their claims in court, and should secure compensation if successful in doing so, but these were defeated, and the bill passed as it stood.

The owners of La Rose mine have filed a claim against the Government for the whole of the royalties collected from the output of the O'Brien mine, amounting in all to some $54,406 up to date, being 25% of the value of the ore mined. They make this demand on the ground that when the Government brought suit against the O'Briens at the instance of La Rose interests, who claimed the location as bona fide discoverers, the suit was subsequently compromised on the agreement of the O'Briens to pay the Government a royalty, and the claim of La Rose owners were ignored. These cases illustrate the uncertainty and confusion still prevailing in the matter of titles to mining locations, and are hardly calculated to reassure investors as to the security offered by an ordinary title.

Denver, Colorado.

Conference of Governors.—Cyanidation at Cripple Creek.—Use of Water-Power.—Copper Resources.

The Governor of Colorado has lately issued an invitation to the governors of 15 States to join in a conference upon the best methods of securing the development of the West. This is as it should be. Co-operation is the first requirement for the attaining of large results, and it is to be hoped that this conference of executives may meet, and see its way clear toward bringing about some substantial progress in the upbuilding of the West. And in this connection mention should be made of the meetings of the Irrigation Congress and of the Mining Congress, which have served to draw the men of similar interests together for the exchange of ideas, the stimulus of mutual effort, and the greater achievement of co-operation.

The ways of the promoter are many and devious. One of his lures is a diagrammatic sketch showing a projected tunnel boring its way through the face of nature, under hill and dale, cutting in its course anywhere from five to a hundred veins that extend down to the everlasting depths; carefully omitting to state that these veins, if they ever are cut, are more than likely to be represented by a barely discernible crack, an unmineralized zone of fissuring, or a vein that, though mineralized, is too low-grade to work. But photography can also be bent to meet the schemer's purpose. A recent advertisement shows what purports to be a huge dump, indicating the enormous amount of development work done. The photographer, by the aid of an imperfectly aplanatic lens, and by getting downhill from the dump, is enabled to make a few tons of rock loom up in a way that is familiar to every beginner with the camera, who has forgotten to remove the feet of his subject from the foreground. Such methods savor so strongly of dishonesty as to deserve the hearty condemnation of all mining men.

Recent progress at Cripple Creek includes the starting of the construction of a 1,500-ft. dam to impound the tailing from the mill of the United States Refining & Reduction Co. The new tailing-plant of the Portland Gold Mining Co. is in full operation, and yielding satisfactory results. The new mill of the Golden Cycle Mining & Milling Co. expects to be handling 800 tons per day within the next month. The four new Edwards roasting furnaces installed by this company have made a satisfactory showing in a preliminary run. The Consolidated Copper Creek Co. is considering the erection of a cyanide mill at the mine, and there is thus a notable number of cyanide mills already in operation or nearing completion. The dividends paid by Cripple Creek companies during April amount to $256,627; among the mines paying dividends are the Portland, Vindicator, Mary McKinney, and Elkton.

The utilization of water-power to generate electricity and the transmission of the latter a long distance to supply the needs of towns, mines, and reduction works has progressed wonderfully in recent years in Colorado. Many plants are already in operation, and within the last year at least three more large new companies have been chartered. One of these is in Gore cañon, and the other two are on the Grand and Taylor rivers, respectively. On the Arkansas river, in Chaffee county, a low head is being utilized in connection with the new smelter in course of construction there. This is expected to have a capacity of 300 tons daily, and is to use a patent process known as the Kuenzel, a feature of which is the use of oil as a fuel. It is claimed that the company will be able to smelt its ores at a cost of 45 cents per ton—whereat the old smelterman smiles and says nothing.

The development of the copper resources of the Front range has been the subject of a recent talk by R. A. Trevarthen. Mr. Trevarthen observes, with a good deal of point, that there are copper veins in the Front range that are quite as good as many of those found in other more remote districts now being boomed. When strawberries are ripe, prunes receive little attention, though welcomed in the winter. Similarly, low-grade copper deposits that could be worked on an adequate scale at a substantial profit are likely to receive little attention when occurring in proximity to larger and more valuable deposits of gold and silver, though if situated in a region not so enriched by the precious metals they would be regarded as possessing great possibilities.

Butte, Montana.

Production of Copper in April.—A Decrease.—Affairs of the Raven.—United Copper and Heinze.—Vein in the Amazon-Butte.—Colusa-Leonard Extension.—Butte & Bacorn.—Successful Explorations.

The copper production of the Butte mines in April was 27,673,200 lb., or 3,000,000 less than in March. The mines of the Boston & Montana Co. were closed for a little while on account of labor troubles. The ore mined and copper produced by the different companies during the month were as follows:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana	99,000	7,227,000
Anaconda	114,750	7,512,000
Butte & Boston	14,400	936,000
Washoe	11,700	737,100
Parrot	9,000	558,000
Trenton	11,400	695,400
North Butte	40,500	3,645,000
Coalition	42,750	3,035,250
Origiual	27,000	1,728,000
East Butte	4,500	360,000
Pittsburgh & Montana	6,900	538,200
La France	6,000	420,000
Miscellaneous	3,750	281,250
Total	391,650	27,673,200

The daily average output of ore by all the mines was 13,055 tons, and the daily average copper production was 947,440 pounds.

There is much doubt as to the ability of the Raven company to acquire the interests of the Amalgamated and Trenton companies in the Snoozer and Old Glory lode-claims, though an agreement has been reached with J. B. Leggatt for the purchase of his interest in the Old Glory, amounting to seven-twelfths. Without the Amalgamated interest in the property the Raven would have little use for the Old Glory, as for the Snoozer,

since the Butte Coalition Co. owns an interest just large enough to prevent the Raven company from operating the property whenever it chooses. Stockholders of the Raven have been hopeful that for the good of all concerned the Amalgamated and Coalition companies might be induced to part with their interests. Negotiations have been under way for some time, but with no success up to date. It is possible that some understanding will have been arrived at by the time the special meeting of Raven stockholders is held in Butte on May 15, when it will be decided if the capital stock is to be increased from 500,000 to 1,000,000 shares.

During the recent investigation of United Copper affairs through court proceedings in New Jersey, persons formerly identified with Amalgamated and Coalition testified that the total price paid United Copper for its Butte interests was $10,500,000, but Heinze interests claim the price was in excess of that figure. United Copper officials have declined to give a list of the company's present holdings, on the theory that such publicity would defeat negotiations for the acquisition of other property and interests. It has generally been understood that United Copper owns the La France Co. which is operating the Lexington mines in Butte, and that the Heinze interest in the Davis-Daly Co. is an asset of the United Copper, but that is not certain. It is pretty well understood, however, that United Copper owns properties in Montana, Idaho, Washington, Utah, Arizona, and Mexico, and probably some in British Columbia. F. A. Heinze, since the sale of his Butte properties to the Butte Coalition, has been active in the search for new properties for the United Copper to take the place of those sold, and his friends say he has been successful, and now controls a lot of dividend-paying mines.

A vein of 7% copper ore, four feet wide, has been cut in the shaft of the Amazon-Butte, one of the new companies operating on the east side of the district. A portion of the vein is sulphide and carries high-grade ore. The shaft is 360 ft. deep. The officials of the company feel confident that it is a persistent vein and that it will be found large and full of ore a few hundred feet deeper. A station will be cut at 400 ft., and some cross-cutting will be done at that level. The Amazon-Butte lies south of the Bullwhacker, from which tributers are shipping 100 tons of ore daily. The Bullwhacker, however, is a north and south fault-vein, and the ore is regarded by some mining men as a 'blow out,' while the Amazon-Butte is on east and west veins, the characteristics of which are identical with the big permanent lode of the Butte district.

The Colusa-Leonard Extension Co. is cutting a station at 600 ft. and it is now the intention of the company to do some exploration work at that level. It is believed that a vein, from which some fine looking stringers have been cut in the shaft, will be found a short distance to the south.——The Belinda shaft of the Butte & Bacorn Co. is 850 ft. deep, where a station is being cut and a pump will be installed. No other work will be done there, but the shaft will be carried down to at least 1,000 ft. The shaft of the Calumet, which is not far from that of the Belinda, is down about 830 ft. Some big veins have been opened in both mines, but at the depths where the work has been done they do not carry commercial ore. The fact that the veins become more highly mineralized in depth is satisfactory evidence to manager Bacorn that it is only a matter of sufficient sinking when the company will have productive mines.——Twenty inches of copper glance and three feet of ore carrying from 7 to 10% copper has been encountered in the Alex Scott mine by the Butte-Montana Co. It was found in a raise on the 600-ft. level about 135 ft. east of the shaft. The Alex Scott shaft, with three compartments, has been completed to a depth of 900 ft., where a station is being cut. When this is completed, sinking will be resumed, and the shaft taken to a depth of at least 1,200 feet.

Salt Lake, Utah.

Transfer of Annie Laurie.—Shipments From Tintic.—Uncle Sam Finds Ore.—The Emma Re-opened.—Annual Report of Daly-Judge.—Railroad to Pioche.

The Annie Laurie mine and several adjoining properties in the Gold Mountain district have passed into the control of Albert Carr and associates, of New York. It will be operated hereafter under the name of the Gold Mountain Consolidated Mining Co. It is the intention of the owners to erect a new mill to treat from 500 to 1,000 tons of ore daily. The company controls 2,500 acres.

The management of the Utah Copper Co. has the first unit of its new concentrating mill at Garfield ready for operation. It is anticipated that the start will be made not later than May 15.—— The Bingham Amalgamated Copper Co. is said to have secured options on the Tiwaukee and Congor groups, situated near the Copper Glance possession of that corporation.

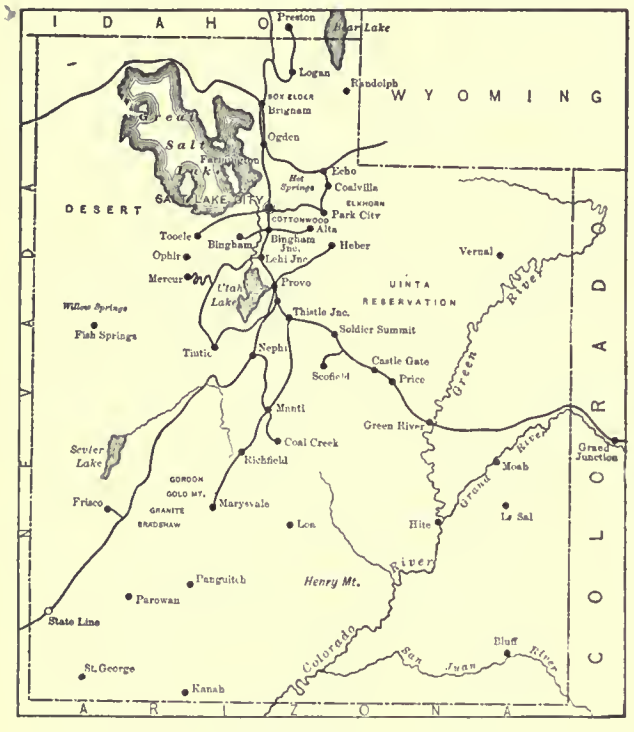
The ore shipments from the Tintic mining district last week amounted to 163 carloads, the shipping mines and respective amounts being: Ajax, 4; Beck Tunnel, 12; Bullion Beck, 6; Carisa, 5; Centennial-Eureka, 51; Colorado, 6; Eureka Hill, 2; Eagle & Blue Bell, 5; Gemini, 5; Godiva, 4; Grand Central, 6; Lower Mammoth, 7; Mammoth, 18; May Day, 2; Ridge & Valley, 3; Scranton, 6; Shoebridge Bonanza, 2; Tintic Iron, 4; Uncle Sam Con., 4; Victoria, 3; Yankee Con., 8 carloads.—— The Uncle Sam Con. Mining Co., has found a large body of ore in a cross-cut from the bottom of a shaft sunk 250 ft. below the Humbug adit. The strike is considered to be most important, and caused a strong upward movement in the stock. The Colorado Mining Co. is driving for an orebody on the 300-ft. level. Shipments have been resumed from this property after a temporary cessation due to the bad condition of roads.—— Negotiations are still pending for a consolidation of the May Day and Uncle Sam mines at Tintic.

The famous old Emma mine, in the Alta district, has recently been acquired by Jesse Knight and associates, of Provo, Utah.—— The Cliff Mining Co., at Ophir, in Tooele county, owner of the Buckhorn mine, after a long period of preparation, has begun to produce regularly. The new aerial tramway is in commission and handling 50 tons of ore daily. Several new mine-buildings have been erected, and physical conditions underground are said to be most satisfactory.—— The Independence Gold Mining Co., operating at Gold Springs, in Iron county, has purchased property between its own domain and that of the Jennie Gold Mining Co., and will push development.

The annual report of the Daly-Judge Mining Co., operating at Park City, has been issued. At the beginning of last year the company had an indebtedness of $230,976, represented in $209,000 worth of outstanding bonds, and an overdraft at the bank of $21,976. This debt was entirely discharged, and at the close of the year the treasury contained a balance of $269,038; the net earnings for the year being $500,015, or 61.2% of the gross earnings. A total of 63,322 tons of ore was mined, 13,011 tons being of shipping grade. The mill treated 58,845 tons, from which was obtained 9,838 tons of lead concentrate, and 8,320 tons of iron and zinc middling, showing one ton of concentrate produced from each 3.2 tons of crude ore. The mill handled an average of 165 tons per day. Owing to the impoverishment of the ore-

body on the 1,500-ft. level, the production of crude ore has been reduced, and consequently there has been a falling off in the earnings. About 2,000 ft. of development was done in the mine during the year. The total production since the incorporation of the company has been 1,068,346 oz. silver, 3,544 oz. gold, 28,961,777 lb. lead, 12,188,260 lb. zinc, 156,110 lb. copper, which sold for $1,279,076.

The construction of the railroad into Pioche from Caliente, Nevada, is being pushed ahead rapidly, and the camp of Pioche is taking on a lively appearance. Mine operators are preparing to work their properties upon a large scale. Among the number will be the Ohio-Kentucky Mining Co., and the Phœnix Reduction Co., both of which are controlled by Salt Lake parties. A



Utah.

compressor plant has been ordered for these mines. E. L. Godbe, of Salt Lake, is manager.

London.

Cornish Mining.—Operations at Dolcoath.—Reopening of Old Mines.—Mt. Boppy Gold Mine.—Returns From the Indian Mines.—Satisfactory Yields.

As regards production, no marked improvement is visible in Cornish mining during the first quarter of the new year, although there is promise for the near future in the properties that have been taken in hand by Cornish Consols and its allied companies. This group of financiers is not responsible for the operations at Dolcoath, except as owners of the 'dues.' In that respect, probably from the point of view of the executive, the transfer of the mineral rights has not had the effect of facilitating the rapid development of the premier mine on the scale hoped for. It is rumored that the price named by the new landlords at which the dues might be compounded by the mine was £250,000 while the directors offered £80,000. Until this bargain is concluded or definitely off Dolcoath may be expected to show a masterly inactivity, nursing its resources for independent action when the circumstances become more propitious. The wisdom of this policy depends on the price of tin, and in some quarters where foreknowledge of the course of the markets may well be looked for, the certainty of the continuance of the present value of the metal is considered as by no means assured. For the first 12 weeks of the year, from January 1 to March 23, inclusive, 355½ tons of block tin and 28½ tons of slime were sold by Dolcoath at average prices respectively of £120 19s. 8d. and £89 6s. 3d. per ton, the total realized having been £45,656. The quantity of ore crushed during this period was 25,637¾ tons. Compared with the corresponding period of last year the returns of black tin show a falling off of about 23 tons, but there is an increase of total value of £4,700, due solely to the rise in tin. The report for March from Carn Brea & Tincroft is described as showing some improvement compared with that of the previous month, but the continued breakdowns in the pumping and other plant of these mines point to the necessity for a thorough overhauling of that department. Judging from the tone of the proceedings at the statutory meeting of the Cornish Development Co., the outlook for the stockholders appears to be hopeful. This company is allied with Cornish Consols in the working of South Crofty, and the directors expect dividends on their investment in that mine up to 100% by next year. Another property in which this company is jointly interested with Cornish Consols and one or two other newly formed groups, is the Wheal Sisters, a group of four mines in the neighborhood of St. Ives. Those four mines returned large tonnages of tin down to the time when they ceased working from the fall in the price of metal and from lack of working capital. The companies interested, which are all strong, with ample funds, are joining together to unwater the mine and bring it to a producing stage, with a view, either of retaining it for dividend purposes themselves or floating it off into a separate company as may appear best later on. They have agreed to put up £20,000 for the purpose of unwatering, and are prepared to provide a further £20,000 when it is required. The engines for unwatering this mine have been on order for some time, and should be delivered by the end of June. The order for these engines was in the shape of two units of gas-suction engines of 150 h.p. each. The order went to the British Westinghouse Co., together with the order for the necessary dynamos and electrical equipment.

Mount Boppy now holds the proud position of being the premier gold producer in the State of New South Wales. At the eighth general meeting of the company this week it was stated that the milling capacity has been augmented to the extent of over 60%, which has given an increase of ore milled exceeding 21,000 tons. The percentage of gold extraction from the residues has improved beyond previous records, with excellent prospects of doing still better. The production has increased over that of the previous year by nearly £10,000. The reserves of ore, which last year were 182,000 tons, now stand at 191,000 tons, notwithstanding that 72,976 tons have been extracted from the mine, and have passed through the mill during the past twelve months. The sales of gold for the past year amounted to £126,229 and the gross receipts to £127,261, as compared with £116,870 for the preceding year. The working costs and total expenditure in Australia and England amounted to £64,134, which left a profit of £63,127, against £65,172 the previous year. The difference of £2,045 in favor of 1905 is accounted for by the fact that 21,098 tons of ore were milled in 1906 in excess of 1905, which, while increasing the aggregate milling cost, produced nearly £10,000 worth more gold. The superintendent has pursued the policy recommended by Mr. William Frecheville of working, with his rich reserves, a larger proportion of the lower-grade ore in the mine, in order to ensure the even continuity of its life. Mr. Frank Taylor, of John Taylor & Sons, in the course of his address said that early in August they received the welcome news

that, in addition to the rich ore which had already been developed at the 400-ft. level, the deepest in the mine, a new orebody of great width and richness had been discovered at about 800 ft. south of the main shaft. Since then this new discovery has opened up remarkably well, developing a valuable addition to the reserves. Besides this there are other important and successful developments proceeding at this level, which encourage the management to look forward to finding rich ore when the vein is explored at greater depth and also westward. The developments at this level continue good, and sinking below it is to be commenced.

The Indian returns for last month from the mines under the management of John Taylor & Sons are regarded as satisfactory. The Mysore production of 17,376 oz. (which includes 480 oz. obtained from steaming the plates) compares with 16,122 oz. in February. Although the destruction of a portion of the dressing floors by fire recently has necessitated a temporary reduction in the tonnage treated, by milling quartz of slightly higher grade than usual, the output has been well maintained. Champion Reef produced 10,607 oz. last month, as against 10,236 oz. in February, but the ore milled was increased by 1,070 tons. During the four months from October 1 to January 31 60,766 tons of quartz were crushed and 80,980 tons of tailing treated by cyanide, for a total yield of 45,687 oz. of gold worth £173,537. For the corresponding period last year, the output from 78,260 tons crushed and 67,743 tons cyanided was 70,617 oz. gold worth £270,435. Nundydroog last month yielded 6,146 oz., or 310 oz. more than in February, and improvements are also shown by Ooregum, which produced 5,642 oz., as compared with 5,584 oz. in February, and by Balaghat, whose output was 3,132 oz. as against 3,074 oz. in the previous month. A cablegram from Dharwar Reefs gives the result of the first crushing, exclusive of the cyanide return, as 510 oz. from 1,494 tons crushed, or an average of about 7 dwt. per ton. The assay-value of the tailing is 4 dwt. 5 gr. per ton, of which it is probable nearly 4 dwt. can be extracted. This would be equal to a yield of about 11 dwt. from both sources.

Johannesburg, Transvaal.

Political Conditions.—Disappointment Over the New Government's Attitude.—Labor Conditions.—Mining Outlook Distinctly Bad.—Withdrawal of Capital From the Rand.—A Locust Storm.

At a banquet given in Pretoria to General Botha and the members of his ministry, the Premier made a speech that has encouraged people to hope that a way would be found out of our difficulties, both industrial and political. That was nearly a fortnight ago. Today the feeling of despondency has re-asserted itself, after the first brief session of the Transvaal parliament. The whole mining community awaited with keenest interest the pronouncement of the Government upon the question of unskilled labor. The speech from the Throne dealt with the question in a very vague way. It was stated that the Chinese would be sent out of the country as soon as possible. Sir George Farrar, the leader of the opposition, endeavored to force the Government into an avowal of a definite policy, and one of the Progressive members tried to get a commission appointed to enquire into the question of the unskilled labor supply. But the Government used its big majority to squash all discussion on the one question that is agitating everyone.

We are now in a quandary. Parliament does not meet again until the middle of June. The first batch of Chinese finish their contracts in June. These coolies will have to leave the country. Before the end of the year there will be 20,000 time-expired Chinese. It will be impossible to fill their places with Kaffirs.

It looks as if the policy of the Boer Government is to be one of drifting. They will utter nebulous platitudes about the necessity of supplying the mines with unskilled labor, but do nothing. As the contracts of the coolies run out, they will allow them to go back to China. It matters not to them if some of the mines close down, or if the others work half-time. In fact, this is the declared policy of their leader, who on many occasions has stated that it is far better to make the mines last two hundred years than to work them out in fifty years.

In face of this policy of Het Volk, it is ridiculous to look for any big expansion in the Transvaal. Contraction seems almost inevitable. It is highly probable that the zenith of the Rand has been reached, and that the future will be humdrum. The eventual closing down of some of the poorer mines, say in the next couple of years, seems inevitable. The distress in our midst will not grow less. It is to be hoped that other countries will follow Australia's example, for she has helped her stranded citizens to get back to their native land.

Capitalists who for years have confined their attention to the Rand, are beginning to tire of the uncertainty here, and are quietly sending their engineers to other countries, South America, Mexico, and the United States, to spy out those lands. Until the labor question is settled once and for all, and settled satisfactorily, it is a great mistake for investors to put their money into Rand ventures.

There has been any amount of grumbling on the part of the public, over the municipal power-station. This is the largest station in the world using producer-gas entirely, for generating power. The number of breakdowns has been appalling. The whole electric tram-system is sometimes hung up for hours, and as this generally happens on Saturday nights when there is the greatest traffic, there is much inconvenience. Producer-gas engines have not been a success here. This failure teaches the old lesson, so necessary in mining, to be careful how you adopt new methods. Better pay a bit more and be sure of your power. This experiment has cost the community thousands of pounds.

One of the worst locust storms recorded in the history of the Transvaal swarmed over the city and mines a day or so ago. The invaders carried everything green before them. Stretches of green veldt were wiped out in a night and next day the color was a brown, as if winter had come suddenly. At nights the locusts piled up on the railroad tracks, and great inconvenience was caused. So slippery did the wheels become that sand was thrown on the rails. Most of the trains have been arriving late. It seems incredible that such insignificant invaders as locusts should cause such havoc, but when one is told that the cloud was over twenty miles long and eight miles wide, it is seen that the pest has done the damage by sheer weight of numbers. The market gardens in many sections have been completely ruined. A small field of corn belonging to the writer was wiped out by the invaders in one day, and men who have toiled for weeks in gardens looked on in despair to see their labor destroyed in a few hours. This storm is moving steadily northward, and will destroy the promising crops that this year's fine rains have made possible. And yet, you will hear people spout about the agricultural possibilities of the Transvaal, whereas it is one of the most accursed countries from the agriculturist's point of view in the world! "It's an ill wind that blows nobody any good." The Kaffirs have caught sacks of locusts, and are having feasts. Unfortunately there is no wild honey to go with the locusts. The Chinese also have remembered how they eat these insects in their native land, and they also have gathered bushels of manna—I mean locusts.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

VIRGINIA has been the most prominent producer of manganese ores in the United States, and with but six exceptions has ranked first for the last 26 years.

A BY-PRODUCT in the manufacture of zinc from ores obtained in northern New Jersey containing iron and manganese is used in the production of spiegeleisen.

THE best locality in the United States for making tests on the raw materials used in cement manufacture is at Allentown, Penn. The Lehigh Testing Laboratory is specially equipped to do such work well.

THE tantalum minerals are in demand on account of their containing the metal tantalum, which is used at the present time only in the manufacture of very fine wire for use in the construction of what is known as the tantalum lamp.

ELECTROLYTIC ZINC is made by Brunner, Mond & Co. Their product is real electrolytic zinc, being deposited by electrolysis from a zinc solution, and is a high grade of metal. Zinc is also made in Sweden and Norway by electro-thermic smelting by the De Laval process. Beer, Sondheimer & Co. are the agents in America.

THE approximate method given in the American Ephemeris & National Almanac for determining latitude from altitudes of Polaris at any hour-angle will give the latitude within a few tenths of a minute of arc. The maximum error will rarely exceed half a minute. The tables given in connection with this method are based on constant values of the right ascension and declination of Polaris and no account is taken of the change of apparent place of Polaris from day to day.

THE greatest demand for arsenic is from manufacturers of paris green, which is an aceto-arsenite of copper, worth 12c. per lb. at New York. It is used as a pigment, and its poisonous character, while restricting its employment for this purpose, makes it an admirable insecticide in agriculture. It has been often suggested that the silver-lead smelters and refiners who produce appreciable quantities of copper sulphate and can recover arsenic in roasting speiss, should undertake the manufacture of paris green.

FEW MINERALS are more universally distributed than the micas, but this wide distribution pertains only to the mineral in flakes and crystals too small to be of value. Both biotite and muscovite occur in igneous and metamorphic rocks, as well as in the sediments derived from the crystalline rocks. Phlogopite appears to be confined to the metamorphic rocks, and generally with relations indicating its igneous origin. Muscovite is the mica mined in the United States and India, while phlogopite is obtained from the Canadian mines.

THE most important manganese-ore-producing country is the Russian Empire, the major portion coming from the Caucasus district, where these ores occur as bedded deposits, lying almost horizontally near the tops of the lofty hills, at an altitude of 1,000 ft. above the Kvrilli river. The existing beds, as opened on seven mountains near the village of Chiaturi, are reported to have an average thickness of six to seven feet. The ore is chiefly pyrolusite, but other oxides of manganese also occur. It is claimed that an area of more than 22 square miles of the present surface is underlain by ore available for mining. In some localities the materials composing the bed, without sorting or cleaning, carry 50% of manganese, the average being probably 40 to 45 per cent.

LAND below the line of ordinary high tide is not 'public land.' If the tidal water forms a State boundary the land belongs to the State. If it bounds a Territory the land is reserved for the use of a future State. No location of a lode-claim can lawfully extend below the line of ordinary high tide. Under special congressional laws placer mining is permissible between the low and mean tides on the shores of Behring Sea under such regulations as may be prescribed by the Secretary of War. This is the only privilege sanctioned by the Federal Government, of carrying on mining operations below the line of ordinary high tide, of which we are aware.

THE 'law of the apex' embraces all deposits in place within boundaries that are definable. The definition of the word 'vein' as used in the United States mining laws is broad enough to include mineralized masses, veins of replacement and of impregnation, as well as fissure-veins. The existence of 'walls' is a non-essential. The commercial limit of mineralization is a boundary in the legal sense. The deposit described in the inquiry is a 'vein' within the meaning of the Federal mining laws. Its boundaries might be either the lime as a foot and shale as a hanging wall, or the lime as a foot-wall and the limit of commercial ore as the hanging. The law does not take into account the geological origin of the deposit. If in place, mineralized and lying within boundaries that may be ascertained, it is a vein.

THE decrease in the quantity of quicksilver produced in California is due rather to a lessened production of all the mines than to any serious falling off in the output of any single one, with the exception, perhaps, of the New Almaden property in Santa Clara county. This is the oldest quicksilver mine in the country, and for years was the largest producer on this continent. The place that it held in the production of quicksilver is best indicated by the fact that of the total output of the whole State of California during the last 55 years nearly 2,000,000 flasks, fully one-half, has been produced by the New Almaden. At present the New Idria mine in San Benito county is one of the largest producers in the State. The Napa Consolidated, in Napa county, and the New Almaden come next as regards output. The Oceanic, the Great Western, the Great Eastern, the Socrates, the Karl, and the Altoona have been the other principal producing mines of the State.

UPON application for patent the re-locator or his successors in title will not be permitted to include in his estimate of the value of improvements required by law to be made as a condition precedent to patent, any of the labor done or improvements made by the original locator. A voluntary grant from the original locator to one who has perfected a valid re-location is ineffective for this purpose. *A fortiori*, a grant from the purchaser at a sheriff's sale made prior to the re-location would be of no avail. Expenditures for patent purposes must have been made subsequent to the re-location by the re-locator or his grantees.

It is doubtful whether core-drilling can be considered as an expenditure applicable to patenting. This question has never been decided by the Land Department or the Courts. In our opinion this is not such an expenditure or improvement as will satisfy the law. It does not facilitate the extraction of ore. It may indicate where the ore is or is not, but possesses no other permanent value.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

On Knocking.

The Editor:

Sir—In the boom mining camps of Nevada, particularly, one is apt to see a card stuck up in some bank or office which is addressed to anyone who reads, giving him this homely advice:

"Do not be a knocker. Put up your little hammer. There is no end of fun in minding your own business, *et cetera.*"

This, translated, means that if you are not taken in, do not interfere with the good work of taking others in. In all these camps there are several good mines, perhaps as many more promising prospects, twice as many more on which work is suspended indefinitely, a number of prospects being worked with more or less vigor, but all of doubtful issue, and a thousand claims taken up for several miles in all directions, that legally could not be held, for no metal-bearing rock can be shown on any of them, though they all have the regulation 10-ft. hole sunk, even in 'drift,' solid rock not being encountered. In one camp they claim to have no failures, still there are a number of equipped shafts that are not working nor have they been for some time past. However, there is always some excuse. One, for instance, is shut down because the president of the company died.

There is a fixed equation for all mining successes, and it is:

A lode + pay ore = Results.

It is bad enough to have to prospect for pay-ore in a promising lode and "results" are often doubtful in the finest of veins, if there is no shoot of pay-ore. How much more doubtful must "results" be when the prospecting work is confined to hunting for a vein. Seeking "results" under the last conditions (sinking blindly in country rock and driving in search of a vein) is analogous to looking for that needle in the hay-stack. And still this is what is being done continually in the Nevada camps, and companies are formed to 'make' a mine on the conditions just outlined. Some of these companies do honest work, even if they are failures. Others do more or less work, the promoters holding the managing positions and drawing salaries. Others are swindles pure and simple, the only beneficiaries being the promoters.

When glowing accounts are given of what some other mines in the district are doing or have done, and stock is offered "for a limited time," of course, at 10 or 15c. per share, the investor of small means had better leave it alone.

One property I call to mind bases its claims to future greatness on the fact of being on a line drawn between two producers two miles apart. The attention of the public is always called to note the proximity of the property promoted to some producing mine; often, regardless of its location in regard to the same. Others will gloat over the fact that they are on the extension of some big mine, regardless of what the distance may be.

Few people take into account that a fissure seldom is continuous for a thousand feet, and that 400 ft. is a generous length, on the average, for a good ore-shoot. If getting into line with some known orebody a mile away will produce "results," regardless of the lack of vein or orebody, or even indications of it, can be taken as "convincing evidence that the work will develop a great producer," why stop there? Why not follow up the good thing on the same line right on around the world? One proposition is as sane (or, rather, insane) as the other.

Prospective buyers should be careful, and always submit prospectuses to some mining man, even if they have to pay him for the advice given. It will, as a rule, be the cheaper way in the long run. They should recognize the responsibility an engineer assumes in giving such an opinion, and he should be paid for it. I once tried to dissuade a man from spending money on some claims that offered no inducement at all, as far as I could see, for developing them. I noticed he did not take the advice in good part, and tried to sustain his action by saying he had found carbonate ore carrying 70% copper. When I remonstrated, saying there was no such copper content in carbonate ores, he replied: "I see you don't know as much about copper as you think you do." I guess he was right, as I took the reply to mean, mind your own business; and emphasized the slogan of his district: "Don't be a knocker."

Knocking is as essential to the true advancement of a camp as promiscuous booming; for a judicious amount of truth does no harm except to the man with the gold brick, and all right-minded men should be ready to squelch him, and his schemes, if necessary.

All of the camps referred to offer good opportunities, but many shady ones are offered on the strength of the few good. These are usually colored in the highest degree, and are to be shunned. The man with ordinary mining experience can easily size up the fakes, and those outside of the charmed circle should consult with men they know have the experience, before investing. This, as a rule, would be the safe way; but many like to take the 'flyer' on their own hook; and these, usually, are able to stand the loss. The majority, people of small means, invest hard earned savings with the hope of making something more, and it is a sad fact that these are usually fleeced. This class of people is the great mine that the promoter exploits, and it is no wonder that he tries to appeal to the false pride of those of us who represent capital and investors seeking legitimate business ventures, by the insidious threat (more than appeal), "Don't be a knocker;" meaning, if not taken in yourself, don't interfere with others biting.

Have investors no rights that can command respect? Because we who may represent large investors are not taken in, shall we stand passively by and see the small man 'done up,' just for fear we may be called 'knockers?' Certain kinds of knocking are to be frowned down. But if disclosing the nefarious schemes of unscrupulous promoters, for robbing the poor man and woman of their small savings, so that these latter may beware; or, if turning down the parasite who seeks you to introduce you to some property owner, and then demands a commission from you, in case a deal is made, is called knocking, then I say knock and knock hard, for moral and civic decency demand it.

Well directed exploratory work is to be commended, for mines are *made*, as a rule; but there must be a fighting chance. When one sees shafts sunk in barren country rock (lava, at that), and where this juts up through the overlying drift, because it is decomposed and stained with iron oxide, it is pointed to as "the mother lode," it is liable to bring on a tired feeling; and when one sees work prosecuted where the outcome is certain failure, and knows that many a poor man's *all* is being engulfed, it makes him weary indeed; but, when he sees other, supposed, work purely on paper, and the pictured results solely imaginary, then the tired feeling vanishes and the desire to knock is hard to resist. Then it is justifiable, and the harder it is done the better; for such promoting is done to mine the pocket of the investor. The

looking out for the investor's interests is *our* business, and "there is no end of fun minding your own business."

E. A. H. TAYS.

Phœnix, Arizona, March 27.

Slime Filters.

The Editor:

Sir—I have read with great interest the contributions to your columns regarding recent developments in slime filtering. The rivalry of the adherents of the two most prominent systems of vacuum-filtering should tend to improve the practice, but I have watched in vain for a comparison of the results attained here with those reported of the Ridgway filter at the Great Boulder mine.

The question at issue between the Butters-Cassel and Moore adherents seems to be as to whether it is more economical to install and operate a plant designed to transfer solutions to stationary filters or to transfer the filters (and charge) to and from the solution. As there seems to be little evidence to support the claims of superiority in the matter of attendance or speed of deposit and washing the cake, in the same slime, the discussion might be said to be narrowed to the comparative cost per ton-capacity of a plant of each type capable of conducting the remaining operations, transferring, and discharging, in a fixed time, with the question of comparative maintenance costs as a further determining factor. Are there not questions of more vital importance to the development of the art?

Judging from published reports on Moore and Butters-Cassel installations, it apears that 50 sq. ft. of filter-area per ton of slime (dry weight) treated in 24 hours is well below the average required. The Ridgway filter, with a total effective filter-area of 50 sq. ft., is reported to have a capacity of from 25 to 50 tons per 24 hours, varying with the character of the slime, or one to two square feet per ton of slime treated. This comparison is rather startling and suggests the necessity of a careful examination of the fundamental elements of the two plans of operation. No conceivable difference in slimes could account for such a wide divergence of results.

In the American practice a cake three-fourths to one inch thick is formed on perpendicular canvas filters. In the Ridgway machine a cake from three-sixteenths to three-eighths of an inch is formed and suspended on a horizontal filter-cloth. The vacuum applied is about the same, but while the cake is formed in 13 seconds in the Ridgway machine, from 30 to 60 minutes is required in the American plant. From the nature of the operation it is evident that the rate of accumulation of slime becomes slower as the thickness of the cake increases. The first one-eighth inch is deposited in a much shorter period than the last eighth. It is improbable that the American filters accumulate from three-sixteenths to three-eighths of an inch of cake in the first 13 seconds, but the long time required for transfers makes a thick cake a necessary evil.

The very rapid accumulation of the Ridgway filters must be due to elementary differences that would not appear of such importance. Is it the difference in the filtering medium or the position of the filter? It seems likely that filter-cloth is so much less easily clogged than canvas, that the main difference in results is accounted for by this structural difference alone.

The results of observations on the rate of accumulation of the progressive layers of the cake, the effect of position, horizontally suspended or vertical, the rates of accumulation on canvas and filter-cloth, and the durability of filter-cloth in horizontal and vertical positions, would be of great assistance in improving our practice. Progress in the direction of a compact automatic plant that can be installed and maintained cheaply. The last word has not been spoken in the field of vacuum-filtering.

Pockets in Gold Veins.

The Editor:

Sir—In explanation of the occurrence of pockets in the upper portion of gold veins as presented by George W. Kimble in the issue of March 16, I offer a theory in opposition to that of secondary enrichment by descending solutions. It is as follows: The pockets are due to the precipitation of gold from the ascending metalliferous hot spring waters at the points of *sudden* dilution, cooling, and mechanical interference by descending surface waters.

This theory is based on the occurrence in Nova Scotia of rich gold-bearing quartz at the intersection of small lateral, locally termed 'angular,' veins with the main quartz body, and is consistent with the facts as observed by Mr. Kimble at Thompson's mountain, in Eldorado county, California.

The term 'ascending hot spring waters,' borrowed from W. H. Weed, is preferred to 'magmatic waters,' or 'waters ascending from the depths.' 'Magmatic waters' seems to exclude the ore-bearing solution arising from sedimentary rocks, while 'waters ascending from the depths' is a term suggesting the 'barysphere.' Mr. Kimble seems inclined to believe in a descending gold solution, from which the metal is precipitated through the agency of pyrite or the products of its oxidation, while I take the view that the gold and associated iron bodies described were simultaneously present in ascending solutions, but were precipitated at different points. The nature, or chemical composition of ascending metalliferous hot spring waters has never been satisfactorily explained. I have a working theory on the subject, but like Thomas Lawson with his remedy, it will be produced later.

In Nova Scotia, gold occurs in addition to the instances mentioned, in the locally named 'rolls' and 'barrels,' which have been frequently described. In these cases the gold appears to have been precipitated by a shattered condition of one or both vein-walls producing a mechanical interference with the ascending solution at various points, as well as offering a greater cooling surface. Secondary enrichment in some cases offers a problem similar to that of 'the apple within the dumpling.'

Assay of Cyanide Solutions.

The Editor:

Sir—I have noticed in the PRESS of March 5, Mr. Gendar's scheme for the assay of cyanide solutions.

I would call the attention of those interested to the following well-known method, which, for rapid work and accurate results, will, I think, be found to compare favorably with any.

Measure, according to grade of solution, a convenient quantity of KCy (working solution), add concentrated sulphuric acid to excess; let stand two minutes; then add from ½ to 1 gram of cement copper and boil until the solution takes on a blue or greenish-blue color, pour onto filter-paper in funnel, wash twice with boiling water; dry the filter-paper containing the precipitate in air bath or otherwise; flux filter-paper and precipitate in assay-crucible, or, scorify, cupel, part, and weigh.

The Great Gold Mines.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

It is always interesting to be told what are the biggest things of their kind and those who operate mines will be glad to know to what heights of productiveness their properties may attain, if all goes well. In sifting the data available concerning the leading gold mines of the world, we find sixteen that are worthy of being placed in one group, representing the great bonanzas of the present day. The selection of these leaves room for discussion. It is our opinion that a great mine must not only make a big output but must make it regularly and with a prospect of continuance. Stability is essential to greatness, for the less a mine is a mere incident in gambling and the more it approximates the ideal of an industrial undertaking the greater it is—at least, from the standpoint taken for this tabulation. Another group of notable mines will be described in a later article, and among them will be several famous properties that may be deemed by some to belong to the first class.

THE GREAT GOLD MINES.

The figures given represent the output for two consecutive months, either November or December, 1906, or December, 1906, and January, 1907. It is not practicable to quote later months, because it takes time to collect, and then to sift, the data. By giving the figures for two months, instead of one only, it is possible to note a variation, which in some cases is a characteristic feature. The best mines are the most regular, the regularity in many instances being secured by the use of a reserve of gold, the amount of which is now made public both in Western Australia and on the Rand. In one or two cases the profit for the month is estimated from the total profit officially given for a period of six months or a year. Wherever the figures are estimated they are marked with a star. In bringing everything to a uniform basis, the pound sterling is taken at $4.85 and the ounce of fine gold at $20.67.

Among the sixteen, five mines belong to the Rand. This is a fair proportion, having regard to the leading position of the Transvaal as a gold-producing country. The Simmer & Jack has 360 stamps, of which 320 are maintained in operation; this mine is estimated to have 11,000,000 tons of ore available; the Robinson has 210 stamps and its reserves are expected to last twelve years; the Robinson Deep supplies 300 stamps and has 10,500,000 tons of ore blocked out; the Village Main Reef has 220 stamps, as also the Cason. The monthly production of these big mines on the Rand is so regular that the yearly output is fairly indicated. Next on the list comes the Esperanza, one of the lucky purchases of the Guggenheims, who control it. This mine is at El Oro, in the State of Mexico, about 90 miles from the City of Mexico. During 1906 the Esperanza produced 159,047 tons, yielding $4,548,975, out of which $3,420,462 was paid in dividends. But the reserves are only estimated at $1,500,000, although cash on hand and ore in transit make a sum of $3,709,226. Operations have been crippled for several months by shortage of railroad cars, for most of the ore goes to the smelters. The total production of the Esperanza has been 32,500,000 *pesos*, say $16,000,000. Of the Homestake mine it can be said that it has been the pride of American mining men for twenty years on account of the small cost of operating and the big profit won from low-grade ore. Monthly statements are not made, so that those we give are estimated from the official report for the second half of 1906, which states that 720,216 tons were crushed for a yield of $2,791,215 and a profit of $797,534. Another American mine is the Camp Bird, near Ouray, in Colorado. The contrast is vivid, for the Camp Bird is a high-grade mine with high costs and small reserves, as compared to the Homestake. At the present time the Camp Bird

mills are treating ore above the average of the mine, it being the policy of the management to make large profits in compensation for a period of unproductiveness due to the destruction of the mill, by snowslide and fire, a year ago. Ordinarily the Camp Bird makes a monthly profit of $100,000 to $125,000, and the ore averages $25 to $30 per ton. In the four years ending September 30, 1906, this mine yielded $8,152,000, of which £676,000, or 82½% on the capital, was distributed in dividends. As there was a balance of £115,000 on hand, making 12½% more, the total profit since 1902 was £791,000 or nearly four million dollars, equivalent to 95% of the capital of the company. The mine carries a large tonnage of broken ore in the stopes, which is valued at $2,600,000 and is held in reserve. The total reserves are estimated at $4,500,000.

Two Indian mines come next. In India there are eight gold mines of importance and all of them are in the Kolar district of Mysore. The three leaders are the Mysore, Champion Reef, and Ooregum, which yield an average of 18,000, 11,200, and 5,500 ounces of gold monthly. In the year ending September 30, 1906, the Champion Reef produced 203,174 tons yielding 177,641 oz., worth £678,706. From this a profit of £347,609 was made, that is, $1,685,903. During the past year the 210 stamps of the Mysore mine treated 185,900 tons of ore, yielding 205,918 oz., worth £809,413, giving a profit of £460,014, equivalent to $2,231,068. The reserves of ore amount to 747,000 tons, equivalent to four years' supply. The deepest workings are at 3,500 ft., on the dip of the vein. The dividends to date are $23,402,300 on a capital of $1,479,250 or £305,000.

Four great mines are credited to Western Australia; all of them are at Kalgoorlie. The famous Lake View Consols is not included, for it has lost its premier position, although in 1899 it was the largest producing gold mine in the world, yielding 33,160 oz. in the month of May and 199,230 oz. valued at $3,897,479 during that year. The Oroya-Brownhill is the most profitable of the four quoted, but its future is uncertain; in fact, most of the big Kalgoorlie mines have passed their zenith, the lowest levels being less rich than the upper ground. The Great Boulder has 453,000 tons in reserve and is 2,000 ft. deep. The profit last year was £320,258, or $1,553,251. The Oroya-Brownhill paid dividends amounting to £360,000 and the Ivanhoe paid £340,000 in 1906.

In Australasia, outside of Western Australia, there are two truly great gold mines, namely, the Mt. Morgan and the Waihi. The Mt. Morgan, in Queensland, reached its maximum output long ago, in the year ending November 30, 1889, when it produced 75,415 tons, yielding 323,543 oz., worth £1,331,485, while the expenditure was £227,770, permitting the payment of £1,100,000 or $5,335,000 in dividends. The yield per ton was 4 oz. 6 dwt. 4 gr., while the cost represented only 17% of the value of the ore mined in that year. That was a great record. For the half-year ending November 30, 1906, the total revenue was $2,173,482, the resulting profit being $841,260. During the six months the chlorination works yielded 51,878 ounces of gold and 20,838 oz. additional were extracted from the blister copper. Of copper, there were 1,751 tons of blister and 172 tons of precipitate. These metallic products were the yield from 152,678 tons of ore. Thus it is evident that the Mt. Morgan is equally a gold and a copper mine. The output for 1906 was worth $3,778,926. The total production to the end of 1906 has been $2,966,032 tons of ore, yielding 3,079,695 ounces of gold, worth $60,964,087, the total dividends being $32,757,705.

The Waihi is still a young mine, with promise of growth. It is barely 1,000 ft. deep and is credited with reserves of a million tons of ore. Up to the end of 1905 the production had been $21,891,450, giving $9,920,505 in profit. In 1905 the output was 298,531 tons, yielding $3,533,326, and a profit of $1,679,206. In 1906 the Waihi produced 328,860 tons of ore, yielding gold worth $4,001,250. Up to March 1, 1907, the output has been $26,555,690 and the dividends $11,775,290.

The column giving the value of the ore per ton affords some suggestive variations; it is seen that the richest ore is that of the Esperanza and Camp Bird, and this maximum richness happens to be associated with instability, as an experienced miner would expect, for in both cases the present output is above the average of the mine. Only two other mines, the Mysore and the Oroya-Brownhill, yield ore containing more than an ounce of gold per ton. The poorest ore produced by any really great mine is that of the Homestake, which is the only member of the group that yields an average of less than a quarter of an ounce of gold per ton. Next in lowness of tenor come the Simmer & Jack and Village Main Reef mines, the only ones, except the Homestake, that average less than half an ounce. In regard to the cost, or total expense of mining, hoisting, and then extracting and marketing the precious metals (for there is usually a little silver) in the ore, the figures reflect the relative richness of the material handled, the lowest cost being incurred in connection with the poorest ore, while the highest expenditure characterizes the handling of the richest, as is shown, respectively, by the Homestake and the Esperanza. But low costs are due, in part, to large bodies of ore and the ability therefore to treat an enormous tonnage with a relatively small fixed expenditure. At the same time a low-grade ore is a spur to economical management, which is born of the necessity that is the mother of both invention and resource. However, as the cost of mining is usually at least two-thirds of the total expenditure and as the character of the mining is dependent upon the nature of the lode, it is necessary to refer in detail to this factor.

On the Rand each mine has two, three, and even four seams of hard goldbearing conglomerate, separated by quartzite. The valuable portion occurs in bands from six inches to four or five feet wide, within a width of country varying from 15 to 30 ft., and, to generalize, it may be stated that the average stoping width of ore is from five to seven feet. The dip is flat, to the point of being a drawback. In the Esperanza and Camp Bird the lodes are steeply inclined and about five feet wide, though in both the heart of an orebody will be fully 20 ft. across. The Indian mining companies are working veins from two to seven feet wide, with an average of four feet of quartz, traversing schist. At Kalgoorlie the gold occurs as a tellnride and the stoping width averages six feet of quartz and calcite in chloritic schist. The Kalgoorlie lodes are stoped from two or three feet to 20 or 30 ft., the maximum being in the middle of a lens. In the Lake View Consols the great orebody was 30 ft. wide for a length of 1,000 ft. In the Oroya the stopes average seven feet and the bonanza ore is sometimes 60 ft. wide. The Waihi, Mt. Morgan, and Homestake mines include irregular occurences of ore; the first of these may be described as a lode 100 ft. wide divided by horses of ground, requiring separate stopes; the Mt. Morgan is a highly altered mass of graywacke without definite shape; it is a hill of ore; at 750 ft. below the outcrop the deposit of gold-copper ore covers an area of 1½ acres; the Homestake has an orebody of quartzified schist 400 ft. wide, portions of which are left standing, as much for safety as for economy.

One fact is clear, namely, that in all these great mines the ore is a full stoping width, the economic unit of min-

ing; in none of them is the average less than four feet and in most of them it is five feet or more.

On the whole, we venture to say that the ideal mine is one that has a lode five feet wide, of ore yielding $10 per ton, that can be extracted at a cost of $5 per ton, with reserves of, say, one million tons. And this leads to the question: Which is the greatest gold mine in existence? We hesitate to answer categorically, but we point to three mines any one of which may well be considered first. Those three are the Robinson, the Waihi, and the Homestake. The Robinson has reserves sufficient for a dozen years, that is, 4,500,000 tons of ore. The yield is $14 and the cost is less than $5, so that there is a handsome margin of profit. Only 18% of waste is sorted from the ore as it is broken and the 240 stamps crush at the rate of 5.3 tons per head. The stoping width is 6½ ft. The profits are $3,500,000 per annum. The dividends to date are $25,497,362 on a capital of $13,337,500. The Waihi is a lode averaging 30 ft. of ore in andesite; the best of it has been extracted only to 800 ft., for a length of 2,000 ft., while the shaft is now 1,000 ft. deep. The ore contains a large proportion of silver, but it is readily cyanided. The reserves are estimated at a million tons, but this does not exhaust possibilities or even probabilities; for the property includes a large area as yet not explored in depth. The Robinson, like all South African mines, has a definite end in sight, for the flatly dipping 'reefs' pass into a neighbor's territory and its resources therefore, although tremendous, are limited by known lines. The Waihi and the Homestake can be deepened indefinitely in pursuit of the ore without facing an assured finality. In regard to the Homestake, the reserves are not accurately known, but they are estimated to be sufficient for at least twenty years, that is, over 30,000,000 tons. Dividends to date aggregate $22,134,840. The mine has been worked to about 1,000 ft. and the workings are down to 1,400 ft. But the ore is poor, and despite the exemplary economy exhibited in the operations of this great mine, the margin of profit is so small as to be a factor of danger. So the choice is between the Robinson and the Waihi, and this brings out one of the distinctive features of mining on the Witwatersrand, at least as regards the proved mines that started on the outcrop of the Main Reef series. Most of them have 'deep-level' mines beyond them, that is, where the lode dips out of their territory it is being worked through the deeper vertical shaft of a neighbor in such a way as to afford absolutely reliable evidence as to the richness and width of the ore at the future bottom of the workings of the outcrop mine; in other words, the mass of ore in the outcrop mine has been carefully sampled on a working scale by the operations of the 'deep-level' mine. In this way the width and gold contents of the bottom of the Robinson mine are known, the possibilities of greater richness in depth are absent, but so also are the chances of sudden impoverishment. On the other hand, the Waihi has reserves much smaller, not a quarter those of the Robinson, because it is being developed in the ordinary way, without a deep-level property ahead of it on the dip. Such a mine has chances of striking much richer and even bigger orebodies, but it is also exposed to the risk of disappointments in depth—the pinching of the lode or its sudden impoverishment. For both of these are among the chances of mining. Thus, the Robinson is more nearly an investment, while the Waihi is a most attractive speculation. You choose between the assured prosperity that has a certain and inevitable end in plain sight and the splendid profitableness of a mine having much smaller reserves but the usual uncertainty as to its final performance. As all experience proves that persistence in depth is hazardous and as the bottom of the Robinson's ore measures are known and those of the Waihi are unknown, the choice is between the assured and the possible, where both are sumptuous. We accept the responsibility and label the Robinson as the greatest gold mine in the world, the greatest gold mine ever worked by man.

A Compound Assay-Furnace.

Written for the MINING AND SCIENTIFIC PRESS
By W. J. FLECK.

The improvements of the portable gasoline assay-furnace have caused it to be introduced widely under varying conditions and often the volume of work soon outgrows the capacity and size of the portable furnace. In many cases the assayer does not like to discard it for the larger coke furnace, on account of the costs of fuel, expense of building, dust, and slow heating.

At Fort Bidwell, in California, conditions were all favorable for a compound furnace, two-stage, one using gasoline and the other wood, described herewith:

Gasoline costs 55 cents per gallon, and coke and charcoal are out of the question as the nearest railroad is 100 miles. In our first operations in this locality the gasoline furnace proved to be the best and cheapest; the question was to increase the capacity. This was done three-fold by setting up a large standard charcoal-furnace close beside the small gasoline and firing it with dry wood. The crucibles are charged and placed first in the wood-furnace, where they are annealed and dried and slow fusion begins, thus allowing all gases and traces of moisture to escape. Each crucible is transferred quickly to the small gasoline-furnace which is kept up to a high melting and cupelling heat; quiet fusion begins instantly and in ten minutes the crucibles are usually ready to pour.

With this equipment it is possible to melt and cupel in a single-crucible combination No. 5 Hoskins furnace, 16 assays in four hours, or 50 assays in a No. 6 four-crucible furnace in the same time.

In doing this rapid work, the flux is all first dried in open pans at a temperature of 200° F. before the charge of ore is added. The ore is now intimately ground and mixed with the flux in a small wedgewood, or glass mortar, by using the pestle in one hand for grinding and a small spatula in the other for mixing at the same time. The charge is then placed in the crucible and is ready for the wood furnace. This insures a quick, quiet fusion and the production of a clean homogeneous transparent slag, and the crucible is only slightly attacked on account of the perfect mixture coming in contact with the crucible for a very short time. No excess of flux is used, so the charge is concentrated to the limit of good work.

The old practice of rolling a charge of ore with the flux on a sheet of rubber and pouring lump and fine containing about 3 or 4% water into a crucible, then instantly placing a crucible in a hot furnace is the one most books describe, or in other words, this is about what the obedient student will do. This plan will answer when a large coke-furnace is slowly heated for the first melt, and a large excess of flux and covers are used. It is a well-known fact in chemistry, but not generally known to assayers, that if a sample of gold-quartz is roasted with salt in a muffle, about 50% of the gold will sublime and and escape and is lost as a volatile chloride. This is one of the many reasons why it is best to dry the flux in a large open pan just below the fusing point before mixing with the ore.

This simple elimination of moisture and gases is superior to all the nailed salt covers or any cover or extra blind. Every particle of the finely ground ore should be surrounded with the exact proportions of the fluxing material, all objectionable parts being removed that it is possible to remove before the operation is begun.

The Hercules Mill.

Written for the MINING AND SCIENTIFIC PRESS
By SCOTT TURNER.

The Hercules mill, near Burke, Idaho, is the most recent of the concentrating plants in the Cœur d'Alene region, and is therefore interesting as typifying the most approved lead-silver milling methods in northern Idaho. The mill was first put in operation about twelve months ago, but many changes have been made since that time.

In the original equipment, iron jigs, made by the Hodge Iron Co., of Hancock, Michigan, were installed, but proved unsatisfactory, and were taken out, home-made Harz jigs being substituted. The difficulty with the Hodge jigs was that the screens did not work uniformly, being lively on the outside and dead nearest the plunger, thus making a poor product, and limiting the capacity of the machine. The wooden jigs are working satisfactorily, the equipment consisting of six two-screen, and six three-screen jigs, all screens being two by three feet in area. One of the two-screen jigs is not used at present, being held in reserve, but will probably be used to treat 12 mm. material.

As originally operated, there were no trommels in the mill, all screening being done by impact screens, which, however, proved unsuited for the work, and followed the iron jigs down the hill, a series of trommels taking their place. The principal objection to the impact screens was that they became clogged with wood-pulp. A third departure from regular Cœur d'Alene practice was the installation of large unwatering wheels, for the middling and tailing, which proved troublesome and wasteful of power, and were supplanted by home-made shaking screens.

In fact, every departure from generally accepted practice resulted in failure, with the exception of the Humphrey type of rolls for coarse crushing and re-grinding coarse middling, and the possible exception of the high-speed, narrow-face centrifugal rolls for re-grinding the finer jig middling. The Humphrey rolls have proved satisfactory here, as well as in the new Success mill, where two sets are used for re-grinding, and will probably become a popular type in the region, but the Sturtevant rolls are rather troublesome, due, probably, to the fact that too much is expected of them, as they are running, while set up close, on a feed ranging in size from 20 to 3 mm. and finer, which is too wide a variation for economic work. An easy improvement could be made by running the middling from the third-screen cups of the 20-mm. jigs, back to the Humphrey rolls, for re-grinding with the bull-jig middling. The lateral-adjusting device seems to be the weak part of these Sturtevant rolls.

One marked improvement in the design of this mill is the use of a multiple-unit electric-power system, making it possible, with the well-arranged system of storage-bins, to close down any unit without affecting the remainder, although, of course, the vanners and tables must run if the jigs and Huntington are working.

There is a complete system of electric bells and a code of signals, making it possible to signal the motor-room from any part of the mill. Wires are in place for a system by which it will be possible to stop any motor directly, by pushing a button upon any floor in the mill, thus throwing out the switch at the motor, but this arrangement has never been used.

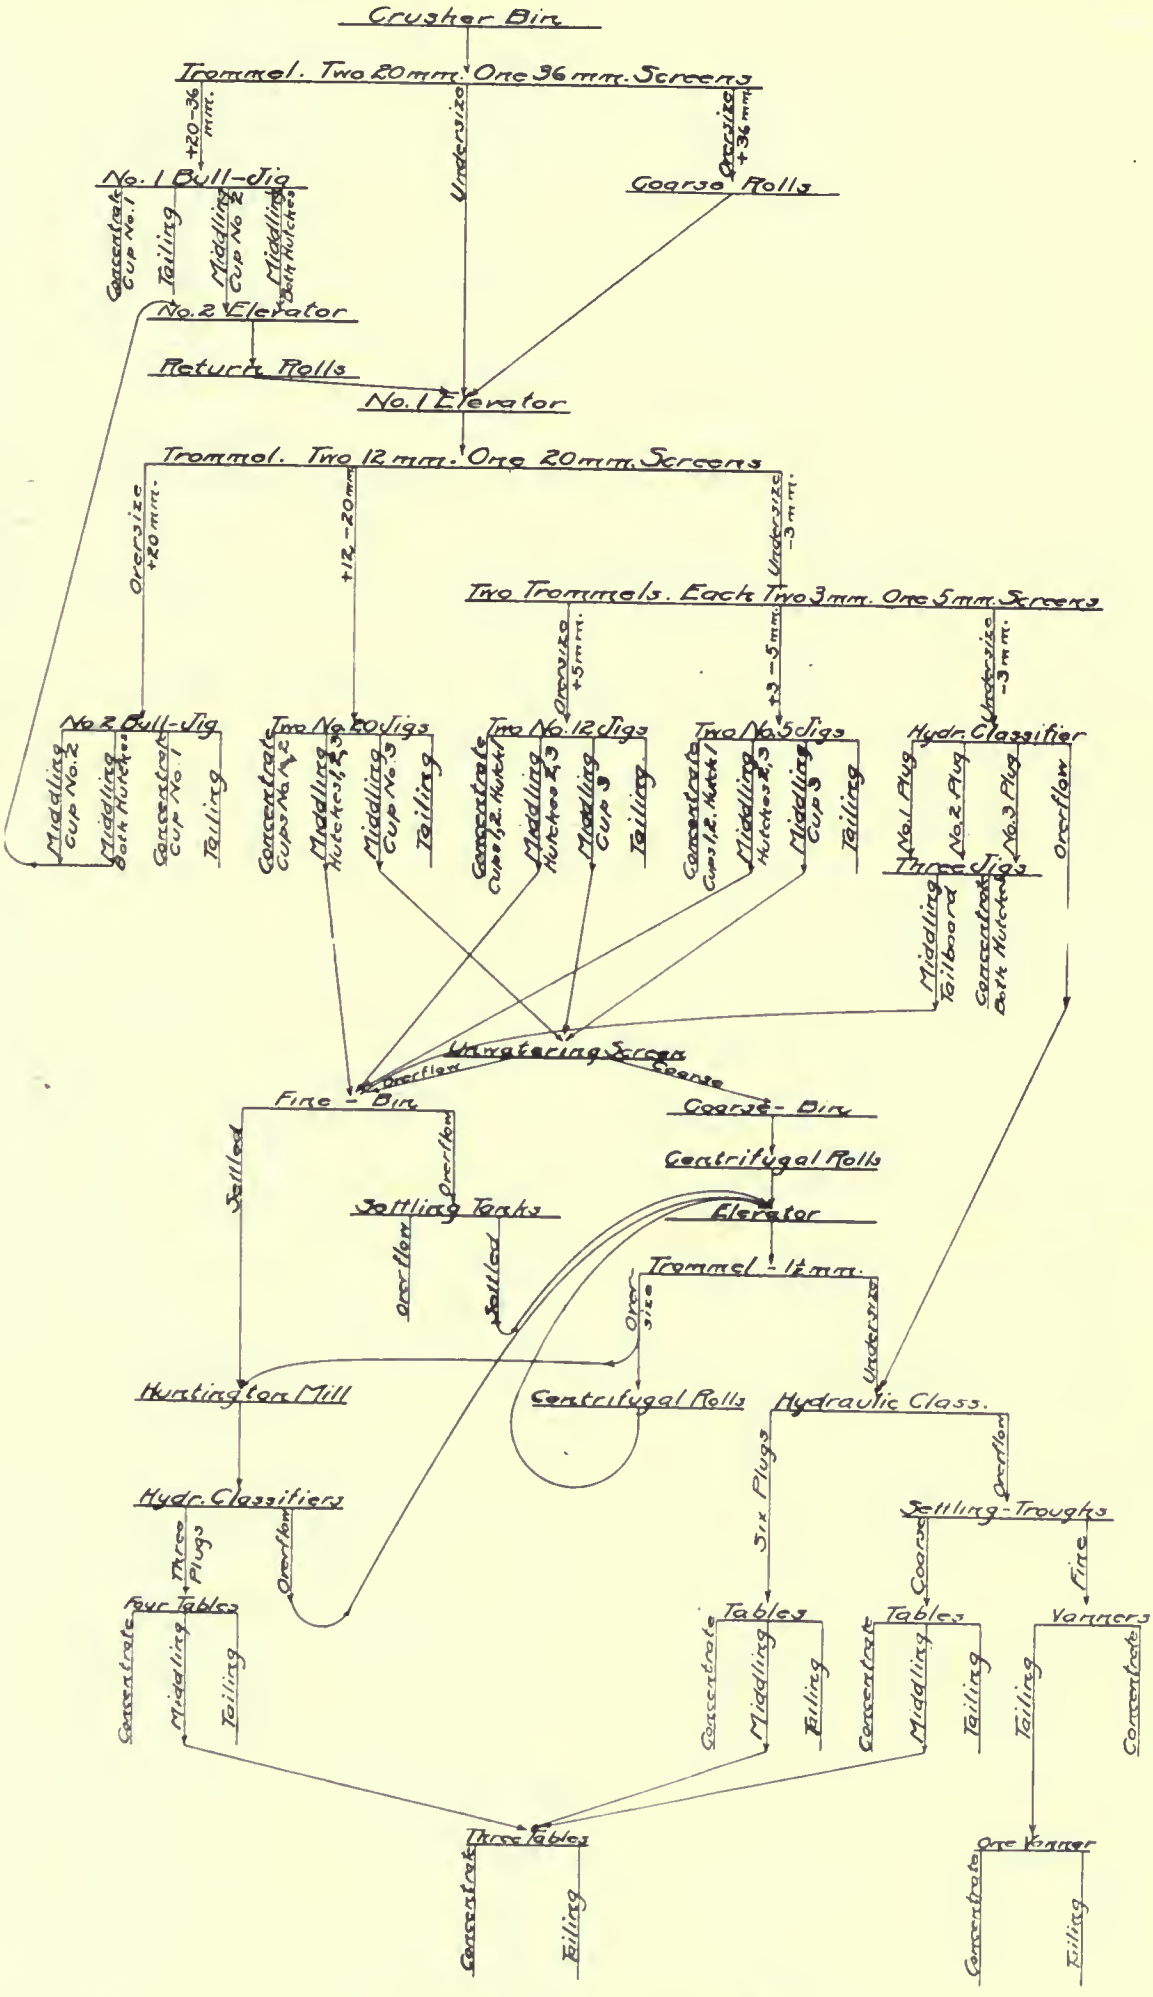
The treatment at the Hercules mill, briefly outlined, consists in preliminary breaking in a Blake crusher, screening, crushing oversize, treatment of screened and classified product on jigs of the Harz type, with subsequent re-grinding of coarse middling from the two bull-jigs in Humphrey rolls and the fine middling in Sturtevant centrifugal rolls, and final grinding in a six-foot Huntington mill. Below the Huntington mill are arranged the Wilfley No. 5 tables, and six-foot Frue vanners, which are fed from classifier and settling-tank plugs. The Wilfley middling is worked over again on a second set of Wilfleys, and the vanner tailing is thickened and treated again on a vanner. Fifteen Wilfley No. 5 tables are used for the first treatment, and five 6-ft. vanners, while three tables treat the Wilfley middling, and one vanner, the vanner tailing.

The mill is built on a steep hillside and but few elevators are necessary, there being an abundance of head-room everywhere in the building, as the total elevation from the track over the upper bin to the lower pump-floor is about 125 feet.

The mill-feed comes from the ore-bins at the mine by an electrically operated surface tram, to a point about 800 ft. above the mill, where it is stored and loaded into three-ton cars on an inclined tram, operating in balance, by which the ore is lowered to the mill, and dumped into the storage-bin, of about 200 tons capacity. The ore is drawn from this bin by a shaking grizzly above the Blake crusher, the fine material dropping through the two-inch holes in the feeder-screen, and the oversize going into the crusher, which is a 12 by 15-in. size; this material is then stored in a bin of about 50 tons capacity. The mill-feed is drawn from this lower bin by a shaking feeder, which is followed by the feed trommel, 9 ft. long and 4 ft. diam., with three screens—two of 20 mm. and one of 36-mm. size. The material finer than 20 mm. goes to the boot of the main elevator, the +20 −36 goes to No. 1 bull-jig, and the oversize to the coarse rolls. The material from the coarse rolls passes to the main elevator, and, together with the re-ground middling of the two bull-jigs and the undersize from the 20-mm. screens of the feed trommel, goes to the main trommel line, which consists of three trommels. The first is 9 ft. long by 4 ft. diam., with one 20-mm. and two 12-mm. screens. The −12 material goes to two small duplicate trommels, the +12 −20 to the pair of No. 20 jigs, and the oversize (+20) to the No. 2 bull-jig. The two smaller trommels are each 7½ ft. long and 3 ft. diam., and are equipped, each with two 3-mm. and one 5-mm. screens. The −3 mm. material goes to the hydraulic classifier of three plugs, the +3 −5 to the No. 5 jigs, and the oversize, + 5 mm. to the No. 12 jigs. Each of the three classifier plugs feeds a two-screen jig, the overflow passing below to the Wilfley-feed classifiers and settling-tanks.

Two storage bins are provided for jig-middling. One bin receives middling from the cup on the third screen of the No. 20, 12, and 5 jigs, after the material has been unwatered. The second bin, for the finer material, gets the hutch-middling product from the 20, 12, and 5-mm. jigs, the material passing over the tail-board of the three classifier-jigs, and the fine material carried by the water in unwatering the coarse middling. This bin overflows into a series of flat settling-tanks, from which the settled material is periodically drawn through plugs in the bottom and run into the elevator leading to the baby-trommel. The overflow from the settling-tank is either pumped back to the jig-floor, or run into the tailrace.

The coarse middling is drawn through gates, from the bin, into the centrifugal rolls by Sturtevant feeders, elevated, and screened in a trommel with a 1¼-mm. screen, and the oversize can either be fed to the second set of rolls, or sent to the Huntington mill, while the undersize goes to the tables. The material from the fine-bin is drawn through plugs direct into the Huntington, and then is classified and goes to the tables. This arrangement often causes trouble, as when a screen breaks on the coarse jigs, coarse material gets into the hutches, passes into



Flow-Sheet of the Hercules Mill.

the fine-bin, and stops the small plugs through which the feed is drawn. This also occurs when the unwatering screens wear through.

On the table-floor the arrangement includes a double row of tables and vanners, there being 15 No. 5 Wilfleys and five 6-ft. Frue vanners. These machines get their feed from various classifier plugs and from plugs in the bottoms of two long double rows of V-shaped settling-tanks, which extend the entire length of the floor, making a settling-tank length of over 500 ft. The tables make three products, namely, concentrate, middling, and tailing. The middling passes to a lower floor where it is treated on three tables, each making concentrate and tailing. The vanners make concentrate and tailing, and the tailing is thickened in a settling-tank below, and drawn through plugs to a vanner that works it over again.

The accompanying table shows the monthly averages, for three months, of the mill-feed, and the tailings and concentrates from the different machines. These results are from roughly-taken hand-samples collected every hour, and while this method is open to criticism and is necessarily inaccurate, still the monthly averages are fairly representative. It seems a pity that some automatic sampling devices are not installed, as there is an abundance of head-room, and they could easily be added at various points. These assay-returns would be more instructive if accompanied by a statement of the approximate weight of each product. The only weighing that is done is on the balanced tramway, where the cars are stopped and carefully weighed on an inclined scale, but no moisture-sample is taken, although there is much variation in the water-content of the ore. The concentrate is weighed when loaded into the ore-wagons from the storage-bins below the mill. The mill is treating approximately 250 tons per 24 hours, and is shipping nearly 40 tons of concentrate per day, averaging between 50 and 60% lead and 50 oz. silver, making a gross output of about $125 per hour, or $2 per minute. The tailing runs by gravity to the dump, while the concentrate-launders lead to storage-bins below the mill, where the material is unwatered and the water pumped back to the jig-floor. From the bins, the concentrate is loaded into wagons and hauled to the railroad, a distance of about one mile, down a steep grade.

	Silver Oz. per Ton			Lead Per Cent			Zinc Per Cent			Iron Per Cent

During August, 1906, the coarse-jig, Wilfley, vanner, and fine concentrates ran lower and the tailings much higher. This leads to an interesting fact. Up to August 1, the mill had been running with two shifts of 12 hours each, the mill-crew being made up of experienced men. Shift-bosses were getting $5 per day, and all millmen $4. On the first of August the eight-hour system was adopted, and the men were cut to $3.50 and the shift-bosses to $4.50 per day, and the result was that the crew walked out, and the places were filled by green men, many of whom had never been inside a mill before. During this month the concentrates ran lower and the efficiency of the mill was a good deal less, to say nothing of the extra wear and tear on the machinery from improper care and handling. Assuming that the mill-feed was of the same grade, and that the same weight of concentrate was made per ton of ore treated, as before, and that the lower assays resulted from lead and silver going down the creek, and not from making a bulkier concentrate of lower grade, which standpoint is sustained by the fact that the tailing ran higher, it is plain that the mill would have lost daily about four tons of lead and 250 oz. silver, a loss of about $600 per day, or $18,000 for the month. How much did the company gain by the cut in wages? It is a common saying that it costs a company $1,000 to break in a new jig-man, and these figures seem to bear out this idea, as about a dozen new jig-men were tried during the month. These deductions are only intended to be general and their accuracy is vitiated in this case by the fact that the water supply was especially low during this month, and the new wooden jigs were just being started. By the end of the month, either good millmen had been secured, or the new ones had become experienced enough to begin to understand their business, and the results improved.

At this mill the jig-men are encouraged to make a concentrate running between 60 and 65% lead. As the jig middling is not sampled, the result is that they run the concentrate-gates high, and the middling-gates low, making a clean concentrate at the expense of running much first-class into the middling. At the same time, in order to keep the tailing low, they must make much middling. In this way both rich and poor material are run into the middling, making a bulky middling-product and causing high losses in the slime, when reground. A better plan would be to demand that the jig-men make a concentrate running about 55 or 60% lead, and sample the middling as well as the concentrate and tailing. Then the jigs could be regulated intelligently.

A cable-tramway is being installed to carry the concentrate, coarse tailing, and crude ore from the mine, down to the storage-bins at the railroad, where they will be loaded direct into the cars, the ore and concentrate going to the Selby smelter, and the coarse tailing being used as road-metal. By this method, the water supply, which has always been inadequate, will be increased, as the coarse tailing will be unwatered and a centrifugal pump will elevate this water to the jig-floor.

The mill is run by six three-phase induction motors, starting on 110 and running on 220 volts, the power coming on a 60,000-volt line from Spokane, a distance of about 100 miles. There are six motors—one for the crusher, of 15 h.p.; one of 25 h.p., which runs the jigs, small trommels, middling elevator, shaking screens, small pump, etc.; one of 50 h.p., which runs the two sets of coarse rolls, two big trommels, main elevator, shaking feeder, etc.; a 50-h.p. motor for the two sets of centrifugal rolls, the Huntington mill, and baby trommel; and a 40-h.p. motor, which runs the elevator, and all the tables, vanners, and machine-shop machinery; a sixth motor of 15 h.p. runs the Smith-Vail pump on the lower floor.

Daily readings of the watt-meter for one month, all shut-down time being deducted, when the mill was handling about 250 tons per 24 hours, showed an average consumption of about 106 kw.hr. per hour, or 142 horsepower hours, a consumption of about 14.2 h.p. per ton of ore. The current passing through this watt-meter ran all the mill machinery, as well as the crusher for first-class ore, all mill-lights, sample-dryers, pumps, and the machine-shop.

The mill is run with three shifts of eight hours each. The regular mill crew consists of one crusher feeder, one jig-man, one Huntington-man, one vanner man, and a shift-boss. The millmen all get $3.50, and the shift-bosses $4.50 per day. Besides this regular crew, which changes shift every two weeks, there is a permanent day-crew, consisting of a repair-man and helper, a machinist and helper, one or two roustabouts, a mill-carpenter, and a general foreman. The mill is heated by steam from a wood-burning boiler.

Beginniug with January of this year, experiments were made in saving the zinc. A concentrate was made on the second screens of the No. 20, 12, and 5 jigs, which ran about 30% zinc and 12% lead, for which product the company found a market. To make a product so free of lead, it was necessary to run the first-screen gate low, which meant a lower-grade lead concentrate, and the scheme was abandoned. Another change that is being made is the installation of two 80-mesh Callow screens, to size the fine product on the Huntington-floor. There is an increasing tendency throughout the region toward using sizers rather than classifiers for fine material destined for table or vanner-treatment.

The general question might be raised as to the advisability of equipping a concentrating plant of this size with a single 6-ft. Huntington mill for fine grinding, instead of two 5-ft. mills. The excellent arrangement of storage-bins in the Hercules mill makes this point of less importance there, but even there the arrangement is often found unsatisfactory. In the first place the 6-ft. mill is a little too large for one man to handle easily. With the aid of good chain-blocks he may be able to substitute a new muller for a worn one, or to put the shoe in to smooth up the ring, with perhaps an interval of half an hour between stopping and starting. But in changing the bull-ring, or other heavy repairs, the unhandiness of this size as compared with the 5-ft. mill becomes apparent. A crew of four men will often consume eight hours in changing one of these rings, on account of its weight and unwieldiness, when a smaller crew could make a similar change in three or four hours with the smaller mill. If the new bull-ring happens to have a soft spot in it, it may become useless and break from the pounding of the mullers, while yet practically unworn, and the mill must be stopped again for a shift. Besides, when running with the storage-bins nearly full, as often happens, it may become necessary to make some repairs on the Huntington. In these cases, when the single mill is used, the jig-middling gates must be closed, and the middling run into the tailing until the Huntington starts again. This may result in a serious loss. A common trouble with this mill has been the dropping of the horizontal gear-wheel until it meshes too deeply in the driving-gear, and jacking it back and keying it takes time, especially when this happens during either of the night shifts, when no repair-crew is about. The heating of the step is not unusual, necessitating a shut-down to thoroughly clean and oil this bearing or put in new bearing-buttons. Considering the question in the light of these practical points, it would seem that the use of two 5-ft. mills here would be an advantage, especially as the difference in the first cost of the machines is comparatively negligable, and more capacity at this point would provide against overloading, and also relieve the centrifugal rolls, which are crowded hard when the Huntington is closed, as they then get all the oversize from the small trommel. When a Huntington is used as a re-grinder, it must handle what feed is sent to it, and the amount of work it must do is not regulated by the operator, but by some one on the floor above, who does not worry about the Huntington man's troubles, and for this reason an elastic capacity is quite essential. In addition to all these considerations, I think any man who has worked for a length of time around a 6-ft. mill, with no repair-crew available, will agree with me in choosing the smaller size.

The accompanying flow-sheet shows the course of all ore in its passage through the mill. This system will soon be slightly modified by the addition of the two Callow screens.

MINING IN MALAY.—A British authority on mining conditions in the Federated Malay States says that the Malayan miner has two bad qualities. He still holds human life dirt cheap when he gives reins to passion, and he is probably the most inveterate and incurable gambler on earth. When, consequently, bad luck attends his speculations, there is always danger of his squaring accounts with Fate by miscellaneous stabbing. Running amuck is regarded in the peninsula as the natural result of losses at play. Here, then, would appear to be a most promising opening for that Radical reforming zeal, which, in the case of certain other Asiatic miners, would expel Nature—and the toilers themselves—with a fork. But there is one code of morality for Malaya, and quite a different one for the wicked Rand. It is proposed by the Colonial Office to confine the prohibition of the gambling farms in Malaya to non-mining areas, leaving them in full operation elsewhere. By this curious method of discrimination, the revenue derived from letting the farms, usually to Chinese speculators, will be maintained, while should some thin-skinned Radical protest against the vice being turned to account for State profit-making, it will be pointed out how gambling farms have almost vanished from the non-mining districts, where they have never been in nearly so much request.

COAL-TESTING PLANT IN DENVER.—J. A. Holmes, of the United States Geological Survey, has concluded negotiations for the land upon which a Government coal-testing plant will be constructed in Denver, Colo. The Chamber of Commerce of that city agrees to furnish the land. A completely equipped laboratory, with special apparatus for the treatment of coal and its by-products, will be built. The difficulties encountered in winding generators for potentials of 20,000 or 25,000 volts are primarily mechanical difficulties. A coil containing a large number of small wires does not make a very mechanical piece of work. It would, therefore, appear to be desirable, that the individual coils should consist of as few conductors as possible and that these conductors should be of such size as to enable the making of mechanically and electrically strong coils.

MINERALS IN ABYSSINIA.—Alluvial gold is found in considerable quantities on the Blue Nile and its tributaries. No reefs, containing gold in workable proportions, have yet been discovered. The difficulties attending the transport of machinery render it at present impossible to undertake any serious working. Iron is abundant and coal is known to exist in various parts. Silver, copper, and sulphur have been found. At present the impossible terms of the concessions granted for the exploitation of minerals have prevented any of them being seriously considered.

Converter Lining.

Written for the MINING AND SCIENTIFIC PRESS
By H. L. CHARLES.

Line the converter in the usual manner, then plug the tuyeres on the inside with stiff clay; fill the converter with slag (preferably converter slag, but slag or low-grade matte from blast or reverbatory furnaces may be used) and set away for one, two, or three hours; then pour out the molten slag and allow the shell that will form to cool off gradually. In about eight hours the converter will be ready to go back into service. Plenty of vent-holes should be provided in the shell to allow the steam and water to escape. The bottom should be tamped in about two inches deeper than when the fuel is used, to allow for the proper depth below the tuyeres for the shell that will naturally freeze on the bottom. The core should also

Fig. 1.

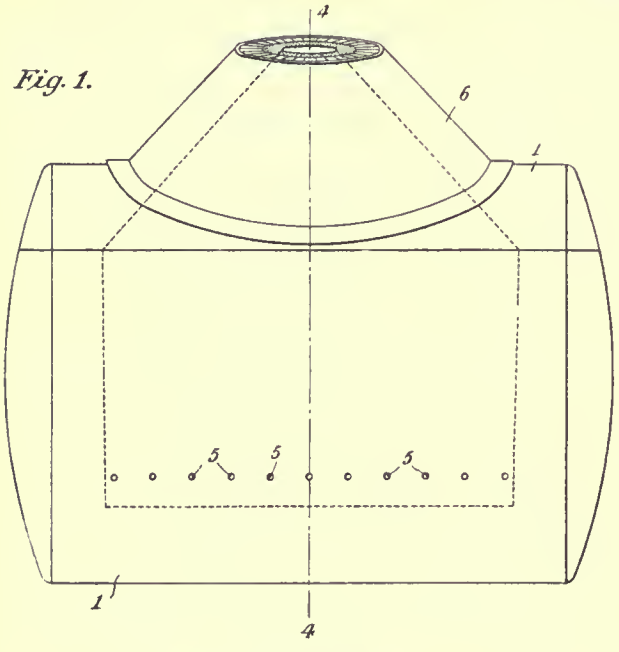

Fig. 2.

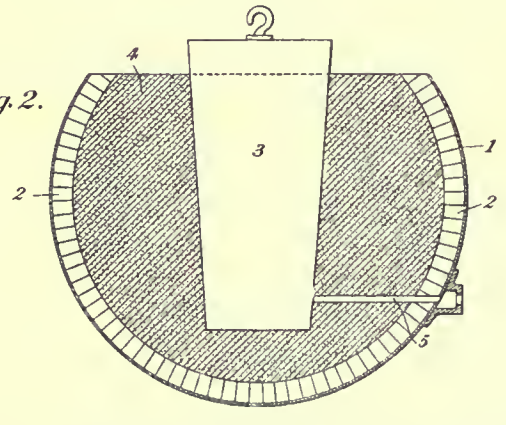

be three inches longer and two inches wider than when formerly used, to allow for the shell formed on all sides. The slag-shell should be knocked off on the tuyere side to prevent the first charge from spilling out and also running cool. By this process a more even corrosion of the lining will result, as well as a longer life for each lining. No caving down of the lining will be found from this method of drying, while it is quite frequent from fuel-drying. With the old way of drying it usually takes four and sometimes five shells for each stand, while with this process I am using about two and one-half shells per stand and could get along with two. With the longer life of the lining, I am making from one to three charges more than when we were using fuel for drying.

The process is now in use at the Butte Reduction Works at Butte, Montana, at the Boston & Montana smelter at Great Falls, Montana, and at the Bingham Consolidated smelter in the Salt Lake valley. Many others are commencing to use it, and should any metallurgist desire to learn more about the process from one who has used it for the past eight months successfully, he can write to A. H. Wethey, the manager of the Butte Reduction Works, who will outline the advantages, as he has used nothing but the slag-drying method at their new plant for the past eight months.

MALAY WOMEN AS GOLD MINERS.—Under a recent order made by the Resident, the royalty payable on alluvial gold won by persons working under individual mining licenses in the State of Pahang, in the Federated Malay States, has been commuted for a fixed payment of

Fig. 3.

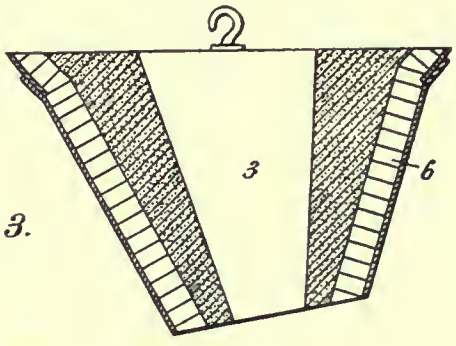

Fig. 4.

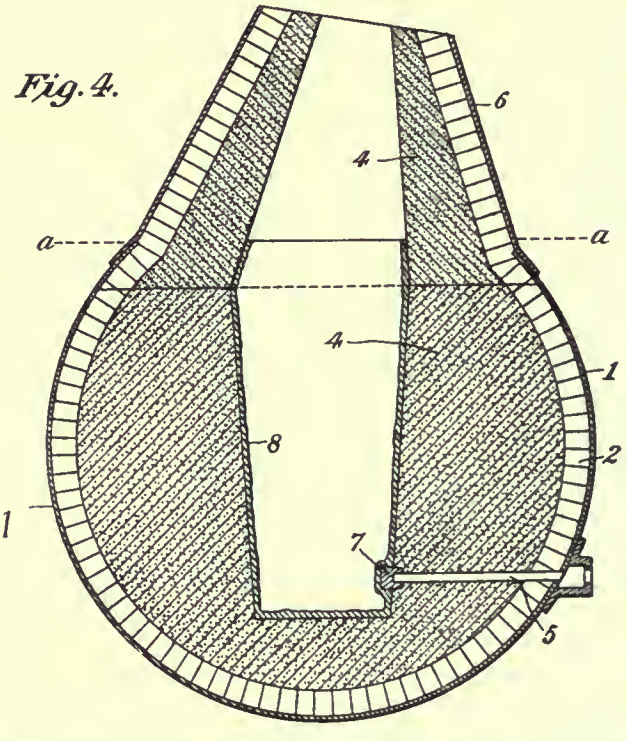


$5 a person per year, half rates being paid for six months or less. This alluvial industry is, according to the *Pinang Gazette*, assuming fairly extensive proportions. A feature of the work is that large numbers of Malay women are engaged and are keener on it than the men. They take great pains to wash carefully selected sand for small quantities of gold. The ore so obtained is seldom or ever exported, being either made into rough jewelry or sold to the local Chinese. Another form of primitive mining, favored by the Malays in many parts of the Ulu, is called *meriau* or *melanda*. Like the fossicking for alluvial gold, it consists of washing the sand of selected river-beds for tin ore, and here again the women are much in evidence and do more of this kind of work than the men. With a little luck and some perseverance, a fair quantity of ore is usually won in this way, from 50c. to a dollar's worth being obtained by one worker in a day, which is ample for the average Malay family to live on.

The Renaissance of Nevada.

Written for the MINING AND SCIENTIFIC PRESS
By a Special Contributor.

The last few years have witnessed a wonderful revival of mining in the deserts of Nevada. The great volcanic area in the south and west, with its numerous irregular ranges and isolated buttes surrounded by a barren wilderness, are now the scene of an intense industrial activity.

When Tonopah was first discovered by J. L. Butler in 1899, the nearest railroad station was Sodaville, on the Carson & Colorado railroad. Across 60 miles of deep sand the track was laid to Tonopah, and this active little town has been established with 5,000 inhabitants and many of the conveniences and even luxuries now considered essential to modern life. The development of Tonopah in 1900 was only the breaking of this wave of development, which is now sweeping over the desert, leaving in its path mines of proved richness.

Nevada is undeveloped and only partially prospected. Many years ago the country was run over, productive mines were found and 'gophered,' but in most cases they died a natural death, victims of the desert. Of the old Nevada mines, the Comstock alone rivals the prospects of Tonopah and Goldfield. Austin and Pioche in the sixties were important producers, while the development of the Comstock in the seventies was accompanied by important discoveries at Mountain City, Jefferson Canon, Tuscarora, Ely, and Candelaria. Of these camps, Ely is now developing into one of the chief copper producers of the United States. Until recent years, copper has been neglected in Nevada and though several occurrences were known, they were generally left as valueless owing to difficulties of transportation. It is the richness of Tonopah and Goldfield that has enabled operators to overcome the local difficulties. These high-grade mines have built railroads, supplied electric power and water, and have triumphed over the opposition of nature.

The present movement covers a great area, not restricted to the southwest. Deposits of unusual promise are being developed from Rosebud, north of Reno, to Greenwater and the Colorado river.

There are three leading features in the development of this region, namely, the geological conditions, transportation, and available capital.

The topography tells the tale of the rocks. Isolated peaks and broad mesas, the natural result of denudation of volcanic necks and recent lava flows, surround the sage-brush plains. The repetition of these volcanic outbursts since the period of mineralization has in many cases an important bearing on the mining for gold. It has necessitated a careful study of the geological conditions and systematic exploration, in many cases with scant surface indications. Tonopah is a striking instance. The surface showings were confined to a small block of an earlier andesite roughly a quarter of a mile square. As a result of intersecting faults which dip away from the centre of the block, the productive area in depth is much larger than that indicated on the surface. The Montana-Tonopah shaft, sunk on a tract showing no outcrops, intersected this productive andesite at about 350 ft. and developed one of Nevada's greatest mines. This is a common feature in the desert, which makes a careful study of the geology essential, and often makes the productive area greater than is at first supposed.

The majority of the gold and silver camps are in volcanics of Tertiary age, the earlier flows being followed by a general mineralization by ascending hot waters during the decline of volcanic activity.

Prospecting in the desert is hard work. There is no game, no timber, and but little grass or water. The country is such as to facilitate transport, but the necessity for carrying everything is a serious drawback. There are few places that cannot be approached by wagons, but the everlasting question of water supply is always at hand. Two prospectors often take all their available supplies on burros, but not uncommonly one man spends all his time packing water, while his partner is prospecting. The straying of horses or burros (donkeys) is a constant trouble in the desert. Often they are taken to wells to pack water and to get a drink, but all the persuasive powers of the prospector will be useless to make them imbibe, although he knows that as soon as they get back to the camp, they will drink half of the water they have carried on their backs. But the most important feature in recent times is the automobile. Formerly the prospector would tell the promoter of the wonderful riches of the "biggest mine on earth"—usually a far-off deserted prospect, exaggerated by the hardship of the journey. But now it is common to see automobiles racing across the sand to see some discovery a hundred miles away on the flimsy evidence of a few specimens. And the 'prospects' in most cases consist of an outcrop only, rarely is there so much as a 10-ft. hole in the ground. An ordinary prospect with a shaft over 50 ft. is considered a mine, and in Nevada it fetches the price of a developed mine. The influence of the automobile in destroying the supposed horrors of the desert and in bringing the prospector in contact with capital, cannot be overestimated.

The general tendency during next summer will be to prospect the northern part of the State. In Churchill county, Wonder, a district possessing geological features similar to those of Tonopah, will be the centre of attraction, while Rosebud in the Seven Troughs district promises to become productive. At the latter place an important find was made last August. A flinty rock, resembling chert, formed an unpromising outcrop. It showed no valuable minerals to the naked eye. An assay gave returns of 13 oz. gold and 56 oz. silver per ton, and the first shot disclosed ruby silver ore. The property is now under development. The deposit is another of the occurrences that surprise the geologist in Nevada.

Railroads are being built in many directions, as fast as men and material can be collected, and already two are being built toward Death Valley. Copper has recently received a great deal of attention in western Nevada, both from prospectors and capitalists. It is a metal dangerous to those that do not employ specialists. Few of the people who are taking up copper prospects in Nevada have any conception of the many-sided problem presented by the production of copper, and as a result there is great danger of enthusiasm not tempered by judgment.

Smelters are discussed without any consideration of the all-important questions of fluxes, fuel, and water, while prospectuses of the most absurd character are floating broadcast. An interesting document recently described a district as a second Butte, saying that some malachite had been sold for $7 per pound for gem stones. A discussion as to smelting methods was followed by a confession that the total development was a 10-ft. hole showing wonderful oxidized ore. It is essential to secure a smelter site in good time, as they are few, but with the exception of Ely and perhaps Yerington, there are no copper mines sufficiently developed to warrant reduction works. But under this veil of absurd advertisement, there is progressing a surprising amount of steady development, which will, in some cases, produce important results. In the Yerington district, important deposits, suggestive of Globe, Arizona, are being systematically developed. The country, a highly metamorphosed limestone, with altered and garnetiferous zones, rich in epi-

dote, would immediately suggest copper. Sixteen miles from Wabuska in the foothills bordering Smith valley is the Nevada-Douglas Copper Co.'s property. Here there is an important mineralized zone in the limestone, which is altered and tilted by porphyry dikes to the north. The orebodies occur in this garnetiferous limestone at the intersections of fissures and, being due to replacement, they are irregular. Throughout the district the carbonates, also atacamite, and the red and black oxides occur with copper glance, and these oxidized ores, with their beautiful green and blue coloring, adorn many brokers' windows. Their very beauty has done much to create an unhealthy excitement in copper prospects, which are, of all mineral deposits, the most difficult to value, especially in limestone. The shipping of rich oxidized ores from California in the sixties and the long chain of deserted mines from Placer county to Mariposa should be a warning to capitalists to use precaution in tackling this difficult but lucrative business.

Copper mining is an attractive enterprise at the present time, and important developments may be expected in Nevada. The limestone of Yerington should produce some deposits of high grade, while the districts undergoing systematic development to the east and west of Mina and especially in the Greenwater district, promise to become even larger producers.

Communication with Goldfield did not reduce the cost of supplies to any large extent, but without it the present progress would be impossible. Greenwater is more accessible than is generally supposed. With the railroads now under construction, it will be within 15 hours of the coast. It is not an ideal situation for a copper camp, but there is no danger of farmers, and water is available at Ash Meadows for smelting.

The question of capital in Nevada is perhaps rather a delicate subject. It has been hinted that the desert is a favorite resort for wild-cats, and that its value as a mining country is overestimated. Of course every new country, and above all the high-grade mining camp, must have its black sheep. Considering the conditions it is surprising what an enormous number of properties are being quietly and systematically developed by the people of Nevada and their friends without any brass band methods and in many cases without incorporation. It is necessary to draw a sharp distinction between small stock corporations that put the money obtained by the sale of stock into the ground, and those that sell stock with no intention of mining in a serious and legitimate way. The former have done much to develop the country and must not be confused with the parasites of the mining industry. They may show bad judgment, employ incompetent men, and many will choose hopeless prospects and fail. In this country, which has given so many surprising results, it is good policy—and the better companies realize it—not "to put all the eggs in one basket," but to take up prospects in different districts, if capital is available to 'hatch' the best of them. Conditions are changing and becoming better for the serious operator. Prospects can now be bonded on reasonable terms for development, and as a result many important mines will be heard of in the near future.

Of the nondescript wild-cat schemes little need be said. They are an unsavory element in every new mining camp that should be diagnosed by serious investors. Many will die a natural death in the next few months. A general depression in mining in Nevada is likely to result from a strained labor situation and general financial conditions, and this will be the last chapter in the history of most of the illegitimate mining schemes.

The future of many mines is assured, and the stockholders realize it. As a result, a depression will have its beneficial aspect. The causes of failure are many. Overenthusiasm and absurd capitalization of prospects coupled with an inability of many so-called engineers to gauge the difficulty of any undertaking in the desert, for which fuel and water are required, is becoming a serious menace to the mining interests.

The relations of operators and labor must be thrashed out and the country is ready to stand it now. If this necessitates a temporary shut-down, it will enable the railroads to relieve the present congestion and the camps will be scoured of many of their most undesirable elements and will return to a state of quiet and legitimate prosperity.

STREAM FLOW IN ALASKA.—The stream-flow measurements that the United States Geological Survey has been making for a decade or more on important streams in various parts of the United States were, during the summer of 1906, extended to Alaska, in order that information might be obtained regarding the amount of water available for the economical development of placer mines and possible water powers in that Territory. The results of the work have just been published as No. 196 of the series of Water-Supply and Irrigation papers. That such information is essential to the profitable working of placer deposits is not always fully realized, and the lack of it has often been responsible for the financial failure of enterprises that promised success. Limited funds and time necessarily restricted the investigations to a comparatively small area, and the Nome region of Seward Peninsula was selected because of its extensive mining interests. Stream-flow data were collected at 45 stations, and a careful study was made of the conditions affecting the water supply. It is believed that the data obtained, while far from exhaustive, give a fair idea of the conditions of flow that may be expected in the vicinity of the gauging stations, and that they will prove valuable in estimating stream flow in other parts of the region. As a result of the great value of the waters for use in the auriferous gravels, water-power possibilities on the peninsula have been neglected; but the development of a large number of excellent power sites is feasible both from an engineering and a financial standpoint, and the attention of mining men is directed to such development. The report summarizes the hydraulic development of the region, and contains a much-needed warning against construction and installation of expensive machinery without the necessary preliminary investigation and engineering advice. The report may be obtained free of charge by applying to the Director of the United States Geological Survey, Washington, D. C.

TUBE-MILLS.—The tendency is to shorten the tube-mills in use on the Rand. At the Village Main Reef, the length of tube has been 22 ft. and the early machines were two feet longer. In ordering new tube-mills it is specified that they shall be 5½ ft. shorter, that is, only 16½ ft. The diameter remains unchanged. It is hoped to decrease power consumption.

SUMMER SCHOOLS.—The Massachusetts Institute of Technology, Boston, issues a syllabus of the summer courses for June and July, 1907. Cornell University publishes an announcement of the sixteenth summer session, in July and August.

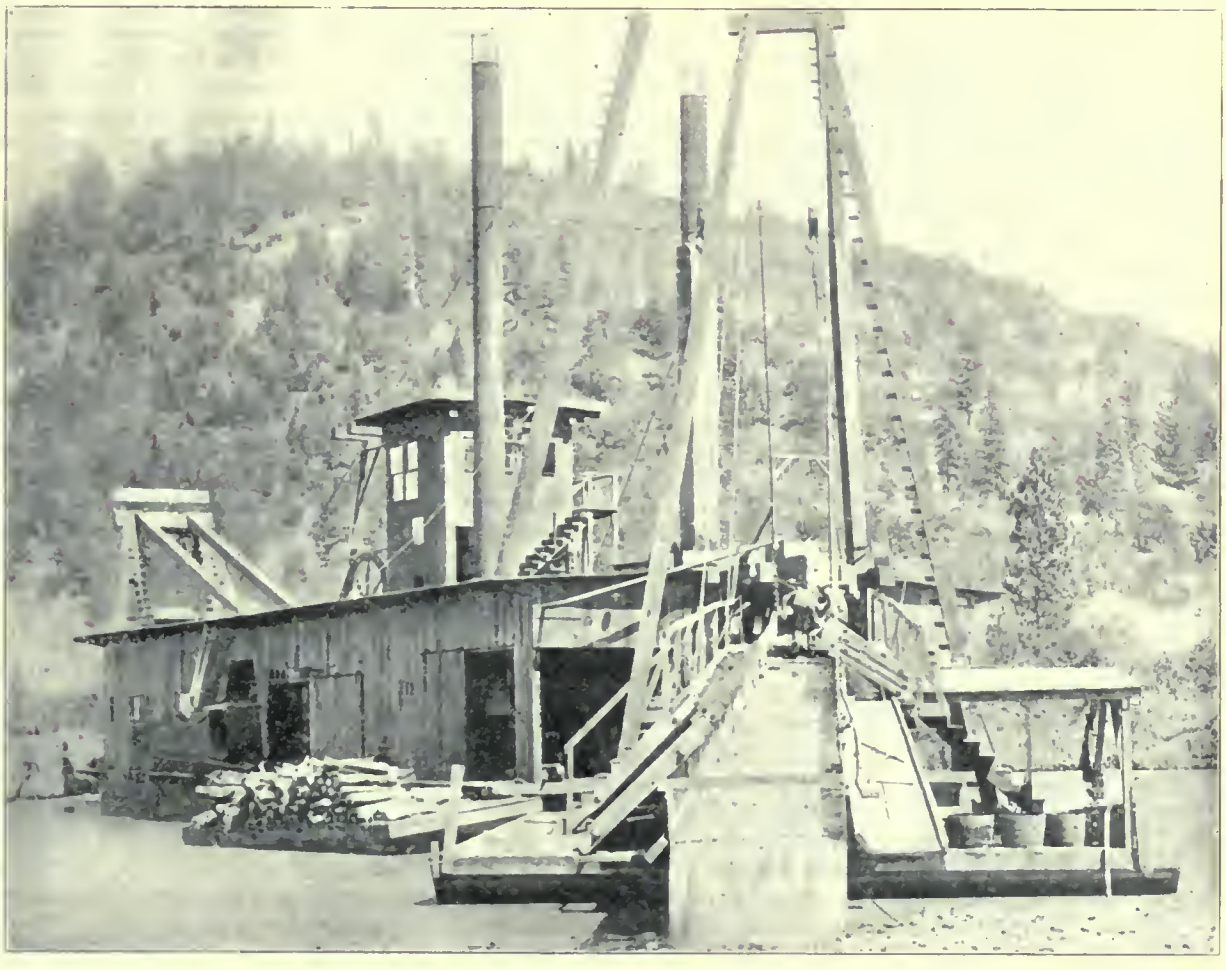
CRIPPLE CREEK DRAINAGE ADIT.—Bids for the construction of this deep 'tunnel' in the Cripple Creek district, Colorado, will close on May 15, 1907. Applications should be made to E. D. Marr, Secretary of the Tunnel Company, at Colorado Springs.

Sluices and Riffles in Dredging.

Written for the MINING AND SCIENTIFIC PRESS
By DENNIS H. STOVALL.

The best sluices ever tried on the Oregon dredging field are given a separate barge on which to float, and besides the 120 ft. of flume outside the dredge, a double system of grizzlies is employed inside. It is easier and less expensive to save 90% of the gold in the gravel by ample sluices, riffles, and flumes, than to provide more powerful equipment with which to dig or scoop out twice as much ground but save only 45 per cent.

By mounting the outer flume and riffles on a separate barge, it can be swung from point to point and thus allow ample dump-room and obviate choking. The outer flume has a width of four feet, with a drop from end to end of seven feet. It is mounted to the barge by trestle, and is perfectly balanced, so that it is easily swung by cable from the pilot house of the dredge. This flume or sluice is provided with Hungarian riffles.



Pontoon Carrying Sluices of a Dredge. Flume 120 Ft. Long.

In working cemented ground, such as is found in southern Oregon, and in other Pacific Coast districts, much agitation and an abundance of water is necessary; otherwise a great part of the gold will be lost. It is on ground of this character that ample sluices and riffles prove effective, and, in fact, a dredge thus provided is the only machine that has proved a success.

In a dredge of this type, the gravel is dropped from the buckets into a hopper on the deck. This sheer drop of from 10 to 15 ft. in itself proves effective in breaking up the cemented gravel. From the hopper it is conveyed to a revolving grizzly, with perforations five or six inches in diameter. This grizzly operates much on the principle of the 'riddles' of a threshing machine, shaking over all the coarse stuff, and dropping the smaller and lighter through the holes. The interior of this grizzly is supplied with a number of jets, by which a fresh and additional supply of water is thrown upon the gravel. The large boulders are separated from the small, and slide over the grizzlies to the side of the boat, where they are dumped, the remainder of the material passing through a funnel-shaped conduit to a settling-tank. It is in this settling-tank, which is provided with Hungarian and strap riffles, that a great portion of the gold finds lodgment. From the settling-tank the remainder of the water and gravel is carried or elevated to the upper end of the long sluice-way outside.

As already hinted, a system of sluices and riffles of this sort requires an abundance of water, and to supply this water there must be pumps of ample capacity. In the dredge using this particular system, centrifugal pumps are employed. These are two in number, the first being a six-inch pump to give water for the upper or double set of grizzlies. Water is first admitted at the hopper where the gravel is dumped from the buckets. This water assists in melting the cemented or compact ground, and also flows down and aids the grizzlies in their work of disintegration.

After the sand and gravel have left the well or settling-tank, which is the second step in separation, it is lifted or conveyed by a 12-in. centrifugal pump to a height of 16 ft., or to the head of the outer pontoon sluice. The riffles can be easily lifted and rinsed, and are effective in saving the gold. As is proved by the gold in the settling-tank, the best method of gold-saving is one that obviates boiling as much as possible. The grizzlies and flume are given a fall of one inch in five. All are provided with replaceable linings by which the finest gold is caught.

On a machine of this character, where cemented ground is handled, ample provision must not only be made for

thoroughly breaking up the gravel and separating the metallic particles, but it must be built to withstand twice the strain to which a dredge is subject on average ground. The barge of the machine, as illustrated herewith, is iron-strapped and bolted, and the stud timbers, 112 ft. long, are 3 by 3 ft., and cut from whole trees of Columbia River yellow fir, a wood that has great elasticity and strength. The digging-beam for this dredge is 80 ft. long, and serves the purpose also of a frame for the chain, the latter carrying 45 buckets of eight cubic feet capacity each. The alternating links are of the slug or telescope pattern, with multiple-connecting projections, and is one feature of the dredge that gives it great strength. The lifting force of the machine is 80,000 lb., and this force is exerted principally on the digging-frame, and conveyed through the machine by the stud-timbers, none of the strain coming on the shell or hull of the barge, thus obviating leaks and breaks.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

A cleavage fragment of Barite was sent by G. E. W., of Los Angeles.

J. H. K., of Paradise, Ariz., sends a specimen of Granite somewhat mineralized with Pyrite.

The three rocks marked S. S., Hahn's Peak, Colo., are: No. 1, Slate; No. 2, Quartzite; No. 3, Slate.

The specimens from F. E. W., Redding, Cal., are: No. 1, Quartz, Pyrite, and Calcite, with crushed country rock; No. 2, Pyrite in Quartz; No. 3, Quartz with a little Pyrite.

The rocks from Placer county, Cal., sent by W. B. H., of San Francisco, are: No. 1, amphibolite Schist; No. 2, volcanic Tuff; No. 3, volcanic Tuff; No. 4, sericite Schist; No. 5, altered mineralized Schist.

The rocks from Jalisco, Mex., marked L. B., are: No. 1, altered volcanic rock perhaps Andesite; No. 2, brecciated Andesite; No. 3, Diorite; No. 4, banded Rhyolite, No. 5, Pyrite; No. 6, altered volcanic rock.

C. H. F., of Christmas, Ariz., sends: No. 1, Quartzite with Pyrrhotite; No. 2, contact rock with Epidote; No. 3, serpentinized rock with Pyrite; No. 4, serpentinized Diabase; No. 5, Diabase; No. 6, black Slate with Chalcopyrite.

The samples from Hillside, Ariz., marked A. L., are: No. 1, Quartz and Limonite; No. 2, Copper-stained rock; No. 3, Quartz, with Iron and Manganese oxide; No. 4, Quartzite; No. 5, Magnetite; No. 6, Quartz, with red Hematite.

The mineral specimen from J. N. McL., of Denver, contains Silver and Copper, with Tellurium instead of antimony. No reaction was obtained from bismuth. Resembles hessite, but requires a chemical analysis definitely to determine the species.

A. B. C., of Battle Mountain, Nev., sends: No. 1, Quartzite; No. 2, Quartzite; No. 3, Slate; No. 4, Dacite. The darker pieces of dacite contain black glass and are probably a contact phase of the lighter crystalline rock. The inclusion is shale. The clear grains from the wash are quartz.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

A re-location of a mining claim can be made only where there has been a prior valid location, and the rights of the original locator have terminated. A re-location is authorized only for forfeiture or abandonment of a prior location. By making a re-location the locator makes admission of the validity of the prior location and precludes himself from contesting it. "Mining claims are not open to re-location until the rights of a former locator have come to an end. A re-locator seeks to avail himself of mineral in the public lands which another has discovered. This he cannot do until the discoverer has in law abandoned his claim and left the property open for another to take it up."

Zerres *v.* Vanina, 150 Fed. 564. (Jan., '07.)

A notice given by a re-locator is said to be a solemn admission in an instrument which is made a matter of record that such re-locator is not a discoverer of mineral, but an appropriator thereof, on the ground that the original discoverer had perfected his right. It becomes in a certain sense an instrument of title, a record; and it is the equivalent of an admission of record to the original locator that such re-locator claims a forfeiture by reason of a failure of the first locator to make his annual expenditure.

Zerres *v.* Vanina, 150 Fed. 564. (Jan., '07.)

The owner of a mine is liable to the owner of property on a stream below the mine for damages that result from acidulated and offensive water pumped from such mine and thrown into the stream, although such disposal of the water was necessary to the operation of the mine.

Bowling Coal Co. *v.* Ruffner, (Tenn.) 100 S. W. 116. (Feb., '07.)

Where the grantee in a deed of certain lands agreed that his grantors could remain in possession of the premises during their natural lives without the payment of any rent. At the time of the conveyance there was a coal mine on the land which had been opened and operated. The grantors occupied the land and mined coal from such open mine for eleven years. Under these circumstances it was held that a person claiming under the grantee could not dispute the life estate of the grantors in the coal.

Robb *v.* New York &c. Coal Co., (Pa.) 65 Atl. 938. (Jan., '07.)

In this connection it may be stated that the general rule is that a life tenant may continue to operate a mine that had been open and operated prior to the time that he acquired his estate.

The fact that the negligence of an employee operated with the negligence of the employer to produce an injury to a co-employee, which resulted from the negligent failure to properly prop the roof of an entry to a mine, was held not sufficient to relieve the operator of the mine from liability.

Madden *v.* Saylor Coal Co., (Iowa) 111 N. W. 57. (March, '07.)

In order to entitle an employee to recover for injuries received by the falling of the roof of an entry to the mine of his employer, it is incumbent upon him to show that the employer was negligent in using props in the manner he did, and he may show another safe and convenient way of supporting such roof. And where the employer offered evidence of a custom of supporting similar entries, it was held competent for the employee in rebuttal to show how the roof of an entry should be timbered.

Madden *v.* Saylor Coal Co., (Iowa) 111 N. W. 57. (March, '07.)

The proprietor of an open estate has no legal right to discharge into a natural stream the waste oil and salt water proceeding from wells sunk on his premises, and he is responsible for any damages resulting therefrom to an estate below.

McFarlain *v.* Jennings-Heywood Oil Synd., (La.) 43 So. 155. (Feb., '07.)

Editorial.

LETTERS FROM a self-made miner to his new foreman ought to give some useful hints to those about to manage a mine, and therefore Mr. Matt. W. Alderson's correspondence will be read with interest. The correspondence is fictitious, but it will be found strangely true in its regard for the essentials of practical mining. We expect to publish four of these letters in successive issues.

SUCH contributions as that of Mr. Charles D. Kaeding, on the method of building foundations for a mill in Korea, are of especial value. The writer is the assistant general manager for the Oriental Consolidated Mining Company and supervised the work that he describes. Any record of the weak parts or the successful features of a mill, as made manifest in the course of work, are of particular value to the profession.

STEAM-SHOVELS are becoming an interesting feature of copper mining, especially at Bingham and Ely, where large masses of soft porphyry can be exploited by this method. Mr. J. W. Abbott's notes on Bingham will prove interesting. The illustrations remind one of the big iron mines of the Mesabi and suggest the dimensions of the copper deposits into which the steam-shovel will dig.

OUR LONDON CORRESPONDENT gives an interesting abstract of the annual reports of some of the big West Australian mines and, incidentally, these afford an example of the change that has taken place in English methods of keeping mine accounts. Development and exploration are no longer debited to capital, and new mills are no longer erected with funds raised on debentures. The revenue account is made to carry them all, as it ought to do, for a mine is a liquid asset in the sense that it is running away, as its resources are exhausted by mining and milling. There was a time when machinery stayed on the books as 'capital' long after it was valuable chiefly for scrap iron, but nowadays each year a large fraction of the original cost is written off the accounts for depreciation, so that the price of it has been wiped off the books before it has ceased to be useful. The machinery of an exhausted mine is a pathetic derelict. Time was also when 'dead work' was debited to capital, so that mining costs appeared beautifully small, and the manager got great credit as an economist. But such methods are now in bad repute, and the management of mines at London has gained by the accumulated experience of the last generation. In these matters such houses as John Taylor & Sons, the Exploration Company, the Consolidated Mines Selection Company, and Bewick, Moreing & Company have served to educate directors,

and legitimate mining owes them a debt that it is pleasant to record.

THE SURVEY AT WASHINGTON issues press bulletins, of which the last is numbered 278, series of 1907. In the lower corner the announcement is made that Mrs. Harriet Connor Brown will relinquish to others the "pleasant duty" of preparing these bulletins, as she is changing her residence to Chicago. While we have not availed ourselves of the material furnished in these bulletins as much as some of our contemporaries, nevertheless we would like to be first in recording the general excellence of Mrs. Brown's work and in wishing her good fortune in her new sphere of activity.

NEW YORK has another mining market, for the Produce Exchange has a new department in which mining shares are bought and sold. As yet the business done is small, but it looks promising, at all events it is marked by more dignity and comfort than the peripatetic bourse on the Curb, and it is more distinctive than the dealings in three or four mining companies now quoted on the regular Stock Exchange. Considering the magnitude of the business done at New York in mining stocks, it is curious that there should be nothing to compare with the mining department of the London Stock Exchange. A well organized mining exchange or a representative subdivision of the Stock Exchange would be of great service in facilitating dealings and in regulating them, so that the gambling of the moment might tend to separate itself from the sane speculations afforded by reputable companies. The business of mining has reached dimensions warranting better recognition from the brokers of Wall Street. At present the Curb is the principal market. It is something of an absurdity, especially in wet weather. Moreover it is used in advertising new enterprises, for stock sold privately between brokers on the Curb can be recorded in the newspaper quotations of the day and thus a fictitious market is created, sufficient to attract the inexperienced. It is a free-for-all institution, offering every facility for 'wash shales,' that is, a transaction in which two brokers make a fictitions trade for the sake of recording a quotation. The Curb is chosen, in preference to the Stock Exchange, by companies that dislike to furnish information concerning the details of their business; that is why Standard Oil is a Curb stock; the same applies to the Northern Securities and to other issues of a mysterious kind. The members of the Exchange dislike it, as is reflected in the story of the broker who was asked by a yonng woman at a dinner party what he thought of Omar Khayyam and he replied harshly: "I never deal in Curb stocks."

GOVERNOR SPARKS is at it again. We do not know him, nor have we any prejudice against him personally, except on one account, namely, the lending of his name to mining companies of a questionable sort. A full-page advertisement in a daily paper announces that "Governor Sparks' Company makes a first shipment of ore," and then follows the statement that this is the "last chance to buy this $5.00 stock at 50 cents. Price advances to 75 cents on Saturday." Mr. John Sparks is Governor of Nevada, and he ought to have more respect for his honorable office than to play the fool in this way. People do not offer a stock worth $5 (omitting the pretentious ciphers) for 50 cents; any man that buys something worth $5 for less than $5 can expect to get $5 worth of experience, and nothing more. The mine that is making this loudly heralded first shipment of ore is "conservatively capitalized at $5,000,000," and "in view of its immense acreage, and the millions of tons of ore known to be in the 50 claims, a capitalization of $20,000,000 would not be inconsistent." No, it would not; it is as easy to get acreage in the desert as it is to water the stock. The whole affair is so bad as to mark the crest of speculative folly in wild-cats. Here is the superintendent making a sworn statement that he has 120 tons of ore sacked and ready for shipment. A lower assay company certifies that some samples yielded 11.5 per cent copper, and to this is added the information that "many of the world's greatest copper mines produce ore that assays only from 3 to 7 per cent copper." This is true, but the inference is false, as false as words can make it. Assays do not make a mine. The whole thing is preposterous. The Governor ought to be ashamed of being the president of such a company, as of others with which he has been connected. The use of his portrait as part of a flamboyant advertisement brings ridicule on the office that he holds.

Affairs on the Rand.

OUR CORRESPONDENT at Johannesburg is always interesting, but last week his letter was of more than usual importance. Owing to the apparent drifting policy of the new Government, the outlook for labor is distinctly bad in the Transvaal and the future of the mines is endangered. On the face of it the statement that the Boers consider it better to make the mines last a long time, instead of pushing the production, seems likely to be true, for that is the idea in most countries except America, Canada, and Australia, the inhabitants of which are mostly in a hurry. Modern ideas on the exploitation of mines favor that rate of production which will yield the maximum ultimate profit, that is, looking at a mine as a mass of ore, it is the purpose of the engineer to take it ont and extract its valuable contents in such a way and in such a time as will give the biggest return on the capital employed. It is possible to extract ore so fast as to be wasteful, not only because of the carelessness that accompanies an extravagant production, but also because too rapid operation leads to the neglect, and eventual loss, of a certain proportion of low-grade ore, the treatment of which at a profit is likely to be made possible either by an enlargement in the scale, rather than the rapidity, of operations, and by the metallurgical improvements that are constantly being devised. Thus, the bonanza mines at Kalgoorlie and at Johannesburg wasted a lot of good ore in the early days of those districts, when costs were high.

making a profit per ton only a half what the same ore would yield now under better conditions. On the other hand the exaggerated European, and also Mexican, way of running a mine in the interest of a deserving management or an amicable community, and spreading the output over a long term of years in order to keep engineers and workmen pleasantly employed, leads to a loss of profit, because fixed expenses eat up an excessive proportion of the yield. The amortization of capital is a phrase the real meaning of which, as applied to mining, is a thing of yesterday. It does not appeal to the Boer, who looks at the gold mines from the standpoint of the fixed community in the Transvaal rather than the shifting body of shareholders in Europe. Our correspondent is an engineer with a keen sense of responsibility, therefore his statement concerning the closing down of some of the poorer mines, is serious. The withdrawal of capital, which also he predicts, is much to be regretted, for while some of it will be diverted to America, the first result will be to undermine confidence in mining as an investment and to accentuate the dependence of all industry upon an unstable and increasingly expensive labor supply.

Secondary Enrichment.

ORE DEPOSITION is a subject of perennial interest, and in this issue Mr. Hiram Hixon revives a discussion, to which we hope others will contribute. Mr. Hixon is always interesting in his expression of opinion, because of his delightful independence, which often takes the shape of originality of thought. As regards the theory of secondary enrichment, there is no doubt that it has gone far to illuminate the perplexities of ore occurrence, and while it may have been applied recklessly by some writers, it has fully justified itself. The rich deposits at Cobalt have afforded subject for dispute, and we note with interest the debate that occurred at Toronto recently. Mr. Hixon held his lance against no less an authority than Mr. C. R. Van Hise, and while he stood in a position of lonely splendor on that particular occasion, we venture to believe that his ideas, as expressed then and now, will find support among mining geologists. The tendency is to restrict the sphere of secondary deposition, to credit ascending waters with greater ability to form bonanzas, and to recognize that thermal waters are largely of magmatic origin.

In a recent suggestive contribution to this journal, Mr. James F. Kemp, of Columbia University, touched upon this matter in his usual informing way. Referring to the most remarkable of concentrations by secondary enrichment, namely, the chalcocite orebodies of Butte, the Professor quoted the suggestion that these deposits are due to uprising solutions of copper, set in motion by thermal activity associated with the late intrusion of rhyolite. It appears likely that the deposition of copper is the last notable act of the ascending solutions, rather than one of the results of descending surface waters. The occurrence of copper below zones rich in other metals, and far too deep for the penetration of the ground-water, justifies a restricted application of former theories. At Butte, despite the shattered condition of the country, consequent upon three or four successive periods of fracturing, the chalcocite has been found from 1,000 to 2,000 feet below the possible bottom of the ground-water, so that it is wholly unlikely that solutions enriched at the expense of the upper parts of the lodes could have been responsible for the orebodies of the deep levels. Moreover, at Mt. Morgan, in Queensland, and at Bingham, in Utah, copper sulphides have been found in notable quantity underneath bodies of ore rich in other metals, but barren of copper when exploited near the surface and for several hundred feet below it. In these cases, it is not at the base of the oxidized zone or near the bottom of the ground-water that the copper has been found, but at a depth apparently beyond the reach of superficial agencies and within the domain of the uprising solutions, to which, at another time and under different conditions, the ore deposits owe their primary origin. We are thoroughly of the opinion that Professor Van Hise and other authorities have paid too little attention to the comparative shallowness of the ground-water, which does not extend indefinitely downward from its well-recognized upper level, but is really a thin blanket of water, three or four hundred feet thick. It is artificially depressed by mining operations, and it is tapped by the lateral workings in the upper portion of a mine so as to drain into the shaft. Miners know what it means to "take up" the water at the 700 or 800-ft. level, and they know that by the use of dams and pumps they can keep the bottom of their mine dry. That is because they are below the zone of ground-water.

At Cobalt there is a practical interest in this problem of economic geology, and we hope that the engineers in charge of operations will collect some useful facts. In regard to Mr. Hixon's reference to carbonaceous matter as a precipitant, this is a subject that the present writer studied with keen interest several years ago, notably at Rico, in Colorado; there the gold and silver veins are rich only while traversing shale, limestone, and sandstone where these rocks are blackened by carbonaceous matter. However attractive the theory, it must be applied with hesitation, for of this we are sure, namely, that while the solvents for gold are few and sparingly distributed, the precipitants are many and everywhere obtainable. In the case of silver, the solvents are more numerous, and the solution of the sulphide by surface waters is chemically reasonable, but even in this case a precipitant seems to lurk at every turn, and we need not lay stress on any particular one. We agree with Mr. Hixon, however, that the association of gold and silver with carbonaceous matter is a coincidence too frequent not to have a relation. In some cases the carbon may be an accessory after the fact, as indicative of hydrocarbon gases, or it may have been indirectly responsible by precipitating iron sulphide from sulphate waters, the iron sulphide becoming the immediate agent in the precipitation of the precious metals. It is a fascinating subject, and we hope that some of our mining geologists will give their testimony, to the end that all of us may learn something more.

Personal.

GEORGE W. MAYNARD is on his way to the Yukon.

F. L. BOSQUI has returned from Kirkland, Arizona.

C. C. BURGER has returned to New York from Nevada.

HORACE V. WINCHELL is at Butte, on professional work.

A. F. WUENSCH has returned to Denver from Mackay, Idaho.

JAMES W. NEILL is examining mines near Congress, Arizona.

E. A. H. TAYS left San Francisco for Tucson, Arizona, on May 6.

J. W. MERCER is at Los Angeles. He is expected in San Francisco.

J. POWER HUTCHINS has returned to New York from Dutch Guiana.

LOUIS S. NOBLE has been examining mines in Mohave county, Arizona.

HOWARD D. SMITH has been at Oroville investigating dredging ground.

S. H. BROKUNIER has been examining the oilfields of the Indian Territory.

W. H LINNEY, formerly superintendent of the Nipissing mines, is in New York.

PAUL JOHNSON was in San Francisco on his way from Vancouver to Reno, Nevada.

J. H. MACKENZIE is examing mining property near Ione, in Amador county, California.

L. M. COCKERELL is manager for the San Cayetano Mines, Ltd., at Guanajuato, Mexico.

FRED. G. FARISH sailed on the 8th inst. from New York for Amsterdam, on professional business.

S. F. PARRISH has opened an office at Tonopah, Nevada, having moved thither from Los Angeles.

LUCIUS J. BOYD is now general manager for the Chase-Andrews Concentrating Co., at Lovelock, Nevada.

J. PARKE CHANNING has been elected president of the Alumni Association of the Columbia School of Mines.

EDWIN C. HOLDEN has joined the firm of Hill & Irvine, which will be known henceforth as Hill, Holden & Irvine.

H. E. WEST is in London, but he expects to return to the Spassky copper mines, in Siberia, within a few weeks.

H. S. MUNROE and JOHN J. ROBERTSON are leaving Parral, Mexico, to go to the Argentine, in South America.

EDMUND JUESSEN has an office in the McCornick Block at Salt Lake City. He is now examining mines in California.

W. L. COBB has returned to Sausalito, Cal., from examining mines in San Bernardino county, in behalf of French capitalists.

CHARLES HARRIS has left Colorado for British Columbia where he has been engaged by a large placer mining company at Atlin.

C. C. LEAVITT, JR., has resigned as superintendent of the Copper King mine, at Fresno, to become general manager for the Fresno Copper Co., Ltd., of Glasgow.

F. F. WEBER, reeently superintendent of the New Almaden quicksilver mine at New Almaden, in Santa Clara county, California, passed through San Francisco this week on the way to Benson, Arizona, to inspect some properties.

T. B. BASSETT, for the past two years general manager of the Belen Mining Co., at Cumpas, Sonora, Mexico, resigns his position to devote more time to other branches of his profession, resignation to take effect during the month of June.

B. C. SHIPMAN, for eight years with the Westinghouse company as erecting engineer of high-tension plants, has opened an office in the Atlas Bdg., San Francisco, where he can be consulted on mining and transmission power lines and kindred subjects.

Mining Summary.

ALASKA.

Reports from Ketchikan indicate that the reorganization and sale of the properties of the Alaska Copper Co., at Coppermount, on the west coast of Prince of Wales island, was not concluded. The mine and smelter have been closed for several months awaiting the consummation of negotiations with capitalists at Duluth, Minnesota. At one time it was announced that the deal was closed, but it now looks as though it had been called off indefinitely.——The Hydah mine will soon ship to the Hadley smelter, as the tramway and bins are ready for use. The tramway is 2,000 ft. long, connecting the beach and the big open-cut where the orebody has been opened for a width of 40 ft.——The Hadley furnaces have been blown in again.——Work will be resumed at once at the Moonshine, at Cholmondeley sound. ——Sinking in the main shaft of the Red Wing mine at Copper City is still in progress, and it will be continued 80 ft. more, to the 200-ft. level, where driving will start.

ARIZONA.

GILA COUNTY.

Many companies have been handicapped on account of delays in delivering machinery at Globe, but new hoists have arrived for the Superior & Boston, Calumet & Globe, and Globe-Arizona properties. The ore shipments from the various properties continue to be large, and, although the Old Dominion plant is unable to treat custom ores, it is still receiving all shipments. Four furnaces are running, and, with the exception of some low-grade sulphides from Cananea, all the ore being smelted is from the company's own mines. The sulphide stope on the 14th level is supplying a large tonnage, as is also the west stope on the 9th level. Connections are being made to open the Kirky vein on the 11th and 12th levels, and a drift will be run to open it on the 14th level. No. 4 cross-cut on the 14th level has been started, and should reach No. 1 vein by the end of this month. The station on the 14th level has been cut, and the head-frame for the electric hoist is being erected. B shaft is now almost down to the 11th level and the connection with A shaft on the 10th level will be made this month. The construction work at the Old Dominion is progressing well, but the delay in the arrival of structural steel for the extension of the smelter building may retard the erection of No. 5 furnace. No. 1 converter-stand is being moved to make room for the new furnace. Coke is coming in more rapidly, and there are now 150 cars between Bowie and Globe.——The Arizona Commercial properties are maintaining regular shipments of sulphide ore from the Copper Hill mine to the Old Dominion smelter, and are also sending to the smelter some iron ore carrying copper and a little silver. Shipments of silicious ore are being made to Douglas. Pumps have been installed in the Black Hawk shaft, and sinking has been resumed. By the first of June the inclined shaft will be 600 ft. deep.——At the Great Eastern shaft of the Superior & Boston company, a cross-cut is being run to the south on the 160-ft. level, and the north cross-cut is being continued to intersect a small vein. The Limestone shaft is down 124 ft. and a level will be driven from the 118-ft. point.

PINAL COUNTY.

(Special Correspondence).—J. W. Sharpe, who has taken a working bond on the George Westfall group of copper claims, situated in the Red Hills district, east of Florence, is pushing development work with a force of miners, with George Westfall as foreman. A new prospect shaft was started, and it is nearly 100 ft. deep. This shaft is well situated, and is yielding some rich ore, consisting of copper carbonates, and oxide, and chalcocite.—— The Ray and Gila copper companies have ordered a number of hoisting engines to be placed on their 2,000 acres of mineral ground at, and surrounding, Ray. When all of these hoists are in operation, Ray will be a lively mining camp, and a new and important chapter in the history of the county's mining industry will begin. The companies above named have also asked for bids for the construction of a standard-gauge railroad from Kelvin to Ray, distant seven miles, and this road will be completed at the earliest possible date.—— The Alta Mining Co., at Mineral Hill, is sinking a double-compartment shaft on the dike backing the White carbonate lode. The shaft is about 80 ft. deep, and in the bottom there is a good grade of copper ore, consisting of oxides, glance, and silicates, carrying iron, and some silver. The inclination of the shaft, which follows the dip of the dike, is about 65°. As soon as a depth of 100 ft. is reached in this shaft, a cross-cut to the west will be driven to determine the width of the vein. A new steam-hoist for this shaft, also an air-compressor, and machine-drills, are now on the way from San Francisco.

Phoenix, May 6.

YAVAPAI COUNTY.

Deeds for 62 tracts of placer property have been filed by the Arizona Con. Development Co. This company was formed a year ago to take over 2,500 acres in the Castle Creek, Agua Fria, and Tip Top mining districts, and plans to operate dredges on a large scale. H. W. Hamilton is president, and several Chicago men are interested.

CALIFORNIA.

PLACER COUNTY.

Men are needed in the mining districts of this county. At the Herman mine, as soon as the season opens, 120 men will be employed at the mine and mill and in construction

Map of the New Mining Districts of Nevada and California.

work.——About 10 men are working on the Home Ticket channel.——A tunnel is being driven to open the lower end of the channel, at El Dorado mine.——A big cave has closed the mouth of the tunnel at the Big Basin property, and no work is being done.——At the Glenn mine, above Bald Mtn., Robert Jones is running a bedrock tunnel.——The Eclipse mine is pumped out to the 400-ft. level, at which point a drift will be run to the east.——About 30 men are employed at the Three Stars, and the shaft is down 1,200 ft. Stoping will soon start.

SIERRA COUNTY.

(Special Correspondence).—The Brandy City Mining Co. has the wagon bridge at Indian Valley nearly completed and will soon put on a large force of men to complete it from that place to the mine.——John Costa has started a raise from the face of the lower adit at the White Bear, to strike the Excelsior channel.——The Telegraph company is preparing to re-build the mill that the snowslide struck last winter.——C. J. York is running the new mill at the

Downieville foundry, on ore from the Mexican mine.—— The mill at the Papoose will be ready to start on May 10. ——Buckingham & Girard are preparing to start their mill on the Elsey mine.——The Sovereign has a crew of 12 men at work completing the road that was begun last fall to connect the mine with Sierra City.——At the Sierra Buttes they have hung up the 40-stamp mill on account of a breakage of the tram rope. A new rope is on the way and the mill will start as soon as it is installed. They are running the 20-stamp at No. 7.——The Hoyse Consolidated Co. has resumed work on the new mill and will have it ready to run about August 1.

Downieville, May 3.

TUOLUMNE COUNTY.

(Special Correspondence).—Another rich strike has just been made at the Soulsby mine, this time on the 600-ft. level. Work has been in progress on this level for a long time without any success, and it was not until the original plans were abandoned and a new course taken that the rich shoot was found. Recently a valuable strike was made on the 200-ft. level. From the workings of the Davidson shaft a cross-cut is being driven at a depth of 500 ft. to tap the Wheal Perrin vein, about 350 ft. distant. A crew of 75 men is at present employed at the Soulsby.—— Work of erecting a 10-stamp mill at the Garfield mine, the property of the Floyd M. Co., near Tuolumne, will be commenced this week. The mill, hoist, and compressor will be operated by water-power. It is believed that the property will be equipped with all necessary machinery, and in active operation by July 15.—— A body of good-grade ore has been uncovered in the south drift of the 200 level at the North Star mine. The rock shows free gold, and it is believed the body of ore is a large one.—— Extensive preparations are being made for operating the Ellen Winton mine. The stamp-mill will soon be under construction, and a boarding-house and other buildings are nearing completion.—— The Kanaka mine will be in active operation soon. The manager, Samuel Harris, of San Francisco, arrived last week, and will hasten the work of equipping the property with some new machinery, and of erecting necessary buildings. There is said to be ample capital for the contemplated improvements and development of the mine.—— A new body of high-grade ore has been found at the Mohican, southeast of Tuolumne. The strike was made in an adit being driven above the old one. The vein is three feet wide. It is understood that the crew of four men will soon be increased, and that the mill will be in operation.——The Spring Gulch mine, southeast of Tuolumne, is being unwatered for the purpose of inspection by prospective buyers.—— A rich shoot of ore was uncovered a few days ago in the Blue Lead mine, near Arastraville, after extending the adit only two feet from the point where the former operators ceased work. The property is being worked under bond by R. W. Roberts, R. H. Rowe, and W. Fowles, who have already extracted 15 tons of the newly found ore, which they say will go $100 per ton.—— The strike recently made below the 1,800-ft. level in the Eagle-Shawmut mine, at Jacksonville, is said to surpass all previous strikes at that property. Simon Goudge has superseded James Riley as foreman.—— Sinking is the principal work in progress at the Clio mine, and the shaft is rapidly increasing in depth.—— The Imperial mine, recently bonded to San Diego people, will be equipped with a mill in the near future. Sinking is now in progress.

Tuolumne, May 6.

COLORADO.

GILPIN COUNTY.

The quarterly report of the Pewabic company states that the Pewabic shaft has reached a depth of 700 ft., at which point sinking was stopped on account of a very heavy flow of water. Drifts have been driven from this point east and west. The development work done consists in 830 ft. of driving, 35 ft. of sinking, and 460 ft. of raising, during the quarter.——The Ipava shaft of the Lotus group in Russell gulch, which is owned by the Sternberger Bros., is being sunk. It is already 175 ft. deep, and good ore has been opened. Connections are to be made with the Columbus workings, and thus the Ipava workings will eventually be connected with the Lotus. Fred Wood is in charge of operations.——About 25 lessees are at work on the East Notaway property of the Town Topics Gold Mining Co. Martin & Co. have opened the ore-shoot in the 655-ft. level on the west side of the shaft, and are shipping copper ore.

PITKIN COUNTY.

A deep tunnel is being planned to open and drain some of the old producers to Aspen. D. R. C. Brown and Charles J. Hughes are interested in the project and it is planned to expend one million dollars in the work.——A group of Michigan capitalists is interested in the Sandy Hook Mining Co., operating on Ohio creek, near the old Chronicle property. A tunnel will be run to develop the property.

SAN JUAN COUNTY.

The Bagily tunnel is in nearly 4,000 ft. and 10 ft. per day is being made toward the Mineral Point country. The electric drills have been discarded and Sullivan sluggers are doing the work.——The mill of the Hercules Consolidated company has started with a capacity of 150 tons per day. A large ore reserve has been blocked out in the four miles of tunnels and drifts.——The new machinery installed in the Hamlet mill is working satisfactorily and the mill is handling 75 tons of ore per day. There are four tunnels on the property.——The Mogul mill at Gladstone is still idle, on account of delay in the delivery of machinery.——The lower tunnel at the Auburn property, on Tower Mtn., is in 800 ft. and will be continued 1,[illegible] ft. farther. A power-line will be built to the Animas Power Co.'s line, and the compressor will be run by electricity.——The [illegible]ing Co.'s Champion property, on Sultan Mtn. [illegible]g well. A shaft has been started in the lower level to connect with the tunnel that is being run from [illegible] the Animas river, a distance of 500 ft. This company's Silver Wing mine, above Eureka, shipped eight cars of high-grade ore to the Ross smelter at Silverton, last month.

SUMMIT COUNTY.

(Special Correspondence).—The Stearns-Rogers Mfg. Co. recently shipped two cars of machinery from their Denver warehouse to the King Solomon T. & D. Co. for the new power-plant of that company. The machinery consists of an Ingersoll-Sergeant compressor built to operate at an elevation of 10,000 ft., with compound air and steam cylinders; a receiver 4 by 16 ft.; a 100-ft. smoke-stack, together with pipes, valves, and connections, etc., necessary for the complete setting of the plant. Several days ago the same company shipped from an Eastern warehouse a 163-h.p. Heine water-tube boiler. F. C. Dinsmore has been at the mine for the last 10 days making preparations to install this machinery as soon as it should arrive. The concrete foundations are in place and three cars of lumber, brick, and cement have been unloaded at the plant. The power-house is being enlarged and new coal-sheds built. No money is being spared to make this plant the most efficient, modern, and up-to-date in the district. This mine has been one of the most active in Summit county for the last two years. Operations have been continuous day and night and the cross-cut tunnel has been advanced to the 1,400-ft. mark. Having now reached the point where the former power-plant was inadequate to do the work at the greatest possible speed combined with economy, it was voted at a directors' meeting to install the above-described plant as early as possible in the spring.——As soon as the new plant is ready for operation, two 3½-in. drills will be put in the breast of the tunnel and the big bore advanced with all possible speed. This company owns extensive properties situated in the Ten Mile range near Frisco. These properties are being developed by a big cross-cut tunnel which enters the mountain about a mile up the Ten Mile cañon from Frisco, and a little above the tracks of the C. & S. railroad. At this point depth is gained rapidly until at the steepest point a depth of over half a mile is gained. Already six veins, carrying gold, silver, and copper, have been opened.

Denver, May 4.

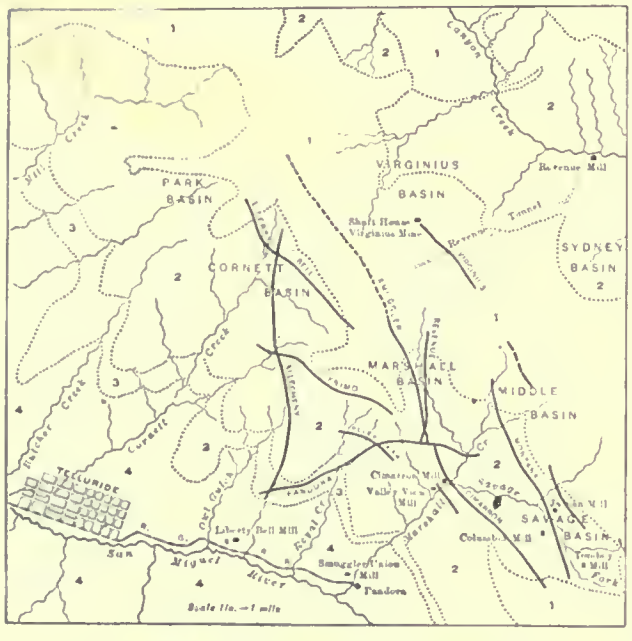
IDAHO.

BLAINE COUNTY.

The mining outlook in the vicinity of Hailey is more promising than ever before. The Idaho Consolidated company, which has added the Minnie Moore to its holdings on the galena belt, is equipping its properties with electrical machinery, and preparing to start the mill working on the old tailing dump. A shaft is being sunk on the property and the company should be on a solidly producing basis within a few months.——The Croesus has again resumed shipments and has developed ore carrying gold, silver, copper, and lead.——The Ophir, Bullion, Mayflower, Fraction, and Jay Gould properties will be re-opened by Tustin & George. They will be tapped by an extension of the Durango tunnel.——The Eureka mill is expected to produce concentrate without interruption.——A good body of ore has been developed on the Red Elephant group of the Quincy Junior company, which will keep the mill running indefinitely. ——The Nay Aug, on Deer creek, has developed good shipping ore, in addition to second-class ore.

OWYHEE COUNTY.

The Burgh mine, near Rooster Comb, 15 miles from Silver City, is said to be looking well, and the five-stamp mill is running continuously.——A strike is reported in the Miller & Walter mine on Florida Mtn.——At the Potosi mine, development continues on the No. 2 level, both in the south drift, which is now in 230-ft., and in the raise north of the Knickerbocker shaft, which is up about 30 feet.



Sketch Map of Telluride District, Colorado.

SHOSHONE COUNTY.

(Special Correspondence).—Five mines, operated by the Federal M. & S. Co. in the Coeur d'Alene, netted profits of $2,685,213.76 in 1906, according to a statement filed with the assessor of this county. Improvements made at the properties, the Standard and Mammouth at Mace, the Morning at Mullan, the Last Chance at Wardner and the Tiger-Poorman at Burke, cost $118,873.82. The gross tonnage extracted was 933,557, yielding a gross value of $7,775,770, from which is deducted the cost of production, $2,755,867.75, and cost of transportation and reduction, $2,215,814.67. The Standard was the largest producer, the tonnage being 334,403, yielding $3,969,941.46 gross or a net profit of $1,912,575.92; the Last Chance produced 168,608 tons, $680,874.70 gross or $80,439.10 net profit, while the Morning shows 313,070 tons, $1,651,441.44 gross or $255,237.78 net profit. The statement shows substantial increases over 1905, when the total number of tons of ore extracted from all the Federal mines amounted to 905,004, yielding $5,962,385.59. The cost of the extraction of the ore amounted to $2,357,497.62; reduction and transportation, $1,950,421.17; improvements, $89,248.47, leaving net profits of $1,565,218.33.——Work has been resumed upon the Gettysburg-Independence mine at Mullan, where Kennedy Hanley, the owner, has let a contract to drive the cross-cut tunnel 600 ft. farther to encounter the Morning vein. The mine has been idle four years. Mr. Hanley has expended $70,000 in buying outstanding titles to nine claims comprising the group, in the last four months. He has also spent $60,000 in developing the property, and has installed a compressor and a motor, operated with power from Spokane. The tunnel has been extended to 1,400 ft. When the vein in the Morning is encountered in the Hanley property it will be of a depth of between 700 and 800 ft. In the Federal property the vein has been opened at a depth of 2,000 ft. It is figured that it will require three months' work before the ore-shoot is encountered. C. B. Boyden is superintendent of the mine. ——Through J. A. Jackson, representing capitalists at Denver, Colo., an offer of six cents per share has been made for the control of the Crater and Big Medicine groups, silver-lead propertios, in the Coeur d'Alene. Each of the groups is capitalized for 1,500,000 shares. It is the intention of the Denver men, if they acquire the control of the properties, to consolidate them upon the basis of share for share. If the deal is consummated, approximately $100,000 will be paid for the control of the two groups. The Big Medicine group adjoins the Cedar Creek properties, while the Crater adjoins the Big Medicine, the C. & R., the Happy Day, the Majestic and the Phoenix. Neither group has been developed, but the surface showings of both are said to be excellent. A contract was recently let for a tunnel on the Crater.—— The Oom Paul Con. Mining Co. and the owners of the Lady Bell mining claims have consolidated with increased capital, at Wallace. The new company is capitalized for $1,600,000, the incorporators being: F. C. Richardson and F. H. Richardson of Burke, P. F. Smith and James F. McCarthy of Wallace and Walter McKay of Portland. The Oom Paul company is the owner of the Williams, Day, Western, McComas, Caribou, Forget-Me-Not, Portland, Snowshoe, and Evening Star claims. The Lady Bell claim was until recently owned by Richard Wilson and Walter McKay of Portland, and James Leonard, George W. Ruggles, and James F. McCarthy of Wallace. The Lady Bell claim has been paid for in stock of the new corporation. It is believed that the Oom Paul ore-shoot crosses the claim. ——A. Herman, president of the East Snowstorm Mining Co., reports that the No. 2 tunnel is in 240 ft. At 200 ft., a cross-cut was driven for 31 ft., showing vein matter along the wall. The hanging wall has not yet been encountered.—— F. A. Heinze, who recently acquired extensive mining interests in the Coeur d'Alene, is figuring upon the purchase of the O. K. Consolidated, the Black Hawk, and the Wyoming groups, which adjoin the ground of the Coeur d'Alene D Co., which is under bond to him.——Directors of the Merrimac Mining Co. at Wallace elected these officers: President, W. W. Woods; secretary and treasurer, Charles H. Bell. C. H. Bell was appointed manager for the company. The company was recently incorporated with the object of developing seven claims on the Polaris and Big Creek gulches in the Evolution mining district and adjoining the properties of the Polaris and Yankee mining companies. Buildings will be erected and a force of men set at work in a short time.

Spokane, May 4.

MONTANA.

GRANT COUNTY.

The old St. Louis & Montana company, which became the Goodhope company, has been reorganized a second time, under the name of the Hope Mining Co. The property owned by the company has been operated since 1867, and has yielded good dividends. An air-compressor is now being installed at the mine and power-drills will be used in all the principal workings.——At the property owned by George S. Congdon and Frank M. Kent, near Lookout Mtn. on Rock creek, the tunnel is in over 1,300 ft., and the vein will soon be cut.——The Mountain Ram group of claims, 12 miles southwest of Philipsburg, has been sold to men at Colorado Springs. A 100-ton cyanide plant will be erected. ——An option on 45% of the stock of the Twin Buttes company has been given to Eastern people.

NEVADA.

WHITE PINE COUNTY.

The railroad that will carry ore from the Alpha shaft of the Giroux Consolidated Co. to the concentrator at Kimberley is about completed. A large force of men is working on the big fill, back of the Morris shaft, which will complete the work. The concentrator is nearly finished, the walls are up and the roof about done.——The Biscuit company is loading cars with silver ore from the Tea Cup mine at Cherry Creek.——A copper strike is reported in the Joe Moore shaft at Dolly Varden, at a depth of 115 ft.——Two steam-shovels are working on the foundation excavation for the concentrator at McGill, a third is on the ground, and a fourth is expected to arrive in a few days.——A churn-drill has been put to work on the Veteran claim of the Cumberland-Ely company.——The Chief of the Hills property in the Cherry Creek district has been sold by F. M. McDermid to J. W. Walker and Alfred Fletcher. The purchasers agree to sink a 700-ft. shaft at once, and a 40-h.p. gasoline hoist will be installed.——The Ely Consolidated company has ordered a 25-h.p. hoist for the Brilliant shaft. The small hoist now at the Brilliant will be transferred to the Famous claim, where a new shaft has been started.

OREGON.

BAKER COUNTY.

The Daines M. & M. Co. of Spokane, operating in the Greenhorn camp of eastern Oregon, has started mills on two properties. Two new mills will be installed this year. One of these, a 10-stamp mill, will be hauled into the camp soon. The other will be running before the season is over. ——Miners working on the long tunnel from the shaft of the Midway, in the Golconda district in eastern Oregon, at 300-ft. depth, broke into the main vein for which they were driving, at a point 271 ft. from where they started. They have since cut through it and find it 10 ft. wide.

GRANT COUNTY.

Shareholders of the North American Copper Co. have recently visited the property. This company has made final payment upon the Nelly Bly property, upon which sinking has progressed to a depth of 50 ft. The shaft of the Snake mine has been re-opened to the 500-ft. level, and retimbering is being done.——A good strike is reported in the Burro Mtn. district, on the property of the Burro Mountain Copper Co., at Leopold. This company drove 200 ft. and then started a cross-cut, which is now 150 ft. long and shows good sulphide ore.

LANE COUNTY.

The Oregon Securities Co.'s properties, which have been in litigation for some time, have been sold at auction to John W. Wheeler for $100,000. A new company will be organized, and the properties operated.——The sale of the Grizzly mine in Bohemia, to an English company, is being negotiated.

SOUTH DAKOTA.

CUSTER COUNTY.

(Special Correspondence).—The Clara Belle Mining Co. is working a full force on the 250-ft. level in the new shaft, and is driving east to catch the orebody that was left in the old inclined shaft. Frank Hebert, the superintendent, says that although they have cut through a large body of good milling ore, it is not the vein of high-grade quartz that they were seeking.——The Old Bullion mine has been bonded to A. R. Roosevelt of New York and a mill will probably be erected during the summer. The mine is fairly well developed with one adit 400 ft. and another 200 ft. in the mountain, while a shaft has been sunk from the apex to a depth of 200 ft. These openings are all in the vein, which carries sulphides and is represented to be very wide The ore averages $6 per ton in gold, and is amenable to the cyanide process. The option was secured through Sam Boylson of Keystone, where the mine is situated.——The difficulty which has existed for several weeks past between the Holy Terror Keystone Co. and C. F. Collins, the former superintendent, has been settled, by Mr. Collins surrendering the books and list of stockholders to the attorney for the company, W. A. Babson. It is announced that the Holy Terror mill will now be put in order and started up May 10.——The Crown mine, situated in the Hornblende district west of Rochford, has been sold to an Eastern syndicate that will immediately start work. This property belonged to James McNickle and has always been represented as a free-milling proposition.——The Golden West mine, also in the Hornblende district, is running steadily with two eight-hour shifts; the showing on the plates is excellent, and there is a large vein.——The Ideal Mining Co., whose ground is situated about seven miles northeast from Custer, is running an adit into the mountain to strike the vein which was exposed at the surface. They are also grading a wagon-road and excavating for foundations for the new air-compressor which is on the ground. A. Conover is in charge.——The mining camps in the Southern Black Hills have never looked more prosperous than they do at present, and everyone looks forward to a profitable season.

Custer, May 3.

WASHINGTON.

CHELAN COUNTY.

(Special Correspondence).—A stampede to Chelan Butte and the location of a number of claims have resulted from the discovery of goldbearing quartz.

Republic, May 3.

FERRY COUNTY.

(Special Correspondence).—The Blue Bell-Belcher Mining Co. has appointed Wm. Woodward superintendent, and will resume work immediately on an adit, now in 110 ft., and drive it to cut the northerly extension of the Belcher vein in its own ground, at a probable farther distance of 100 ft. The ore is iron sulphide; it carries gold, and shows indications of copper.

Republic, May 3.

SPOKANE COUNTY.

(Special Correspondence).—Spokane newspapers having reported the discovery of tin ore on Moran prairie, six miles east of Spokane city limits, in which R. Marsh, Charles P. Robbins, and Charles Theis are interested, your correspondent wrote Mr. Robbins, formerly of Eureka, Nevada, for information. He replied, sending specimens of tin oxide, in quartz gangue, with the following information: "Last May the Spokane newspapers reported that Dayton Stewart had found a lead mine on Moran prairie, and he and Mr. Marsh went to the designated place and found float in a gulch, which the former, a Spokane assayer, tested, and found the rock contained tin. They tried to negotiate for an interest, but were unsuccessful. Mr. Stewart bonded his claims to Patrick Clark, who had some work done, but the result was not satisfactory, and the bond was thrown up. Messrs. Marsh, Robbins, and Theis subsequently acquired title to the ground, and bonded adjoining property. The claims are on patented land, in the midst of orchards. From the description given, they are situated on a zone of greisen and granitic schist, with metallic ores cropping out in places. The present owners, about March 1, began exploiting the ground, and are employing seven men. Very little is known at present as to the vein system, but the ore-bearing strata strike up a hillside, the apex of which is about 200 ft. above the track of the Spokane & Inland Electric railway. The zone referred to is 750 ft. long and 500 ft. wide. What have been regarded as the veins are from 10 to 50 ft. wide, and trend northeast-southwest. On the most westerly stratum of ore an open-cut has been driven 50 ft., with the face 20 ft. deep. Other prospecting work is being done on smaller streaks. Along the last 25 ft. the ore will concentrate to 10%. The face of the cut was eight feet wide in good ore. The concentrate will yield 70% tin. On the hanging-wall side of the pay-streak is lower-grade mineral, and on the foot-wall is a six-inch streak of wolframite and scheelite. I have been told that the discovery of tin ore on Moran prairie was reported 20 years ago, and a great excitement was caused in Walla Walla county, in the southern part of Washington, when the discovery of tin ore on what was known as the Mill creek slopes, 12 miles east of the town of Walla Walla, was reported, and a number of people rushed to the slopes and staked claims, but no development work was done."

Republic, May 3.

BRITISH COLUMBIA.

The trouble with the coal miners of western British Columbia and Alberta curtailed the production of ore in British Columbia for the week ending April 27. During that week the following is the tonnage of the ore shipped from the Rossland mines: Centre Star, 1,020; Le Roi, 1,785; Le Roi No. 2, 350; and White Bear, 70 tons of ore.——The main shaft of the Centre Star is now 100 ft. below the 14th level, and work in it has stopped until skips and track have been moved down to that level from the No. 12 level. Develop- [illegible] is making good progress, and [illegible] tre Star gulch into the Idaho [illegible] tation of the new hoist at the [illegible] as rapidly as possible, and it [illegible] 15.——The new machinery [illegible] and Empire soon, and prepa- [illegible] omplete.——Only 963 tons of [illegible] ek at the Trail smelter. Be- [illegible] Rossland mines, other ship- [illegible] Phœnix, 847; St. Eugene, [illegible] 22; Providence, Phœnix, 27; [illegible] 50; Iron Mask, Kamloops,

Map of Part of British Columbia.

33; Silver King, Nelson, 41; Last Chance, 20 tons of ore.—— The Northport smelter continues to operate on Le Roi ore. A fair supply of coke is on hand, and the plant can be kept in operation until shipments of fuel are resumed from the Crow's Nest Coal Co.'s ovens.

The Boundary shipments for the week ending April 27 were as follows: To Granby smelter, from Granby mines, 14,449; to B. C. Copper Co.'s smelter from Mother Lode, 6,640; from Morrison, 60; from Snowshoe, 3,970; from Emma, 220 tons of ore. To Dominion Copper Co.'s smelter, from Brooklyn, 96; from Sunset, 256; from Mountain Rose, 32 tons of ore. Total shipments for the week, 25,723. The Boundary smelters treated ore as follows: Granby, 15,003; B. C. Copper Co.'s plant, 9,355; Dominion Copper Co.'s plant, 384 tons. Total treatment for the week, 24,742 tons of ore.——The Fernie coal miners and operators have drawn up an agreement to cover a period of two years. This means the immediate resumption of work in the district.

MEXICO.

GUERRERO.

(Special Correspondence).—The Mitchell Mining Co. has just been advised that an additional shipment of 500,000 ft. of ties and timber has left Seattle, consigned to La Dicha & Pacific railroad at Port Marques, on the Pacific Coast, Mexico. All the rails for the railroad at La Dicha will go forward on a fast steampship from Belgium on or about May 4. The work will be pushed with all possible speed looking to the completion of the road from the mines to the coast, this fall. George Mitchell, president of the company, announces that the contract has been given out for three locomotives and a large number of cars. One locomotive and fifteen cars have been ordered to be shipped at once from San Francisco, to be used on the construction work About 850 men are at work grading at the coast end of the line.

JALISCO.

The United States consul-general at Mexico City estimates that in the last four years $125,000,000 of American capital has been invested in mines in Mexico. Guanajuato leads with $12,000,000 and Jalisco and Oaxaca are next with $10,000,000 each.——Machinery for the old Cuartas mines in Bautista camp of Jalisco, has been shipped from the States and will reach Ameca early in May. The equipment includes a four-drill compressor, a steam-hoist with a capacity of 800 ft. in depth, and a Cameron sinker with a capacity of 250 gal. per min. This company is a Chicago organization, with Harry M. McIntosh president and William A. Lees general manager.——A bonanza shoot has been opened in the property of Los Reyes Mining Co., of Guadalajara.——It is reported from Ezatlán that 17 ft. of rich ore has been struck on the 1,050-ft. level of the Amparo mine.——The Makeever Brothers have just closed a deal to re-open the Real Alto and San Sebastian camps of Jalisco. The old Tajo mine, has been purchased and options covering the other old mines have been secured. The plans include the erection of a hydro-electric plant to utilize the water of Los Reyes river, and the erection of a mill. These properties are two days' journey from San Marcos, the nearest railroad point. L. C. Malone will be in charge of the work.——The San Domingo Mining Co. has ordered the purchase of 100 mules to use in transporting high-grade ore from the mines to the Mexican Central station at Etzatlán. Rich strikes are reported in the Rayas and El Favor claims. Air-drilling machinery will be purchased at once for this property.——The boom in tin mining in the Paso de Sotos district of Jalisco, adjoining the State of Aguascalientes, has entirely subsided.——The Lupita mines in the Mascota district have been shut down. The manager, Patrick Fitzgerald, stated that it had been decided to stop mining and milling operations indefinitely. These mines have been steady producers for several years, and were regarded as important properties.

SONORA.

The new No. 2 furnace at Cananea has been blown in. The two new furnaces have a capacity equal to the combined capacity of six of the old furnaces that they replaced. Another new furnace will be finished in about six weeks.

NOVA SCOTIA.

(Special Correspondence).—During the last few months, so many enquiries have been made to the Government about Nova Scotia gold, iron, and coal mines, that the Government has decided at the request of many interested parties in the States, to have a first-class mineral exhibit at the Jamestown Exposition.——Not only are the foreign capitalists that have lately become interested in Nova Scotia mines urging the desirability of such an exhibit, but the local people are very much in favor of such an exhibition. There is ample material at hand from the numerous mines. There are in this Province some of the biggest bituminous coal mines in the world. In fact, the biggest unbroken vein of bituminous coal ever opened was opened in one of the Allan shafts of the Arcadie Coal Co. We have iron mines that are proving of great economic value. We have gold mines that have been proved.——The Londonderry and Torbrook mines will be well represented. The principal gold mines, such as Micmac, Boston & Richardson, and the dozens of other districts, will be well represented.—— There has been such a decided step forward in the scientific development of Nova Scotia mines that the Province is rapidly coming forward as a valuable mineral-producing section.

Bridgewater, April 30.

Special Correspondence.

London.

Cornish Consols.—Cheerful Meeting.—Sound Finance.—West Australian Companies. — Golden Horseshoe. — Great Fingall.—Ivanhoe.—Interesting Details of Accounts.—Shrinkage in Australian Mining Shares.

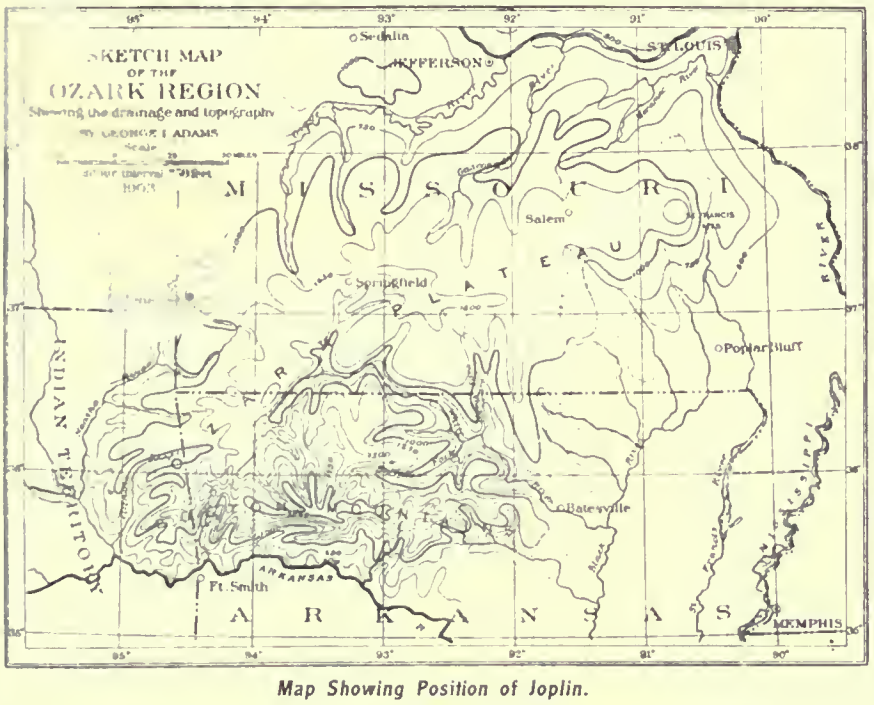
The report of the directors of Cornish Consolidated submitted at the first general meetiug was of a highly satisfactory nature. The Chairman accentuated its good points in a crisp and lucid speech of an inspiriting character, plainly showing that Cornish Consols lacks neither the means nor the ability for the establishment of a mining business on sound and at the same time up-to-date lines. This can be abundantly proved from whatever aspect the Company's doings and position may be considered. Take, for example, the manner of dealing with the accounts; the conservative policy of the directors is apparent in the fact that the charge for preliminary expenses—the outlay in the formation of the company, often spread over a considerable period—is entirely written off to the first year's revenue account. Then the valuation of the assets has been fixed in a way to preclude the risk of paying dividends out of capital. The Company holds a large number of shares in South Crofty; these are set out in the balance sheet at par, while the present market price is more than three times the nominal value. Speaking of this mine in his address, the Chairman described it as a splendid enterprise. Rapid progress has been made at South Crofty both at surface and underground. A modern battery of 40 stamps is well advanced in construction; the first 20 heads will start this month and the second 20 at the end of June. The Chairman said he thought it was not likely they would stop at 40 stamps; at the end of the year they would probably see 60 at South Crofty; and the question as to how soon they might have 80 stamps is only limited by the water-supply. The manager has committed himself to the extent of saying that he has five years ore ahead of his mill. Difficulties have arisen with the magnetic separation; but it will only be a week or two before matters are put right. South Phœnix, at Liskeard, is owned entirely by Cornish Consols. The mine is unwatered and the battery will be running early in the autumn. A plant is being put up by Cornish Consols at South Phœnix; to a certain extent they are making it an experimental mine; so that in their bigger mines they will avoid experimental working. Anything worth a good trial will be sent to the South Phœnix and most exhaustively tried; so that if the results are satisfactory the improved appliances will be employed at other mines. In addition to these investments Cornish Consols holds interests in several other mines, with some £25,000 cash in hand after paying dividends. Incidentally the labor question was touched upon at the meeting. It transpired that with about 1,000 men in their employ the managers have had no difficulty on that score, in spite of the rule, strictly enforced, of working full time, instead of 18 days in the month as customary in many of the other mines in Cornwall.

Three of the leading Western Australian gold mines have issued their annual reports for 1906. In the case of the Golden Horseshoe, after being debited with £25,703 for development expenses, with £23,708 for plant and machinery, and with £14,679 for income tax and Australian duty tax, the revenue account shows a balance of £248,816. To this has to be added £56,906 brought forward, making a total of £305,722. After certain adjustments, and £240,000 paid in respect of two dividends of 5s. and one dividend of 6s. per share, a balance is carried forward of £61,599. During the twelve months 237,294 tons (2,240 lb.) of ore have been sent to the mills, yielding 38,825 oz. fine gold, of a net value of £165,173. Of residue 34,632 tons have been treated by the cyanide process, yielding 11,996 oz. worth £51,126. Of slime 193,449 tons have been treated in the filter-presses, yielding £55,883 oz. worth £237,948. Of concentrate 4,239 tons have been treated by the roasters, yielding 12,660 oz. worth £53,919. Of residue 14,695 tons have been re-treated, yielding 2,714 oz. worth £11,520. Of sulphide ore and concentrate 9,714 tons were sold to the smelters, which realized £87,695. The total net value of bullion realized and in transit to December 31, 1906, amounted to £607,383. After treating 243,026 tons during the year, there were in sight at December 31 practically 1,000,000 tons of ore, valued at £2,889,944. The extraction (excluding gold from re-treatment of tailing) was 87.81% and the average value per ton £2.12.9. The total cost per ton, including mine development, shaft-sinking, and diamond-drilling, amounts to £1.8.10, as against £1.11.3 for 1905, which shows a reduction of nearly 2s. 6d. per ton.

According to the report of the general managers of the Great Fingall Consolidated, development work has been vigorously carried on during the year, a total of 8,230 ft. having been done. The main shaft is now 1,611 ft. deep. A large amount of exploratory work was done during the year. The total expenditure upon development was £39,037, the whole of which has been charged against revenue. The tonnage treated during the year was 249,646 tons, being an increase of 46,329 tons over the previous year, with the same number of stamps, such increase being chiefly due to the installation of the re-grinding plant. The power, air-compressor, and mill-plants have required some expansion during the year to provide for this increased tonnage. The 249,646 tons treated produced 121,502 oz. fine gold, having a value of £518,657. The working expenses, including development, averaged 19s. 11d. per ton, as compared with 19s. 9d. the previous year. After writing off £5,516 for depreciation of machinery, plant, etc., a net profit of £233,386 has been realized. This, with the balance of £125,699 brought forward from last year, made a total of £359,085, out of which sum four interim quarterly dividends have been paid, amounting in all to £275,000, leaving a balance of £84,085 at December 31. Out of this amount a further dividend was paid on January 10, 1907, amounting to £37,500, leaving a balance of £46,585 in hand.

The report of the Ivanhoe Gold Corporation for 1906 states that, after making provision for every description of expenditure, there is a profit of £259,281. Including the net balance from 1905 of £829, there is a total credit of £260,111. Interim dividends have absorbed £107,861, and the directors now recommend payment, on April 25, of a fourth and final dividend for 1906 of 9s. per share, (making 24s. per share, or £240,000 for the year). Directors' remuneration absorbs £1,350, and general reserve £10,000, leaving £6,511 to be carried forward. Further equipment has been provided during the year, and the expenditure thereon, amounting to £12,889, has been included in the ordinary monthly costs, and, with the expenditure on mine development, £42,224, making a total of £55,113, has been written off. The total expenditure on these items since the formation of the company, amounting to £692,428, stands in the balance sheet at £54,295, the amount of the company's original working capital. The working costs have been further

reduced during the year to 18s. 10d. per ton, while the total West Australian costs, including the entire expenditure on mine development, buildings, plant, and machinery, work out at 24s. 2d. per ton. The following shows the working costs per ton of 2,000 lb. during the last five years: 1902, £1 7s. 1d.; 1903, £1 3s. 4d.; 1904, £1 1s. 3d.; 1905, 19s. 5d.; 1906, 18s. 10d.; 1907 (first quarter), 17s. 8d. The total dividends distributed in the company's existence will, upon payment of the dividend now recommended, amount to £1,750,000. During the year 208,304 tons of ore were crushed, showing a duty of 5.9 tons per stamp, recovering gold to the value of £149,955, at a total cost of 8s. 1.87d. per ton. The increase in tonnage over 1905 is 11,735, and is mostly due to the additional quantity of water made available by a new pump. During the last three months of the year when this pump was running, the duty per stamp was 6.33 tons, through the usual punched screens. The schedule of ore reserves shows 932,551 tons, containing £... 39,838, an average of 54s. 5d., against 59s. 4d. per ton for 1905, the increase in tonnage being 163,491 tons.



Map Showing Position of Joplin.

No ore has been taken into reserves lower than the 1,371-ft. level, as, in the manager's opinion, the 1,519-ft. level has not been opened up sufficiently to justify an estimate.

Zinc Corporations and Lodden Valley, although slightly better, are still a weak market. Writing to a shareholder on April 11, the London secretary of the Zinc Corporation is reported to have said: "The directors feel confident as to the ultimate success of the company, and are advised that the question of the treatment of the tailing is absolutely solved by the Cattermole process. As soon as a fair run of tailing through this process has taken place, no doubt we shall be supplied with details as to the results being obtained." Commenting on the huge losses in market values of the 34 representative Australasian mines comprised in its monthly table of comparative values, the *Australasian World* says they cannot but be regarded as serious. Between March 11 and April 8 there was a gross shrinkage in values of £2,422,562 — a fact which is a severe reminder that the Australasian mining market is extremely sensitive. What occurred during the period to occasion such a serious fall is past history. The truth is that the American collapse depressed every department of the Stock Exchange.

Joplin, Missouri.

Shipments of Ore. — Market Weakening. — Discovery on Indian Land. — New Mills. — Granby Co.'s New Shaft. — Sale of Property. — Scarcity of Experienced Labor.

The highest price reported paid for zinc ore for the week ending April 20 and also for the week ending April 27 was $52 per ton; $82 per ton for lead ore was the high price for both weeks. The high price for zinc ore a year ago was $45 and for lead ore $78 per ton. The market seems to have a downward tendency and purchasing is easy for the agents.

Shipments	Zinc. Lb.	Lead. Lb.	Combined Value.
Week of April 20	12,259,980	1,962,900	$ 376,799
Week of April 27	12,187,660	1,963,460	366,441
Year to date	201,943,780	31,845,280	6,167,348
Last year	168,791,720	23,849,800	4,604,953
Increase	36,152,060	7,995,480	562,395

A drill on the Baxter Royalty Co.'s land, in the main street of the town of Quapaw, found a rich deposit of zinc ore from 138 to 151 ft. The town of Quapaw is named after John Quapaw, a former chief of the Indian tribe that owns the land. The well was drilled for the purpose of supplying water for the inhabitants, and the ore encountered is said to be the richest yet found in the many strikes made in that part of the Indian Territory.

The frame-work for the new 500-ton mill of the Deacon mine, owned by the Trinity Zinc, Lead, & Smelting Co., on the south end of the 120-acre lease in the Duenweg district, is up, and the work of completing it is being pushed as rapidly as possible. It is to be equipped with all the latest improvements in mill construction, making it first-class in every particular. Just across the road to the south of the Deacon mill, Mattes Bros., of Joplin, have just completed and started the big 500-ton San Gabriel mill.

For several years the Granby Mining & Smelting Co. has had drills at work over its land exploring the lower ore measures, never mined, and only within recent years known to exist. The company has selected a site where the heaviest portions of the lower ore vein is apparently massed, and will here sink a large shaft to test the drill-records of the surrounding holes. Care has been made in the selection of the site to avoid underground waterways, and the shaft is placed where no surface water will be drawn into it.

James Radley and Frank Blain, of Joplin, have been working a four-lot lease on the old Charter Oak, in the south edge of Carterville, for several months, and succeeded in opening up a splendid vein of ore in the sheet formation at a depth of 150 ft. They had a 12-ft. face of ore, and of good grade. Last week they disposed of the property to Judge Pfost, of Kansas City, for a neat figure, and a 200-ton mill will be erected at once.

The starting up of a number of new mills would seem to indicate an increased output; on the contrary, it is having the opposite effect. This is due to the division of good workmen. Hardly a mine or mill in the district is now equipped with a full force of experienced men. The starting of so many new mills has called some experienced men from other mines and mills, leaving them crippled, while the new mill, being only partly supplied with

experienced men, is incapable of doing full duty. A few operators are paying a big premium for experienced workmen, and these are making record runs, while many others have fallen down because they could not afford to meet the higher prices for labor, and their output is lessened, not because the mine is less productive, but because the higher price for experienced men has reached a prohibitive stage.

Butte, Montana.

B. B. Thayer Reports Favorably.—New Mining Companies.—Barnes-King Consolidation.—Davis-Daly Estates.—Deepening the Anaconda Shafts.—Good Results From Deepest Level.

B. B. Thayer, assistant to H. H. Rogers, president of the Amalgamated Copper Co., has made an examination of all the mines, smelters, and associated industries of the Amalgamated, North Butte, and Butte Coalition companies in Montana, and he reports them in excellent condition. He said: "I have examined all the mines and have found greater orebodies blocked out and conditions generally better than last year, or at any time in the past. All the ore is being hoisted from the Amalgamated mines that the Washoe and Great Falls smelters can treat. With increased smelter facilities it will be an easy matter to provide the ore. Shafts are being sunk and development is going on without interruption. In the Anaconda mine we shall soon begin stoping the enormous orebody struck on the 2,400-ft. level. The only ore so far taken from the lower level was removed while development work was in progress. It is an immense body. In the meantime the shaft of the Anaconda is being lowered and eventually we shall find out what we have at a still lower depth."

Two new mining companies have been organized and incorporated in Butte. The Butte & Corbin Consolidated Copper Mining Co., with a capital stock of $700,000, will operate in the Corbin district. The directors of the company are J. B. Fitzpatrick, Martin Mulvahill, Lee Williams, and Lee Dever. The Butte & Red Eagle Copper Co. will operate in the Butte district. It is capitalized for $5,000,000, and the directors are J. D. Slemons, Fayette Harrington, James A. Canty, A. A. McMillan, Samuel Barker Jr., John W. Swain, and John D. Haines. The Eagle Mining & Smelting Co. has changed its name to the Copper Eagle Mining & Smelting Co. and has increased its capital stock from 150,000 shares of $1 each to 500,000 shares at 50c. each.

Officials of the Barnes-King Development Co. confirm the report that negotiations are pending for a consolidation of the Barnes-King, Kendall, and North Moccasin companies. If the consolidation is made the two other companies will be absorbed by the Barnes-King. The last has a contract for doing a lot of exploration work in the property of the two other companies, upon which it is now engaged. If the results are good the consolidation will be effected. There is a large mill on the Kendall, which would be an important acquisition itself, as it would do away with the necessity of building an addition to the Barnes-King mill. The properties of the three companies adjoin each other. Recently two large bodies of ore were opened in the North Moccasin. This property is owned principally by John A. Drake, of Chicago. The Kendall property changed hands some time ago for $500,000. The Kendall is valued at about $1,000,000. The Barnes-King Development Co. purchased the Barnes-King mines for $1,200,000.

The cross-cut being driven for the Davis-Daly Estates, south from the 1,800-ft. level of the Original mine, cut through the foot-wall of a vein, believed to be the Thomas, and the rush of water was so great that work had to be suspended. It is expected that work can be resumed in a few days. The vein was found where the engineers calculated the Thomas vein would be encountered, and it also is their estimate that the vein ought to be about 30 ft. wide, carrying good commercial ore. It is the intention of the company to continue the cross-cut a long way farther south, as there are four or five other veins lying in that direction within the Davis-Daly ground. Work at the other properties of the company is making good progress. The new 125-h.p. electric hoist has been installed at the Smokehouse shaft, and sinking has been resumed. The drifts on the 500-ft. level of the Smokehouse have not yet cut any large bodies of ore, as both the east and the west drift have found the vein badly broken. Work is being pushed at the Mt. Moriah, the Silver King, and Plymouth, and the Colorado. The shaft on the last named is nearly 1,000 ft. deep. When it reaches that depth a station will be cut and cross-cuts started north and south for the purpose of exploring the ground.

The Anaconda Co. has decided to sink all of its main shafts several hundred feet deeper at once, and the plan

Montana.

is to continue sinking while copper is high and open as much ground as possible in anticipation of a possible fall in the metal price; so that on a lower market expenditures may be confined to actual mining. All of the big shafts of the company will be sunk to a depth of 3,000 ft. The shaft of the High Ore mine is already 2,700 ft. deep and sinking is going on rapidly. The company is running levels at every 200 ft., and is now engaged in cross-cutting at the 2,600-ft. level of the High Ore. It is also developing the vein on the 2,400. In the Anaconda and Never Sweat mines the rich veins on the 2,400-ft. levels are being opened and proving big and strong all through the workings so far made.

The Butte-Montana Co. has ordered a new engine for the Alex Scott mine with a view to sinking the shaft to a depth of 1,500 ft. A station has been cut at 900 ft. and sinking has been resumed. The lowest level in the mine is at the 700, and some ore is being mined by the company on the 600. Good ore is coming from that part of the mine, but not in large quantities, as the vein there is small, though it contains some copper glance and other high-grade ore. The Alex Scott is well located and in the opinion of the management it will be only a question of depth to get big orebodies. The Butte-Montana is also mining some silver ore from the Little Annie mine, a property in the northern part of the Butte district.

Cripple Creek, Colorado.

Strike in the Hoosier.—Successful Leasing.—Rich Ore in the Modoc.—Gold Coin to be Unwatered.— Gold Dollar Production.— The Drainage Adit.—Blue Flag Cyanide Mill.

A strike is reported in the Hoosier mine, on Tenderfoot hill, at a depth of 670 ft. This property is owned by the Hoosier Mining Co., and is under lease to Marsh & Hodges. Samples taken across a width of 1½ ft. assay several ounces per ton. The lessees are also mining a low-grade orebody on the 400-ft. level, from which shipments are being made to the Wishbone cyanide mill.—— The Carey lease, on the Anchoria-Leland, situated on Gold hill, is making regular shipments of two to three cars per week. A vein of fair size is being mined west of the shaft on the 400-ft. level; it gives returns of $40 per ton.—— A small rich streak is being worked by lessees on the 700-ft. level of the Granite mine, east of the Gold Coin shaft. The lessees have recently made a shipment of 22 tons, which assayed 7 oz. per ton. The streak is oxidized.—— Ore is being shipped from the Fairview property, block 102 of the Stratton Estate, to the Golden Cycle mill at Colorado City. The first shipment ran $17 per ton, the ore being obtained from the 600-ft. level of the mine. Operations are being carried on through the Chicago & Cripple Creek adit, the workings being 2,000 ft. from the entrance. Raising is in progress on the vein, which averages 4 ft. wide, and better returns are expected from the next shipment.

Rich ore has recently been shipped from the Modoc mine, situated between the mill and Battle Mtn. A carload of screenings obtained from the 675-ft. level on company account ran around $150 per ton. Lessees are working the property from the surface to a depth of 500 ft., while below this company work is being carried on. ——It is stated that the Granite Gold Mining Co. intends to start the pumps at the Gold Coin shaft. The water is now within 33 ft. of the 9th level, and bailing will be commenced to uncover the big pump on the 1,000-ft. level. The unwatering of this shaft will help the draining of the Battle Mtn. properties.—— A circular letter has been issued to the stockholders of the Gold Dollar Consolidated Mining Co. giving an account of operations. The figures for April were not to hand, but for the three preceding months there were shipped 659 tons of ore, which netted to the company royalties amounting to $3,829. Ore has been opened up in four new places on the property by lessees. The first of these was made on the 6th level of the Mabel M., and has been developed for a little over 100 ft., and is from 4 to 16 ft. wide. Assays range from $20 to $60 per ton. The second strike was made in a raise from the 8th level on the east vein; it is about 2 ft. wide, and assays from $60 to $100. The two other strikes were made near the Union shaft and old Gold Dollar workings.

Wiring is in progress to connect the large motor situated at the portal of the deep drainage tunnel with the electric power at the El Paso mine. The recent bad weather has caused delay, but it is expected that the work will be completed within the next few days, so that the 12-drill compressor may be started to work as soon as the contract for driving the big bore has been let.—— The Union Leasing Co., operating the Proper claim of the Stratton Estate, on Gold hill, has found a promising vein 10 ft. north of the Proper shaft. The ore is 4 ft. wide, and was cut at a depth of 165 ft. Samples taken across this width run several hundred dollars per ton.—— Good ore has been found on the Mineral Rock claim, block 213 of the Stratton Estate, on Bull hill. Gus Johnson, who is working this ground under lease, struck the ore near the surface, and the vein as now exposed assays $100 across the entire width.

The cyanide mill of the Blue Flag Mining & Milling Co., on Bull hill, will commence operations during the next few days. Twenty-five tons of ore per day only will be treated at first until the plant is in full working order. The low-grade oxidized ores of the Blue Flag mine will be handled by the mill exclusively, there being several hundred tons already broken in the stopes.

Salt Lake, Utah.

More Copper at Bingham.—Last Chance Mill Started.—A Carpenters' Strike.—Shipments From Park City.

A shipment of 35 tons of copper ore from the New England Gold & Copper Co.'s mine at Bingham last week netted $40.33 per ton, the controls showing 8.1% copper, 0.32 oz. gold, 3 oz. silver, with an iron excess of 15%. This ore came from the Nast adit and was found in a hitherto unexplored portion of the property. It was also the first car of copper ore ever produced from the mine; the previous shipment being principally valuable for lead and silver. Henry M. Adkinson, the manager, is running the mill two shifts of 10 hours each and is making regular shipments of high-grade lead-silver ore. It is said there are four years' supply of mill-ore available without further development. The plant is treating about 60 tons daily.——The Last Chance mill of the Nevada Utah Mines & Smelters Corporation at Bingham is in operation again and is turning out about five tons of concentrate. The product contains about 10% lead and from 50 to 70 oz. silver. Superintendent Kirk makes the claim that a two years' supply of mill-ore has been developed in the mine.

A carpenters' strike at the new mill of the Boston Consolidated Mining Co., at Garfield, has had the effect of retarding the progress of construction work. The men wanted higher wages, but their demands were refused by the contractors. At the mine in Bingham, much activity is in evidence. Four steam-shovels are busily engaged in removing over-burden from the low-grade copper deposits, and a tramway is being built from the open-cut to the loading station, where the ore will be put on railroad cars for shipment to the Garfield mill. It will take 90 days to build the tramway.——The completion of the Markham Gulch mill in Bingham cañon is scheduled for about the 15th inst. While the plant is practically ready now, it will take two weeks more to finish the pipe-line through which it will be supplied with water. The mill is owned jointly by the Utah Apex and the Utah Development companies.

The ore shipments from Park City last week amounted to 2,457 tons, the contributing mines and respective amounts being: Daly-Judge, 925 tons; Silver King, 751; Daly-West, 601; Ontario, 180.——The development of the Ingot property in the Mercur district is now progressing steadily and with satisfactory results. The company has recently re-timbered and repaired the shaft. The plan to consolidate with some adjoining properties is still in abeyance.——The initial bars of bullion from the mill of the Jennie Gold Mining Co., at Gold Springs, Iron county, have been brought to Salt Lake, the lot weighing 14 lb., and being valued at about $1,500. The plant is handling about 40 tons of ore per day.——The Lower Mammoth Mining Co., operating in the Tintic mining district will soon declare its first dividend. Ore for shipment is being mined from the 1,700-ft. level.—— The grading of the new Eureka railroad has begun. This road will operate between the principal mines of the Tintic district and the smelter to be erected during the present year by the Tintic Smelting Company.

Toronto, Canada.

New Companies.—Larder Lake.—Shipments From Cobalt.—News of Developments.—Discoveries Near Sturgeon Falls.

Notwithstanding the depressed condition of the stock market, the formation of new companies shows no signs of falling off. Last week fifteen new mining companies, several of them being Larder Lake propositions, obtained provincial charters, the aggregate capitalization being $13,690,000. The conditions under which claims have been staked in the Larder Lake district are likely to result in endless confusion. Some 4,000 locations have been staked, not one of which has so far secured a patent, as this cannot be granted until the claims have been passed by the mining inspector and the required development work performed. A large proportion of them have been staked through deep snow and the stakes are likely to be swept away by spring freshets or otherwise removed. A large number of claims has been bought up by speculators and company promoters as the basis for concerns with big capitalizations, in which the public are now being asked to invest. Owing to the number of 'snowshoe' claims on the market, the prices at which they can be obtained are low, running from $40 to $100, which, under the circumstances, is probably more than some of them are worth.

Shipments of Cobalt ore for the week ending April 27 aggregated 93 tons from the following mines: Coniagas, 26 tons; Green-Meehan, 33; and O'Brien, 32 tons.—— Work on the big calcite vein on the Empress-Cobalt property, where a depth of 68 ft. has been reached, having been stopped by flooding from surface water, prospecting at the surface was begun last week and resulted in the discovery of a smaltite seam south of the main vein.——The Cobalt Lake Mining Co. has taken, from its No. 2 vein, 15 sacks of smaltite averaging 80% silver. Good samples have been secured from No. 5 vein at 46 ft. and small shipments will be made for testing purposes.——At the Trethewey, work has been begun on the new vein near the centre of the property and at some distance from the main workings. The two shafts will be connected when sufficient depth has been attained.—— The Progress Co., operating in the area south of the Temiskaming and Beaver mines, has sunk a shaft to a depth of 70 ft. and is commencing to drive at that level. ——The Duchess Mining Co., in the same neighborhood, is putting up camp buildings.

The Montreal Cobalt Co., which is sinking a shaft near Gillies station, has recovered the vein that was supposed to have pinched out.——D. M. Gilpin has returned from England where he was endeavoring to interest financiers in Cobalt properties. He is encouraged by the prospect, but reports that English investors want the endorsement of their brokers before buying. The firm of Gibbons & Co. has undertaken to send an expert to report on the Hazel Jule claim and incidentally on Cobalt conditions generally. Displays of Cobalt ore at the London immigration office are arousing some interest. John A. Church, mining engineer of New York, has gone to Larder Lake on an extended trip in the interests of New York capitalists, who intend spending a good deal of money in development work.

A few miles west of Sturgeon Falls, Ont., a vein of bluish quartz has been found 30 ft. wide, which has been traced over 80 acres. A shaft is being sunk and some samples showing pure gold have been obtained, and large pockets of copper pyrite have been cut. Farther to the west a large vein of bornite occurs, on which a shaft has been put down 20 ft. The ore is about 30% copper. A number of prospectors are looking for gold about 25 miles north of Sturgeon Falls. Some good finds are reported.

Denver, Colorado.

Mine Inspectors.—Contempt of Court.—Geological Work at Leadville.—The Next Senator.—Mining Opportunities.

T. J. Dalzell, Commissioner of Mines for Colorado, has announced the appointment of the Rev. J. R. Wood, P. T. Buckel, and N. J. McCarthy as mine inspectors.

The decision of the Supreme Court at Washington that there was no ground for appeal in the suits for contempt of court brought against T. M. Patterson will mark, it is to be hoped, the beginning of the end of this seemingly interminable litigation. It is refreshing to find that Senator Patterson has been defeated in every instance, and that the prostitution of the functions of the public press to serve as the means of forwarding partisan politics, and the gaining of unworthy ends, is not to be permitted. The abuse of the power of the press in this instance was particularly flagrant, for the attacks were chiefly launched at the Courts of the State, with the aim of undermining public confidence in them, and the arousing of public feeling against them. A newspaper that is a political asset deserves little respect; a newspaper that devotes its energies to undermining public institutions to gain private ends deserves to be suppressed. The next best thing is to fine the owner, and apparently that desirable result is about to be accomplished.

The preparation of the monograph upon the ore deposits of Leadville by the United States Geological Survey almost marked an epoch in the history of that institution. The keenness of observation and accuracy of inference in its preparation have been amply proved in the way in which the features uncovered by the later operations of mining have coincided with the predictions made in the monograph. So high is the regard in which this publication is held that if the miner discovers a lack of coincidence in some minor point, his first thought is that it is the fault of the rocks, rather than of the geologist. The report as a whole stands as one of the monuments of American geological research into economic problems. A short while ago, under the direction of the author of the original report, S. F. Emmons, a revision of it was made to incorporate such features as the greater exposures in the vastly increased workings had made more clear. One point not entirely cleared up at that time is the course of the Ball Mtn. fault through the region about South Evans gulch, and some companies have spent considerable sums in attempting to follow up ore-shoots that proved to be cut off. During the present summer J. D. Irving will make a careful examination of this area in order to map the fault accurately. No better example of the economic application of pure science could be desired. A brief period of study by a technical man with adequate training for the purpose will obviate the necessity for the expenditure of large sums of money, and equally valuable time.

Political rumors as to the probable successor of Senator Teller are already beginning to circulate. It is said that the party leaders in Denver are in favor of F. E. Brooks, while the Howbert wing of the party supports C. C. Hamlin. In either case Colorado Springs seems to be slated to furnish the next United States Senator for Colorado. Jesse F. McDonald, of Leadville, and A. E. Bent, the present State treasurer, are the candidates mentioned for the governorship.

Colorado can scarcely regard the present boom in Nevada with simple sisterly pride and affection. Many mine owners who have profited from investments in Colorado properties are now investing their surplus in Nevada. "The distant hills," they say, "are always green," and there seems to be an allurement which dis-

tance casts about a mining district that makes it seem more attractive than one nearer home. It is not to be forgotten that though the chances for gain in the sudden development of new districts are greater, the chances for loss are correspondingly increased. The most substantial fortunes have been taken out of mining camps after their booms have long subsided. On the man who puts his money into a boom camp, just as he might perhaps lay it on the turn of the roulette wheel, for the fun of the thing, and not caring much whether he may win or lose, there can be no comment other than that it is his privilege. But the Colorado man looking for substantial mining investments can find enough of them at home.

Pioche, Nevada.

A Lively Camp.—Building of the Railroad.—Lack of Lumber.—Lawson and His Antics.

Pioche is beginning to feel the vivifying influence of the incoming railroad. The usual advance guard that precedes a boom is here and the numbers are increasing daily. Every available bed in the town is occupied each night, and one or two new tents go up daily.

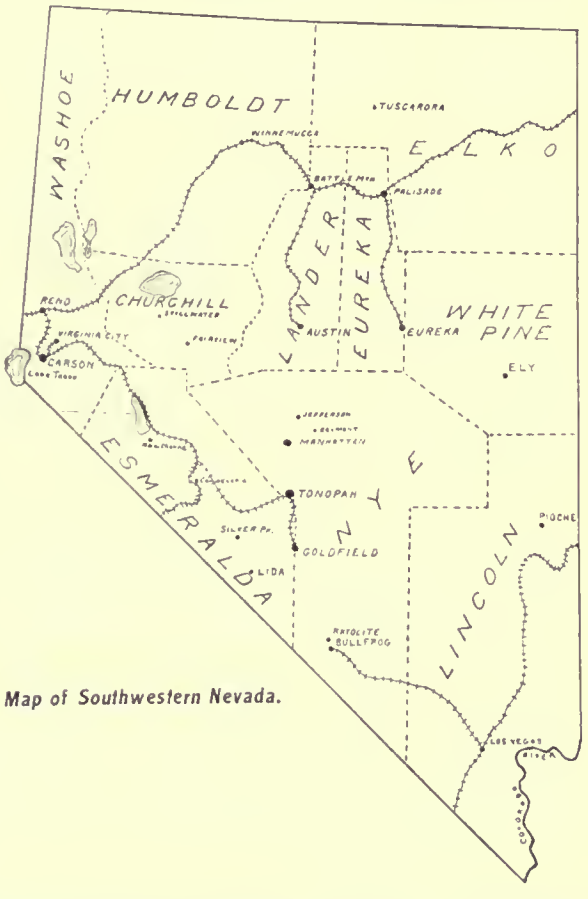
Mendenhall & Deal, the contractors for the new line, are crowding the work just as fast as they can with the force obtainable. Report comes in that men are shipped to Caliente by every train, but that many who have had their fare paid on the railroad, desert, either without reporting at all at the grading camp, or quit after doing a day or two of work. In spite of such annoyances, which are not without precedent in these days of prosperity, the grade is already finished three miles this side of Caliente, ties have been distributed for some distance and laying of steel is to begin at once. Unless some unforeseen hindrance occurs, the cars may be expected here some time in July. Word comes from Caliente that the material for the new Pioche depot has begun to arrive, and that it is the purpose of the company to erect an imposing structure here. Perhaps the most important railroad news is an item from Los Angeles, given me last evening by a man in a position to get inside information. He tells me that the line is to be extended without any stop whatever to a distance of 46 miles from Caliente. As the Ida May property, which has recently been secured by W. A. Clark, Jr., is just 46 miles from Caliente it seems reasonable to suppose that the railroad will go without delay to that property.

The Bristol, just across the hill from the Ida May, has already begun shipping by wagon to Caliente, whence the ore goes by railroad to Salt Lake. This seems to confirm a persistent rumor of a strike of high-grade copper ore recently made in that old property. It seems rather extravagant to pay $14 per ton for wagon freight on ore that in a few weeks could be put onto the cars for not to exceed three dollars, but probably the management feel that they have a reason which justifies their action.

The crying need of Pioche is lumber, of which not a foot is for sale in the town. No one had the nerve to put in a stock last year when a contract could have been made to freight it in from the railroad at $8 per thousand. Now the price is $15 and teams can only be had to bring in a few hundred feet occasionally. The amount of freight of all kinds awaiting transportation from the railroad exceeds the capacity of the wagon outfits on the road. Last week I had to pay $20 per ton to get freight in from Caliente as against $8, the prevailing rate a year ago.

A great deal of prospecting is being done in the hills in every direction and new strikes are daily reported. A number of the old properties have a tonnage already in sight running up into the hundreds of thousands of tons in the aggregate, which will be waiting for the cars when they arrive. Of this I hope to speak more in detail in subsequent letters.

Two months ago today the papers of the East were ablaze with announcements headed 'Coppers, Nevada-Utah' and signed by Thomas W. Lawson. For weeks the resources of the 'lambs' waxed and waned and a large portion of that susceptible community lost much sleep listening for "the reports of my experts," who were represented as being diligently engaged in examining the Bingham and Pioche properties of the Nevada-Utah. Each day they were fed some new variety of pabulum, but the dish was always labeled 'Coppers, Nevada-Utah.'



Map of Southwestern Nevada.

The announcement of March 5 stated "I now have the reports" and gave the assurance that the following day the announcement would contain his "conclusion." The following day an expectant public was told that "after going over the experts' reports of the different Nevada-Utah properties I must postpone my decision, etc." March 8 the announcement said "This space is reserved for the report of the mining experts engaged by me to examine the different properties owned by the Nevada-Utah Company." Whether he is still announcing and the hearts of the lambs still palpitating I do not know. In view of all this frenzied finance, it is interesting to know that at neither Bingham, Pioche, nor Jack Rabbit does the Nevada-Utah possess a single copper mine, although it does possess at each place some exceedingly valuable silver-lead properties. Also in this connection I may quote a statement made to me a day or two ago by Mr. Latfan, general manager of the Pioche and Jack Rabbit properties: "No person on behalf of Mr. Lawson has ever visited the property of this company under my charge to make an examination, or for any other purpose whatsoever." Mr. Freundenthal, who for two years prior to April was superintendent of the property, emphatically confirmed Mr. Latfan's statement.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A CAM SHAFT is generally long enough for two batteries with the overhang for one pulley. Driving single batteries materially increases the expense of belts and pulleys.

FIFTY YEARS AGO the copper-blast furnace consisted of a small shaft, lined with firebrick or stone, and having at its lower extremity a crucible for the collection and separation of matte and slag.

ROASTING REACTIONS are confined mainly to the surface of the layer of pulverized ore which lies upon the hearth, and the deeper sulphide particles experience but little oxidation as long as they are buried, unless left for a long time.

IN the average mill the question of slime treatment generally offers room for improvement. In considering the question there are two general ideas to be considered —the prevention of slime as far as possible and the treatment of such as are unavoidably made.

THE dynamite which has been under water at the bottom of the 700-ft. well, should not explode on being exposed to the air. In fact, it will probably be found difficult to explode it, even with a strong cap, and if it can be exploded at all, its force will be found greatly diminished.

BY PYRITE SMELTING is meant the smelting of a pyritous ore mainly by the heat arising from the combustion of its own constituents. Complete pyrite smelting has not yet become continuously feasible in practice, and in all pyrite furnaces a small amount of carbonaceous fuel is added to the charge.

THE difference in the explosion of compounds and powder, is that in the former the whole charge explodes simultaneously by concussion, while with powder the fuse sets fire to and explodes the grains nearest it, these communicate the fire to those touching them, and so on, until the whole charge is fired.

THERMOCHEMISTRY is that branch of chemistry which deals with the amounts of heat evolved or involved in chemical reactions. It is the most important side of chemical science for the metallurgist, because it concerns the whole subject of the utilization of fuel, and the reduction of metals from combination.

STATISTICS indicate a big increase in the consumption of sheet mica during the past year, in the United States. The imported mica comes from Canada and India, this country taking about one-half of the output of the Canadian mines. Ground mica, of Canadian origin, is not imported on account of the tariff.

IN the production of steel, varying proportions of ferromanganese or spiegeleisen are used, depending on the character of the product desired and the process used, and to supply this need the bulk of the manganese ore imported as well as the domestic ores are smelted to produce 'ferro' or 'spiegel,' and liberal quantities of these metals are also imported.

IN milling concentrating ore, the cleaner the concentrate, the greater is the loss in the tailing, and consequently the less is the saving. The question is, whether the value of the high-grade concentrate more than offsets the increased loss in the tailing. Local conditions, such as freight rates, smelting charges, and quality of the ore, generally decide this point.

DOUBLE DISCHARGE MORTARS have been found unsatisfactory in many stamp-mills, because a mortar of this kind requires more water per ton of ore stamped; it gives less time for battery-amalgamation; the splash acts less violently upon the screens, which are more likely to clog; and the back screen is generally awkwardly situated for changing or inspection, and is often neglected.

THE production of manganese ores in the United States is not important in either quantity or value, for most of the manganese ores used here have been imported from foreign countries. The quantity of manganiferous ores produced, however, is much in excess of that of manganese ores, the distinction between the two being practically based upon the manganese ores yielding 40% or more of metallic manganese.

IN reply to the question sent us from Columbia, Cal., it is difficult to advise about breaking ground with the meagre details given. If the rock is a hard limestone, we would suggest using quicker powder—certainly not slower—and a wide centre cut angle, and then long back and breast holes, and lifters. We should consider black powder as entirely unsuited to the work. Try deeper holes, faster powder, and heavier loads.

THE electric motor adapts itself to various conditions, and frequently is used to supply the motive power to a device which competes directly with a similar electrical device. For example, the chief competitor of the compressed-air rock-drill is the electric drill, and one of the later and interesting developments of compressed-air drills has been the addition of a small electric motor driving a little local compressor for supplying the operating power to the drill.

THE source of commercial muscovite is generally pegmatite dikes. These are vein-like masses largely composed of the granitic minerals, quartz, feldspar, and mica, and are common in most areas of crystalline rocks, whether granites, gneisses, or metamorphosed sedimentary formations. The dikes intrude the country rock, following whatever planes of foliation may be present, or cutting across these and often passing into irregular bodies of considerable size.

THE asphaltenes are probably unsaturated hydrocarbons, or derivatives of them, in highly condensed form, possessing a high molecular weight, but concerning their structure, comparatively nothing is known. They contain the major part of the sulphur extant in asphalt, and are characterized usually by the presence of remarkable quantities of it. The higher the sulphur-content the harder the asphalt. Normal asphalts leave, after heating, about 15% coke residue, a fact which enables us to distinguish them by this characteristic alone, from other solid bitumens.

THE demand for the mineral monazite, which contains the oxides used in the manufacture of mantles for the Welsbach and other incandescent gaslights, is constantly increasing, and many inquiries are made regarding the source of supply of this mineral, not only for domestic but also for foreign consumption. Although monazite has been found sparingly at many localities throughout the United States, the Carolinas are still the only States that are producing this mineral commercially. The results of the investigation of the Geological Survey, at Portland, have shown the presence of some monazite and more zircon in many of the sands of the Pacific slope, especially in those from Oregon and Idaho.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Cyanide Practice at the Waihi.

The Editor:

Sir—In your issue of December 15, 1906, under the heading 'Progress in Cyanidation,' the statement is made that "at the Waihi, treating 25,000 tons per month, it requires seven men continuously to clean the boxes, using zinc shaving."

This statement is apt to convey a wrong impression, the position being that these men not only clean the boxes weekly at three separate plants cyaniding a total of 27,000 tons per month, but also do all work connected with the acid treatment and smelting (weekly) of the zinc-gold slime, amounting to about five tons dry weight per month, and producing over 100,000 ounces of bullion.

E. G. BANKS.

Waihi, New Zealand, March 15.

Ore Deposition.

The Editor:

Sir—The metals gold, silver, copper, platinum, and more rarely iron, are found in a metallic state in nature and are commonly called 'native.' The word 'native' as applied to these metals carries with it the implication that they are original depositions.

The usual explanation of their being in a metallic condition, is that they have been derived from the baser ores by action of surface waters. All surface waters carry air, carbonic acid, and salt in solution; and through the oxidizing action of the dissolved air, the sulphide ores are changed to sulphates, oxides, and chlorides. The soluble salts being carried down along the veins encounter unaltered sulphides and the reducing action of the sulphides on the sulphates results in depositing the metals in forms intermediate between the two.

This seems to be a satisfactory explanation as applied to sulphide ores of copper, such as occur in Montana and Arizona. The zone of secondary enrichment is usually present at from 300 to 800 ft. in depth, and within this zone the mines are in bonanza, while below that zone usually they get into poor ore. The upper portions of the Butte veins were free of copper and were milled for gold and silver. The Anaconda company started to build an amalgamating plant before they discovered that they had a copper mine.

There is usually enough salt in the surface water to precipitate the silver as chloride; and in this form it is found occasionally in large amounts as horn silver, some of the mines of Leadville, Aspen, and Tombstone being noted for such deposits. In desert regions, almost without exception, that silver occurs in the oxidized portion of the veins as chloride. So much is this the case that it gave rise to the term 'chloriding,' as meaning prospecting for chloride ores of silver.

Native silver is sometimes found in the zone of secondary enrichment, but that is rather unusual; and its presence in large quantity suggests another cause of deposition. Where the climatic conditions are favorable to the growth of a large amount of vegetation on the outcrop of the vein or in the drainage passing over the outcrop, then by the decay of such vegetation, organic matter will be added to surface waters. This organic matter will act as a reducing agent and precipitate silver and copper from their sulphate solutions. The growth of vegetation requires rainfall and is in direct proportion to it. The increase of rainfall would dilute the surface waters and decrease the percentage of salt derived from the decomposition of the rocks. Therefore, the silver should occur as chloride in the oxidized ore of veins in desert countries and as metallic silver in countries where rainfall and vegetation are abundant. This, I believe, is the case; at least, chloride ores predominate in desert countries. When the ores contain arsenic the silver frequently occurs as ruby silver as a result of secondary enrichment and it should be in that condition at Cobalt if due to secondary enrichment.

The ores of Cobalt, in Ontario, have been the subject of much investigation and speculation as regards their genesis and I have proposed a theory to account for the presence of the metallic silver below the zone of secondary enrichment. Glaciation of the surface has gone to such great depth and has been so recent that there is no zone of secondary enrichment of any consequence.

Throughout these northern regions unaltered sulphides occur at, or near, the surface, and any explanation of the occurrence of native silver should not pre-suppose a zone of secondary enrichment.

At the Toronto meeting of the Canadian Mining Institute, Prof. Van Hise read a paper on the geology of the Cobalt district. In the discussion of his paper, I offered the suggestion that the metallic silver was deposited contemporaneously with the other minerals by the action of hydrocarbon gases asssociated with the ascending hot solutions. Prof. Van Hise and others took the ground that the metallic silver came from above and was due to secondary enrichment. I suggested that the presence of graphitic stains on the walls of the veins, on slickenside surfaces, as well as the graphite associated with the ore, indicated that hydrocarbons had been present during deposition. If present, they would act as powerful reducing agents and precipitate metallic silver. This method of deposition would avoid the necessity for pre-supposing a zone of secondary enrichment, which may have existed, but has since been eroded. The suggestion was not received with thunderous applause, but it brought out the fact that graphitic stains and carbonaceous material do occur with the ore. It was further stated that in the Silver Islet mine, near Port Arthur, the same deposits of graphite occur associated with metallic silver, and that hydro-carbon gases were encountered in the mine workings in sufficient quantity to burn under rock pressure and to cause trouble with the ventilation. The Silver Islet mine is directly north of the copper mines of Michigan and no great distance from them.

The presence of hydro-carbon gases in mineral veins is therefore established, and the record of their having been associated with the mineralizing solutions is attested by the graphitic deposits referred to. However, I had the honor of being a minority of one in connection with this suggestion, and since that time I have been looking for corroborative evidence. In a communication published in *The Engineering & Mining Journal* of March 30, I set forth the effect that such reduction during deposition would have, and suggested that the same principle might account for the deposition of the metallic copper in the Lake Superior region. Since that time I have read in 'The Geology of South Africa,' by Hatch and Corstorphine, that "In some rich conglomerate reefs, carbonaceous matter is plentifully present; possibly this substance may have played a part in the precipitation of the gold."

It seems more probable that the carbonaceous matter is the result of deposition from hydrocarbon gases, and that the gold was also precipitated by the gases associated with the solutions. With a precipitating agent associated with ascending hot solutions, deposition would

take place in proportion to the relief of pressure and reduction of temperature, and this would be greater near the surface. It is the sad experience of miners that ores do not get richer with depth. Secondary enrichment may make it appear that they do so for a short distance, but below the zone of secondary enrichment the decline is persistent in both size and grade. Who has not listened to the optimistic prospector telling how his vein is like a wedge with the big end down? And who has not had the sad experience of parting with his money, because the prospector did not know and could not understand (even as you and I)?

The advocates of the different theories of ore deposition seem to be divided into classes, which, for brevity, may be called magmatic segregationists, lateral secretionists, and hot-water men. The third group is divided into two groups, one of which believes that the water derives its heat and minerals from intrusive masses near the surface, the water being of surface origin. The second group, of which I count myself a member, contend that the water is of magmatic origin and is an addition to surface waters. These waters, in addition to the dissolved minerals, contain various gases in the same manner as the emanations from volcanic vents.

It is a well established fact that various hydrocarbons are discharged from volcanic vents, and Mr. Eugene Coste has written a most excellent paper on the volcanic origin of petroleum and natural gases. On this hypothesis it is conceivable that mineralizing solutions could contain them, and their actions on solutions containing gold, silver, and copper would result in precipitating the metals in a metallic state. The presence of hydrocarbons would be necessary for the precipitation of native metals below the zone of secondary enrichment, and in cases where these native metals do not occur, it would appear that hydrocarbons were absent during deposition.

In the case of Lake Superior copper ores, as all the copper is present in the form of metallic copper, this fact precludes the possibility of its being derived from pre-existing sulphides. As it is in many cases associated with conglomerate beds of sedimentary origin, it plainly was not deposited by magmatic segregation. If the graphitic material associated with vein-matter were the precipitating agent, then the greatest amount of metal should be in direct contact with it. This is not the case, and it therefore appears that the graphitic material is merely incidental to the presence of the hydrocarbons.

Instances have been known and recorded where lavas have yielded hydrocarbons from amygdules, and the flowing asphaltum spring of Trinidad is hot. Under such conditions it seems reasonable to suppose that iron might be reduced to the metallic state and remain as grains in suspension in the viscous mass. This would explain such occurrences as are known in Greenland and also the ferro-nickel beach sands of Martinique.

In 'The Geology of South Africa,' above quoted, the authors, referring to the origin of diamonds, say: "From the state of strain in which the diamonds are sometimes found—a condition which occasionally results in their destruction—and from the presence of cavities containing gas under enormous pressure, it is certain that they were formed at great depth." Here we have again evidence of the presence of hydrocarbons in the diamonds themselves, pointing to their being crystals of pure carbon derived from hydrocarbon gases under enormous pressure and temperature dissolved in the magma of 'blue ground.'

The different volcanic necks that contain the diamonds yield varying amounts per load, and some necks, which have all the characteristic appearance of productive mines, are barren of diamonds. This seems to me to indicate that the hydrocarbon gases necessary to diamond formation were absent in some cases.

If the magmatic waters contain hydrocarbons and cause the deposition of native metals in veins and diamonds under other conditions, is it not possible that both gold and diamonds might be deposited in the same vein?

In this connection I wish to refer to the reported occurrence of placer gold and diamonds in the same gravel beds at various points, especially in Brazil.

I think this question of reduction during deposition is deserving of more than passing attention on the part of men interested in ore deposition.

HIRAM HIXON.

Victoria Mines, Ontario, April 11.

Undesirable Citizens.

The Editor:

Sir—The letter of the President, and your comment thereon, in your issue of April 27, indicate that you possess some knowledge of the acts and utterances of Moyer and Haywood not known to the general public, and that you are either ignorant of, or ignore, facts that are generally known to others. If such is the case it seems but right that the public should have the benefit of what you know, and I shall mention some of the things that the President and yourself don't seem to know. Both of you intimate that these men are guilty of other crimes besides that for which they are now held; but if so, why have they never even been tried for them? Their bitterest enemies have for years had complete control of the States of Colorado and Idaho, and the backing of the National administration; and have made use of the governors, legislatures, and courts, and of the soldiers, sheriffs, and Pinkertons without daring to even put them on trial.

They abused them, beat them, threw them into jail, and tried to frighten them out of the country, and failing to do that, had the soldiers take them out; their whole treatment being a fine example of the "square deal" for which the President calls for so vociferously. Utterly baffled in all their attempts to drive these men out of Colorado, or to hold them in prison there, their enemies next made use of the Steunenberg murder as a pretext for kidnapping them, carrying them to Idaho and imprisoning them; the whole proceeding being a most shameless travesty of law and justice.

Their treatment in Idaho would have been a disgrace to Russia, until their comrades took up the matter and the force of public opinion made it more decent, but it brought no word of disapproval from the apostle of the "square deal," though he went out of his way in his 'muck rake' speech, to refer to them as labor leaders "implicated in murder." It was not until these men had been months in jail and had tried in vain to get from the courts the justice they were entitled to, that their comrades asked the President to help them get it, and surely they are not to blame for hoping that the Strenuous One who was willing to use the whole military force of the nation to put a few Japs into the white schools of San Francisco, would at least notice their petition. These men have been kept in jail 14 months without trial; the Governor of Idaho says, "they are guilty and will never leave the State alive"; the judges and other State officials are their avowed enemies; the United States judges wrap themselves in their robes and disclaim jurisdiction, and the President again gratuitously refers to them as undesirable citizens; yet he is shocked at the moral obliquity of their comrades in demanding an explanation and a fair trial, and tries to turn public sentiment against the unions, by representing them as defenders of criminals.

who are entitled to no consideration whatever even if not convicted of the murder of Steunenberg. Let me add that I am not a member of the W. F. L. or any other organization or union, and that my only motive in writing this is love for a "square deal" that is "square."

J. A. LA GRAVE.

Greenwood, Cal., May 1, 1907.

[We are not possessed of any exclusive information on the subject mentioned, nor apparently is our correspondent, although he makes a number of assertions that are without basis of fact.

If the legal advisors of the men mentioned had been willing to bring them to trial, the case would have been settled long ago in the ordinary course of events. The removal of Moyer and Haywood from Colorado to Idaho has been passed upon by the Supreme Court of the United States and we happen to be among those who accept its decisions as authoritative and just—within the limits of human judgment. If the method of arrest was unusual, so also were the circumstances, as is well known to the mining communities of the West. It is a mistake to refer to Russia; in that country the methods of industrial and political agitation adopted by the Western Federation of Miners would have been abruptly terminated long ago. Fortunately their leaders are in the United States and they will receive fair trial. The majority of thoughtful people deplore the vendetta that disgraced Colorado a few years ago and only ask that all law-breakers shall be punished. At that time we ventured to condemn the mine operators for their high-handed acts, and for taking steps that tended toward the break-down of popular government in Colorado.

The law is greater than either the mine workers or the mine operators, and the support of it is essential to what is termed civilization. We approved the letter of the President and we admired the manliness of his utterance because he said what most men are afraid to say, namely, that Harriman and Haywood are alike 'undesirable citizens.' For ourselves we feel that most of our readers are fairly well aware of the labor unrest—if not worse—that we owe to Moyer, Haywood, and Debs, while the mining community as a whole does not realize sufficiently that Harriman is equally as undesirable and as much more to blame as his association with educated and thoughtful men has given him standards of morality that he has flouted. The fact that he has millions makes his wrongdoing the bigger and his responsibility the greater. This would be more fully recognized if all of us were not a bit obsessed by the vision of stupendous wealth; a man steals ten dollars and he is called a thief; another transfers a million to his pocket and he is a financier; a third juggles with the stock of a big railroad and enriches himself by ten or twenty millions, and he is labeled a great man. Nevertheless, each act is dominated by the same motive and the larger scale of the performance ought to make it so much more damnable, in that it affects the interests of an increasing number of people and is performed by men of greater intelligence. It is well to ventilate these matters and that is why we publish our correspondent's letter, giving him a square deal to the extent of telling him that we disagree wholly with his perverted sentiment.

Obviously the arrogant labor leaders are astounded at the President's daring; they never expected so clever a politician to speak so frankly. They have been holding mass meetings and trying to influence public sentiment in advance of the trial, attempting, in fact, to make a fair trial impossible—the very thing charged to the President.

They are enraged because their tyranny over the laboring men in the West is challenged. They have thriven on the weakness of corrupt politicians and they are startled by the retort of a fearless statesman; he called their bluff. And if further evidence is needed of the sort of thing that Moyer, Haywood, and Debs stand for, it can be found in the *Appeal to Reason*, a wretched sheet which, like Hearst's newspapers and a good many others, disgraces journalism and exhibits the vulgar license to which the liberty of the press has descended. In the issue of April 20 we find a long article by Debs vilifying the President, a mere rigmarole of perfervid rot, illustrated by disgusting caricatures and topped with the call 'Down With the Despot!' This won't do in America, and the sooner organized labor separates itself from such advocates, the better for it. The public is getting weary of the preaching of violence and the incitement to disorder by those who speak for the labor unions, just as it is impatient over the corrupting tyranny of predatory financiers and the cheeky effrontery of men who, while trustees for investors, play the market like common gamblers.

The President spoke the truth in a fearless way, and we honor him for it.—Editor.]

Slime-Filtering.

The Editor:

Sir — Seeing the necessity for a continuous filter in connection with the slime treatment of silver ores, and not finding any reference in your valuable journal, I wish to call your attention, and that of some inventor, with means to perfect the idea, to the filtering by centrifugal force, as in the sugar mills, with the difference of raising and discharging the cake over the rim by fixed scrapers, the cake to fall into a second centrifugal machine below the first, where it is washed and filtered with weak solution to be finally discharged with water.

Although convinced that the ever alert inventor has this idea near practical perfection, it would be perhaps a benefit to the mining industry to have it worked out without patent, and for this reason my insinuation in case nobody should have taken one on this method.

Please use this to the best of your judgment without any name.

OLD SUBSCRIBER.

Mazatlan, Mexico, April 12.

Salton Sea.

The Editor:

Sir—I notice in a recent issue that one of your correspondents ridicules the idea that the filling of the Salton Sink has influenced the climate of Nevada, and goes to considerable trouble to show that the evaporation from such a small body of water would not produce much rainfall. All of this is perfectly obvious. A glance at any map will show the relative sizes of the Salton Sink and of the desert. Modern investigation of rainfall has shown that rain is produced by areas of high barometer followed by areas of low barometer and that these conditions chase each other across the continent along certain paths. I think that with our present limited knowledge of the subject it would be impossible to say just what influence the Salton Sink may have on the meteorological conditions and hence on the rainfall. It does not, however, seem altogether improbable that the slight change in temperature and humidity on the *east side* of the Sierras brought about by Salton Sea may have materially altered the path of the rain-storms. It takes less force to alter the path of a current than it does to start or stop one.

GEO. J. BANCROFT.

Denver, April 18.

Mining at Bingham, Utah.

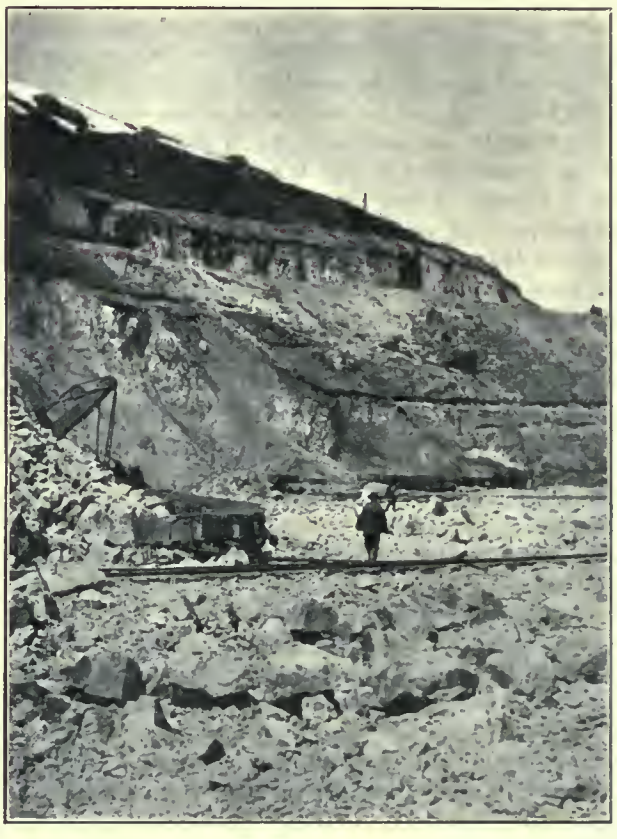
Written for the MINING AND SCIENTIFIC PRESS
By JAMES W. ABBOTT.

The stranger visiting this camp for the first time is, I think, impressed especially by the enormous areas of mineralized ground, mostly of low tenor, and the ingenuity of man in elaborating methods for realizing profit therefrom. Until quite recently the greater part of the material now designated as ore was worthless country rock, or sulphide mineral too lean to be utilized.

Bingham is one of the oldest mining camps in Utah, but in the earlier days its products were practically limited to gold, silver, and lead.

In all the history of mining, an industry ever fascinating perhaps for its surprises, no more astounding romance can be found than the transformation of the Highland Boy in Bingham cañon. Regarded and equipped as a gold producer, and fairly profitable for a time as such, after awhile the returns dwindled, then profits ceased, and the surplus capital evaporated until utter failure threatened its promotor, Samuel Newhouse, then on the threshold of his mining career. But just when the crisis was imminent, material that had been going over the dump as waste, was discovered to contain an unsuspected mineral, and Mr. Newhouse found himself at the head of one of the great copper enterprises of the day.

Looking Up Bingham Canyon. Highland Boy Buildings in View.



Deep Cut Into Overburden. Keystone Driller Sinking, Steam-Shovel Loading, and Train Removing the Waste.

Fortune, which has been so conspicuous in its attentions to Mr. Newhouse, had other equally startling surprises in reserve for him, in the very field of his original great success. On the opposite side of Bingham cañon he gradually acquired control of large holdings not included in the Highland Boy combination. In these claims diligent prospecting at length disclosed enormous lenses of copper-bearing sulphides, formed by replacement in limestone. And even this was by no means the limit. Further investigation revealed the fact that hundreds of acres of the old igneous intrusive monzonite porphyry, through the agency of a later eruptive, perhaps the same one that caused the replacement in the limestone, had been impregnated with copper-bearing solutions, which left in it a sufficient amount of this mineral in such condition and distributed with such astounding uniformity that the whole mass to great depths was turned into ore.

It is interesting to compare the large orebodies of Bingham and Ely, each of which is to be numbered among the world's greatest copper districts. At Bingham, as far as disclosed, it appears to be monzonite that has become ore through the influence of a later eruptive, while at Ely the great deposits in the Ruth and Copper Flat mines have been found to be later eruptives mineralized as the result of processes in which monzonite played an important part. By this statement I do not mean that anyone has suggested that the monzonite at Bingham has derived its copper principally from the late eruptives, or that the converse holds at Ely. In the complicated processes acting through many geologic periods each of those igneous rocks has played its part. Now it appears that at Bingham nature has prepared the monzonite for man's profitable use, while at Ely it chose the rhyolite for that beneficent function. The student of economic geology will hope that as development proceeds in each camp some new facts will be disclosed calculated to aid us in learning the complicated scheme of ore genesis from the first appearance in geologic time of any valuable element to its final concentration for man's use.

To reach Bingham one goes on the main line of the Denver & Rio Grande railroad, 11 miles east to Bingham Junction, then southwest, on a branch 14 miles, making 25 miles in all; the time consumed each way is one hour and ten minutes, with double daily train service. About five miles below Bingham is the junction of this branch with the new double-track line to Garfield, where the American Smelting & Refining Co. has already in operation a smelter of 2,000 tons daily capacity; the Utah Copper Co. (known as the Guggenheim property), is

about completing a concentrator to reduce (in the ratio of 20 to 1), over 4,000 tons daily of the Bingham monzonite ore, and where within six months the Boston Consolidated (known as the Newhouse property), expects to put into commission its concentrator of about the same capacity for a kindred purpose. It is a suggestive fact that neither of the three corporations just mentioned seems to feel half the concern about its own stupendous problems that it does about the ability of the double-track standard-gauge steam railroad, 21 miles long, to handle, as its exclusive traffic, the tonnage that Bingham will send to Garfield.

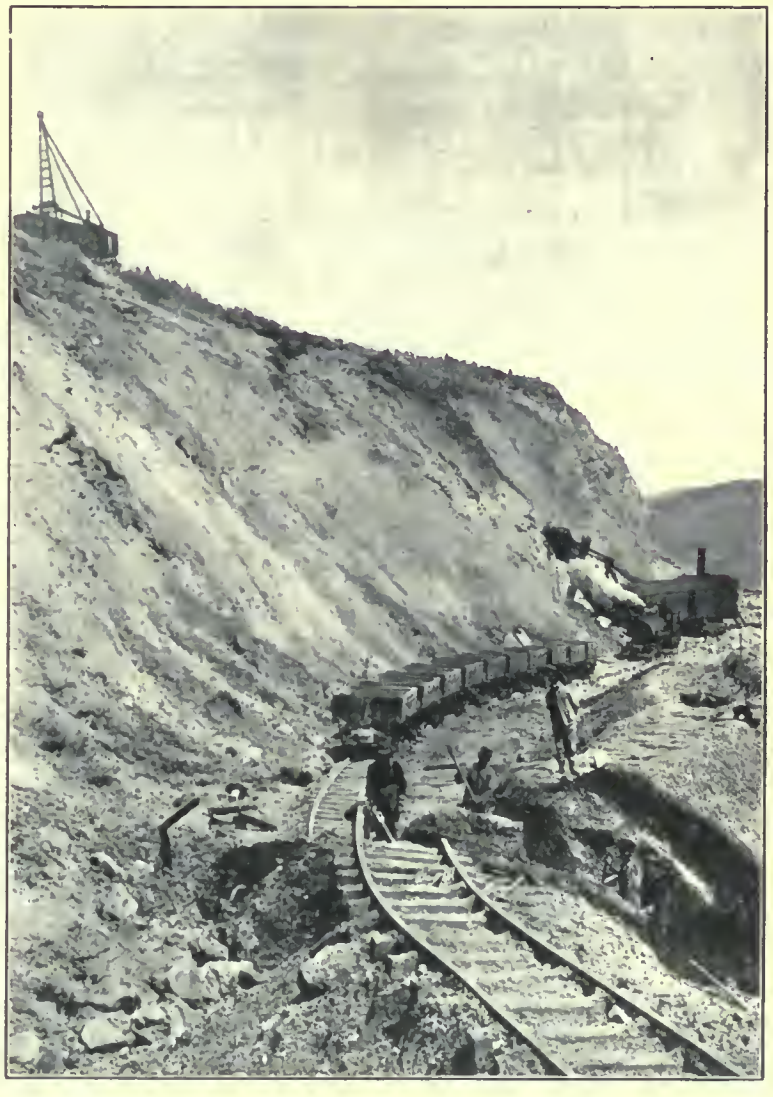
Two miles below Bingham, on the branch line, is the smelter of the Yampa Consolidated, which has been running successfully for a number of years. Half-way from this smelter to Bingham is a concentrator where the Utah Copper Co., treating 1,000 tons per diem of the monzonite ore, has demonstrated to its own satisfaction that it can produce copper therefrom at a cost of 10 cents per pound. I am advised by a conservative mining engineer, in a position to know the facts, that the Utah Copper has opened up within its ground 36,000,000 tons of this ore of an average tenor better than two per cent.

Arrived at the Bingham station the stranger finds about him a scene of impressive mining activity. Continuing up Bingham cañon, through which the railroad has come on a steep grade, runs the wagon-road to the offices of the Boston Consolidated and Utah Consolidated (the Highland Boy), each about two miles from the depot, while to the left is another branch of the cañon leading to Upper Bingham. The grade of the road up the cañon is very steep, seldom easing up to less than 12%, and reaching 30%, in places. The little opening occupied by the depot, and a few business houses, soon narrows to a width just sufficient for a narrow road, above which the houses stand on shelves dug into the hillside. On both sides the hill rises rapidly, the slope in places reaching 40%. Running all over the hillsides, to a height of 2,000 ft. or more above the town, may be seen the Copper Belt railroad, a standard-gauge feeder of the Denver & Rio Grande. Connecting with it is the narrow-gauge line of the Boston Consolidated, with its nine dinky engines frisking about like a lot of wild colts. In every direction, from adits, shaft-houses, and head-frames to smelters, concentrators, and railroad-bins are seen wire-tramways, with buckets that seem to flit about like a flock of birds. No wonder Salt Lake City feels jubilant with golden streams flowing into it from mints like Bingham, Tintic, Park City, and Ely.

Besides the Boston Consolidated, Utah Copper, Utah Consolidated, there are now operating at Bingham the Ohio Copper Co. (a Heinze property), Utah Apex, United States (property of the United States Smelting R. & M. Co.), Bingham Mary (a Bamberger property), Phœnix, Bingham Consolidated & Bingham, and the New Haven Copper & Gold Mining Company.

From its sulphide property the Boston Consolidated is sending daily to Garfield 750 tons of ore, which is loaded from bins at the mouth of the lower adit into cars for the smelter. From this deposit, which averages better than 3%, and is in places over 100 ft. wide, stoping is being carried on at three levels, the ore being dropped to the first, and there trammed out to the bins. On the same level as the bins are the sawmill and the lumber-yard. The cars that come for ore bring up the supplies and lumber, and the only hoist that will be required on the property for a number of years is a small one used to handle lumber and supplies from this yard to the upper levels.

About a hundred feet above the upper levels, upon a large yard built of waste from the overburden, are the engine-house, car and machine-shops of the dinky railroad. While the great concentrator is being made ready, this railroad is removing the overburden from the monzonite ore. Four 5-yard bucket steam-shovels are used, after Keystone drillers have determined the depth of the overburden, at points carefully located on the ground and on the map. This overburden, principally quartzite, is shaken up with giant, loaded by the steam-shovels onto the cars, and hauled away by the dinkies. The sulphide ore pays the bills.



Preparing to Lower the Track 10 Ft. and to Advance the Steam-Shovel.

The ore is to be quarried in steps, the tenor checked by drill-holes, and account kept on the whole proposition in the manager's office. The price of copper will determine the ultimate horizon at which the steam-shovels will stop digging.

A visit to Bingham might prove a beneficial experience to some people I know, who insist that making cotton cloth and raising potatoes lie within the domain of legitimate business, but that all mining is a lottery.

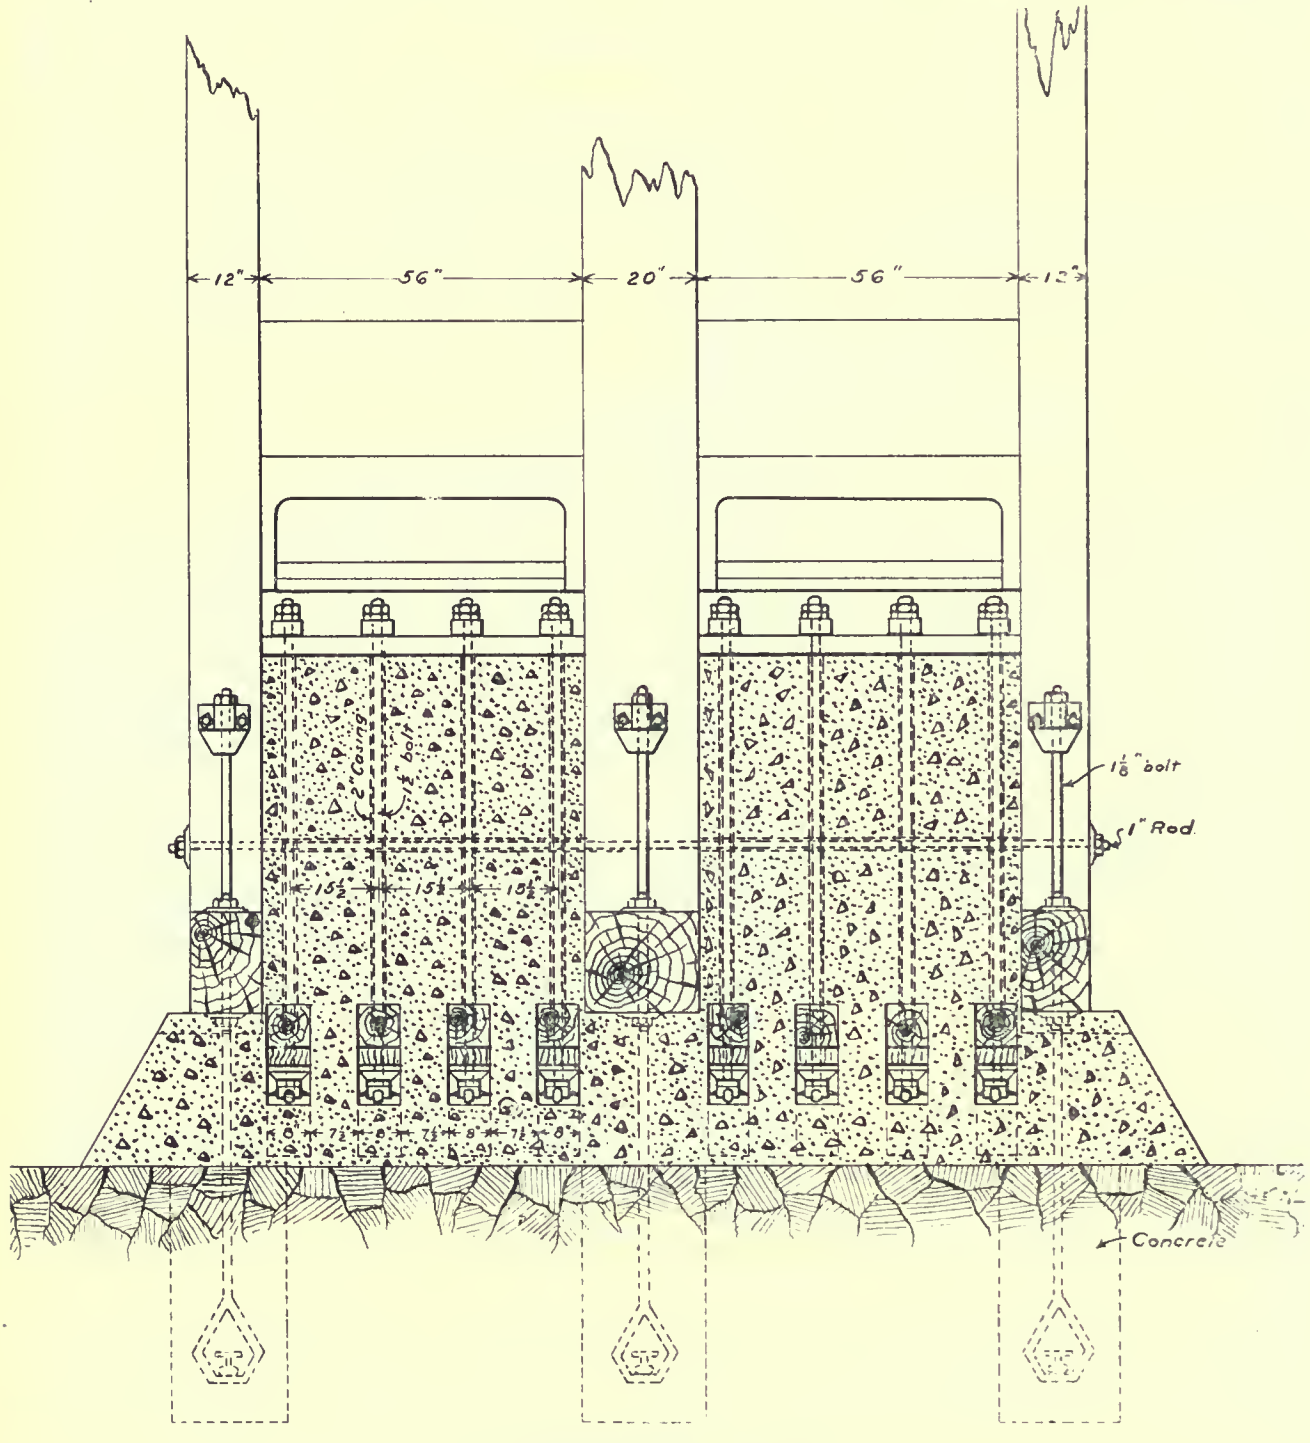
Battery Foundations of the Kuk-San-Dong Mill, Korea.

Written for the MINING AND SCIENTIFIC PRESS
By CHARLES D. KAEDING.

In the spring of 1905 this company, the Oriental Consolidated Mining Co. of Korea, began the erection of a 20-stamp addition to the 20-stamp mill at Kuk-San-Dong camp, installing concrete mortar piers and battery foundations. These were of a somewhat unusual type, owing to the local conditions, the most important of which is the distance from a base of supplies and a large foundry.

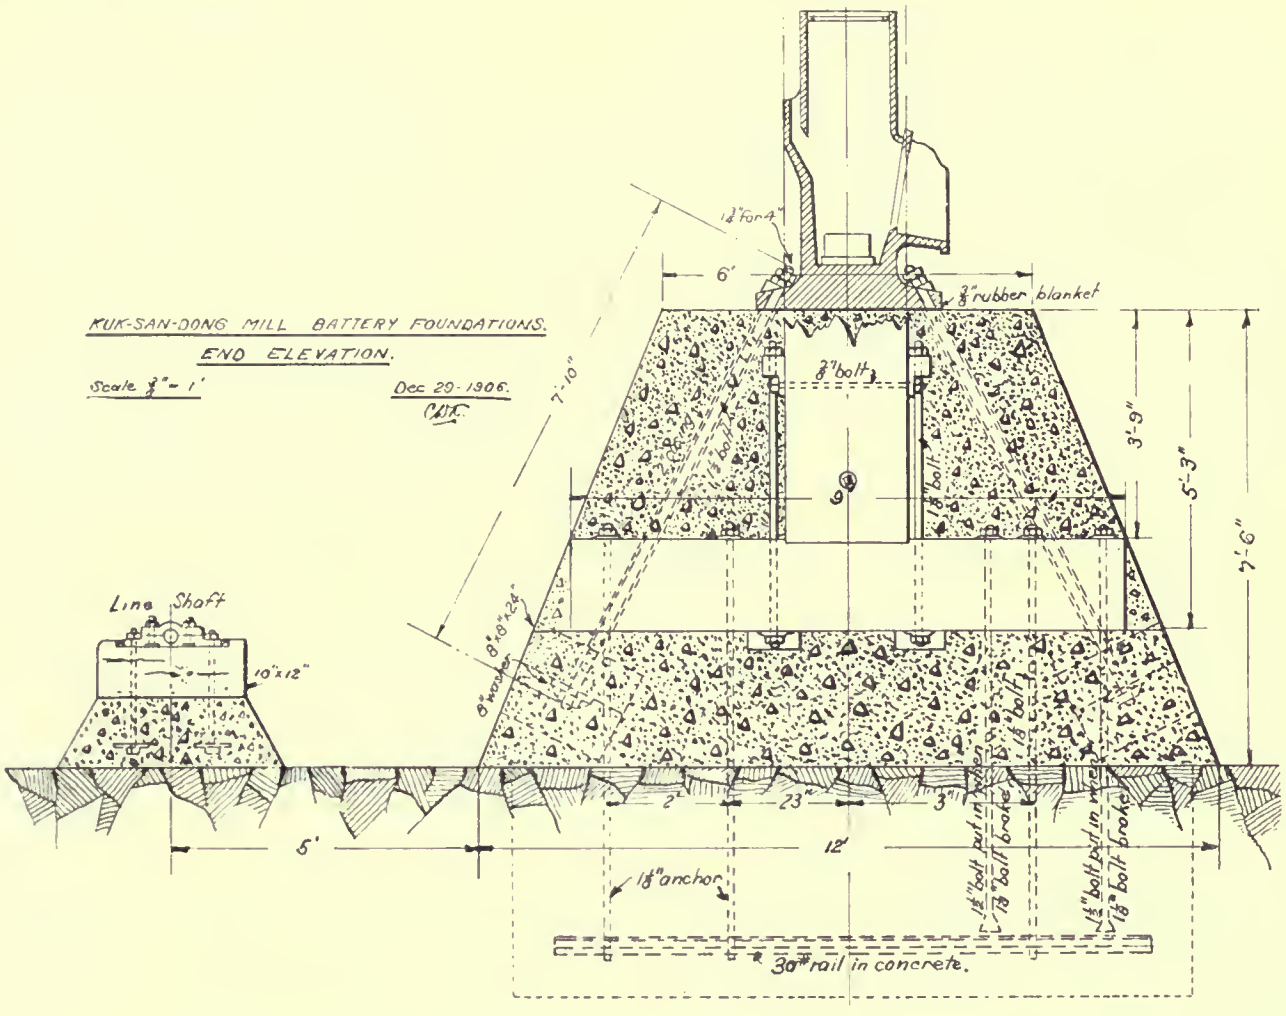
The machinery had been ordered by cable to be a duplicate of the twenty stamps in operation, and to have heavy mortars for concrete piers. The mortars supplied, pattern No. 48, Union Iron Works, of San Francisco, were designed for vertical anchor bolts 1¾ in. diam., the base being 36 in. wide by 56 in. long, and the weight, with liners, about 7,300 lb. The mortar was to rest on a ¼-in. rubber blanket placed directly on the concrete pier, and the anchor-bolts were to extend vertically downward 5 to 6 in. through 2-in. tubes to a pocket washer 8 in. square bedded in the pier, there being four anchors on each side. Foot-plates for battery posts were not sent, the manufacturers having designed a post extending below the top of the mortar pier to an 18-in. streak-sill resting on a shoulder of concrete, as shown in the front elevation.

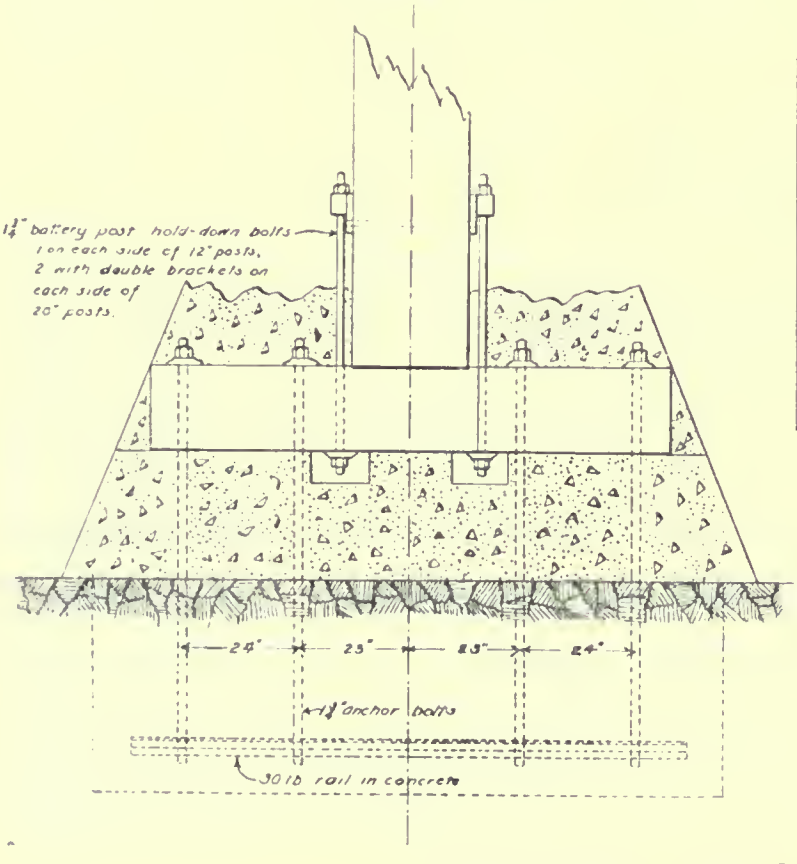
In view of the fact that a well placed concrete founda-

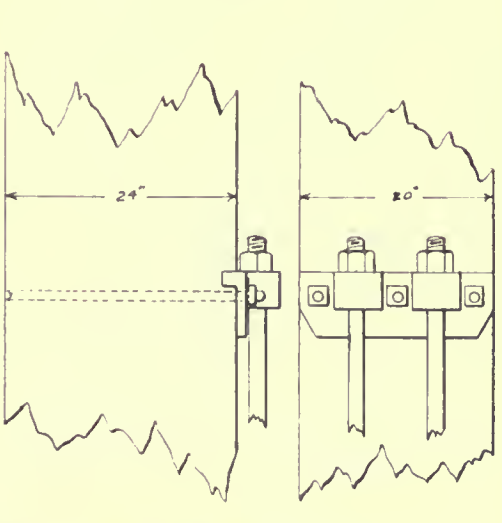


Front Elevation of Battery Foundations.

tion has no limit of life, it was considered expedient to so design all iron and wood-work in connection with the concrete piers that long interruptions, or the destruction and replacement of any part of the concrete-work as the result of breakage, would be unnecessary. To this end the vertical anchor-bolt holes in the mortars were chipped out, the bolts welded out to 7 ft. 11 in., and set diagonally, slipping in a casing; the pocket washers furnished by the manufacturers fitted at the lower end against a straining block set in an easily accessible pocket, and angle-







End Elevation and Details of Battery Foundations.

washers made at the camp with double nuts at the upper end. The piers were enlarged from designs furnished to 6 ft. at the top by 12 ft. at the bottom against 4 by 8 ft., and the shoulder carrying the streak-sill was lowered to 5 ft. 3 in. from the mortar-base.

The materials for concrete were carefully selected; the stone was a hard grano-diorite from the mine-dump put through a Blake crusher set at 1½ in., and was washed free of clay by a hose under pressure. The sand was ordinary river sand, granitic in character. The cement was the best grade of portland. An excess of water was avoided in mixing, and care was taken in tamping to insure a high density for the finished pier. The surface was left uneven over night, and when finally brought to the finished height was not capped with neat cement, but completed with the rough concrete. The piers were then seasoned for three months. The proportions used were as follows:

First	portion	1	cement	1	sand	5	stone for 3 ft.
Second	"	1	"	1	"	4	" " 2 ft. 6 in.
Third	"	1	"	1	"	3	" " 2 ft.

In my opinion this last mixture was richer in cement than was necessary, the 1—1—4 mixture containing sufficient mortar to fill all voids on the 1½-in. run of crusher-rock used.

This mill has been in continuous operation for fifteen months, and has developed only one fault; the anchor-bolts in the streak-sills and battery posts were not heavy enough, and have been replaced by 1½-in. bolts sulphured into the concrete, two bolts being put in the front portion of the streak-sill where there was formerly one. The accompanying sketch shows the changes suggested to remedy the weakness mentioned. The concrete-work has developed no signs of cracking or scaling, and will undoubtedly last many years.

The crushing capacity of the new 20 stamps has amounted to 1.3 tons per stamp-day more than that of the original 20 on wooden blocks, all other conditions remaining the same, over a period of nine months. The breakage of battery parts has been slightly less than in the original mill, and had been so small as to be a negligible quantity. The estimated cost of installing these batteries is about the same as that of a battery with wooden mortar-blocks and the usual type of foundations, amounting to $1,500 per stamp for the completed mill.

THE properties of nickel-steel that recommend it as a material for construction are toughness, great tensile strength, a high elastic ratio, and an ability to withstand to a high degree shock and repeated changes of stress. It is, in addition, of a more uniform structure than ordinary carbon steel, less subject to segregation, and less corrodible. The present limits to the tensile strength of simple steel are the brittleness and want of reliability under shock of the high carbon steels. The addition of nickel increases the strength and ductility of a steel of given carbon content and permits the use of a higher carbon and therefore stronger steel on account of the greater endurance under shock that nickel imparts to the steel.

SHAFT-SINKING.—The No. 1 shaft of the Brakpan mine, in the Transvaal, furnishes a record, for the first sod was cut on May 12, 1905, and by February, 1907, it was 2,002 ft. deep. The hoisting-engines were not on the ground until September 26, 1905, the shaft being then 60 ft. deep. The average has been 114 ft. per month, including all sorts of delays through bad ground, installation of pumps, and other troubles. The maximum sinking was 116 ft. in one month. The manager is Charles B. Brodigan, a graduate of the Royal School of Mines, London.

The Sherman Concentrating Table.

Written for the MINING AND SCIENTIFIC PRESS
By C. EVERARD ARNOLD.

The milling ore from the Daly-West mine at Park City, Utah, is silicious and exceedingly tough, showing masses of galena, pyrite, and zinc blende, a little chalcopyrite, and occasional patches of copper carbonate, its composition being fairly represented by the following partial analysis:

SiO_2	Fe	Zn	Pb	Ag
%	%	%	%	Oz. per ton
68.6	4.0	5.5	4.9	11.7

During the process of milling, in which the ore is subjected to various stages of crushing, screening, jigging, grinding, classifying, and table concentration, there results a product bearing 2% Pb and 9.83 oz. Ag per ton; screening tests on this material showing the following results:

	Per cent.
Passing 80 mesh and remaining on 100	0.3
" 100 " " " " 150	6.4
" 150 " " " " 200	5.8
" 200 "	87.5

In attempting to concentrate the valuable material contained in this product two types of concentrating table were used with unsatisfactory results as regards both work performed and cost of maintenance until the manager of the Daly-West mill, Frederick W. Sherman, devised a table that has been found to meet the requirements of the case, as I shall describe.

In the course of six days, assays were made daily of the feed, tailing, and concentrate, the averages of which are given:

	Pb	Ag
	%	Oz. per ton
Table-feed	2.00	9.83
Tailing	Trace	3.16
Concentrate	10.21	33.93

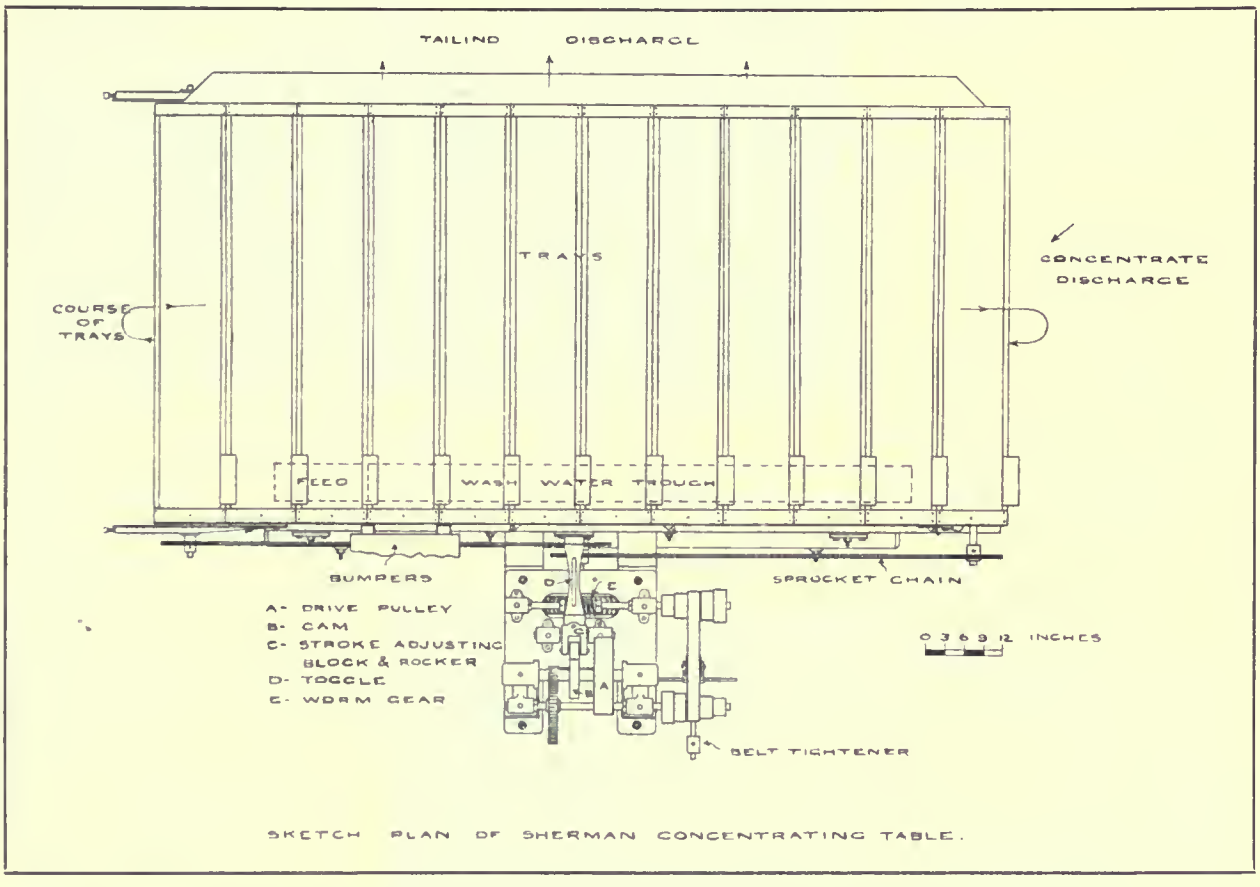
From which it is seen that practically all of the lead is recovered; and, as the table is effecting a concentration of approximately 5 to 1, the silver saving is 74%. Further, it was found that of the silver contained in the tailing, 31.55% was in the form of AgCl and this, as with slimed lead carbonate, it is practically impossible to recover by table concentration. The following are results of a screening test on the concentrate produced:

	Per cent.
Remaining on 100 mesh	Nil
Passing 100 mesh and remaining on 150	0.6
" 150 " " " " 200	0.8
" 200 "	98.6

Regarding the construction and operation of this machine, the concentrating area consists of an endless series of wooden trays (5 ft. 6 in. by 11¼ in.), somewhat similar to those used on the Wilfley slime-table, and these lie with their sides contiguous, the series being given a forward traveling motion, similar to that of a vanner-belt, by means of sprocket-wheels and chains, which are actuated by the head mechanism. In the accompanying plan the head mechanism is seen at the side of the machine, where, in conjunction with two compression-springs, it imparts a lateral reciprocating motion to the table-frame in addition to driving the trays forward. One of the principal features of the table lies in this head mechanism; not only can the length of the stroke be changed independently of other adjustments, but by means of a small 2-in. belt and a series of five pulleys ranging from 4¾ to 3½ in. diam., the rate of travel of the trays (and consequently the amount of treatment of the material) can also be regulated. This belt is held tight on its drive side by means of a lever and suspended weight, which safety device immediately causes the belt to slip if by any chance the travel of the trays is hin-

dered, thus precluding the possibility of a serious breakdown from that source.

The feed is delivered to the trays over a distance of 12 inches only along the table, and at this end of the machine the frame can be adjusted so that the trays receive a slight inclination, usually of about ⅜ in. per foot, the open end or foot of the tray at the tailing-discharge side of the table being highest. When the tray passes with its load from under the feed-box it comes in front of the two bumpers situated 12 in. apart and as it reciprocates against these, the heaviest particles of the material are caused to sink to the bottom and stratify, wash-water being meanwhile delivered to the heads of the trays along the table between the feed-box and the concentrate-discharge. After the tray passes the bumpers the grade



SKETCH PLAN OF SHERMAN CONCENTRATING TABLE.

gradually changes to the opposite slope, that is, the head or closed end now becomes the highest, thus enabling the wash-water to carry off the gangue, the final cleaning of the concentrate being effected on the steepest grade. The concentrate is then washed off by means of a spray from a perforated pipe, the tray returning underneath the frame to the head of the table for its next load. The length of stroke can be varied from ¾ to 1¼ in. and the number of bumps that each tray receives will be 182, 226, 270, 314, or 358, according to the speed at which it travels, the drive-pulley making 160 rev. per min. in each case.

This machine in the course of two months has been handling material at the rate of 7.05 tons of solids per day of 21 hours, repairs up to date having amounted to practically nothing; and although one cannot form an estimate of the cost of maintenance on the basis of the results of this one machine, it can reasonably be expected to be low, judging by the small amount of attention necessary when once the correct adjustment has been obtained. On the strength of the showing made by this single table, the Daly-West company has decided to immediately install 12 more in its mill.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The Talc-Schist sent by J. M., of Clovis, Cal., has no value.

The mineral sent by A. & C. from Coahuila, Mexico, is Garnet.

E. F. E., of Paris, Cal., sends the two antimony minerals, Stibnite and Stibiconite.

A specimen of brown andradite Garnet, Quartz, and Calcite carrying Pyrrhotite, Sphalerite, and Chalcopyrite was sent by J. C. H. of Globe, Arizona.

The specimen from Phœnix, Arizona, sent by C. M. C., is black Garnet, specular Hematite, and Quartz.

The rock sent by W. E. L., from Reno, Nev., is a volcanic Tuff stained with the iron mineral Chloropal.

B. C. O., of Olalla, B. C., sends: No. 1, Biotite and Epidote; No. 2, dark-green Hornblende and yellow-green Epidote.

The specimens marked 'Goldfield' are: No. 1, Breccia stained with Hematite. It should be assayed for gold. No. 2, a gauge of volcanic Tuff carrying much Pyrite; No. 3, Andesite.

The specimens from T. N. G. M. Co., Olighouse, Nev., are: No. 1, marked 'White Contact Outcrop' is a volcanic Tuff; No. 2, marked 'Shaft Rock 100 ft.' is an Andesite; No. 3, marked 'Shaft Rock 175 ft.' is an epidote-calcite-quartz rock and is probably an altered Andesite.

Letters of a Self-Made Miner to His New Foreman.—I.

Written for the MINING AND SCIENTIFIC PRESS
By MATT. W. ALDERSON.

My dear Tom:

I have decided to make you foreman of the Imalulu mine, and you will please arrange to begin service on the first of the coming month. You will naturally wish to know the measure of authority granted you and what will be expected of you in your new position.

You will have absolute authority over the mine, including the hoist and blacksmith shop, and all men employed therein. You will hire and discharge all men. I expect to make frequent trips through the mine, to take my own samples and keep in close touch with what is going on, but I shall have no orders for any of the men; so you may know there will be no conflict of authority.

I want you to get a force of good men under you—not the kind that requires constant watching and prodding. You may have noticed that the good thoroughbred horse needs but a word to cause him to walk off with his load with a quiet consciousness of power. If you wish to get the same work done by a plug, you must pound him on the back to get fair service out of him. There is just as much difference in men. Take your time to get good ones. We will stand by you if we have to hang up half the stamps in the mill. There is a mine just over the range where they hire every man who comes along in order to keep the mill running. One look at the crowd is enough. We don't want that kind.

You will be able to judge a good many men who apply to you by their appearance and the answers they give to a few leading questions. Take time to satisfy yourself by inquiry concerning any others. You have nothing to lose by the impressions getting abroad that you are particular in putting on new men. Some men 'hire and fire' and there is a steady stream coming in and going out of camp. I would rather it would be said of you: "He's slow about taking a man, but when he puts one on, he's there to stay."

There are several kinds of men you don't want. You don't want the spiritless man. You don't want the habitual rover, the man who never settles down in one place for any length of time. You don't want the great talker. You want a worker, one who is museled well in the shoulders and arms, not in the mouth. You don't want the kind of a man who thinks he knows better how to run a mine than you do—the professional agitator. You will have trouble enough without employing some one to make it for you.

You want men of good habits. I have mucked out after men who thought they could play cards in a saloon all night and do good work in the mine the next day, and I didn't need a car. I could carry out all the ground they broke in my pockets. You want to employ men who are stayers. It takes time to break a new man in to do the work just as you wish it done, and time is money.

I have always found a man who saved part of his earnings a good man to employ. This does not say that men who do not save will not be good men. I have had splendid workmen whose money went from them after pay-day like water through a sieve. That a man does not save is no reflection on his character. The civilized man is known by the grandeur of his wants and when a man doesn't save, it only shows there are other things he prizes more than he does money. This is all right, if the things he values are good in themselves. But some men are exceedingly wasteful and extravagant and such persons in some places in the mine will require your constant care and oversight.

You will be told that if you want good miners you must get Cornishmen. Don't you believe it. No one country has a monopoly of brawn or brains. Of four premium men, not born in the United States, whom I had at one mine, one was a native of Germany, one of Sweden, one of Nova Scotia, and one of Switzerland. There is many a capable, skilled miner among the Cornish, but you will get better work out of your men if they feel that you are not prejudiced in favor of some one nationality, but that you judge every man on his merits, regardless of where he may have been born.

It is a rule of the Miners' Union that all miners must receive the same remuneration, regardless of their being skilled or unskilled; but it is no fault of the Union if you choose to give employment to poor workmen or to men who will cause you trouble. "But," I hear you say, "every mine can't have a force of picked men." Yes, it can, if it so chooses. One must not make the mistake of thinking that in choosing good men every foreman will take the same type. I have seen a force of very superior men gathered by one foreman go all to pieces in a few weeks under his successor. The new man was better educated than his predecessor; he was more intelligent, but he was lacking somewhat in those elements of character that make the born ruler. He thus failed to dominate his men. But he made a good foreman, nevertheless, and had good men under him, but the keen observer would detect that the new men put on were unassuming. They did not have as pronounced an individuality as the men who quit. Then, again, tastes differ in this world. Give one man certain work to do with a team and he will choose the best American horses he can get. Another will think bronchos "just the thing," and a third will take cayuses. For our work I want you to have thoroughbreds. There are plenty of persons who will be satisfied with the men you do not accept and undoubtedly there will be many good men among them. To make a success as a foreman you must have men who find it a pleasure to recognize your leadership. No one can pick such men for you. You must size up the applicants and choose for yourself.

Sincerely yours,

TIMOTHY STRONG.

THE United States Forest Service has been making a thorough study of the influence of moisture on the strength of wood. The results of its investigations show that the relation of moisture to strength follows a definite law. Proper drying greatly increases the strength of all kinds of wood, the amount of increase depending upon the species and the dryness. For example, the strength of a piece of unseasoned red spruce may be increased over 400% by a thorough drying at the temperature of boiling water. Strength decreases again, however, as the wood re-absorbs moisture. Air-dried wood, protected from the weather, and containing 12% moisture, is from 1.7 to 2.4 times stronger than when green, according to the species. Stiffness is also increased by drying. These conclusions, however, are drawn from small-sized pieces, not exceeding 4 by 4 in. cross-section. Large timbers require years of drying before the moisture is reduced to the point where strength begins to increase. More or less checking always occurs when large timbers dry, and if this checking is excessive it may cause enough weakness to counterbalance the strength gained by drying. Consequently it is not safe to assume that the average strength of large so-called seasoned timbers is much greater than that of green or wet ones.

Mining in Honduras.

Written for the MINING AND SCIENTIFIC PRESS
By HORACE G. NICHOLS.

Those engineers to whom the possibility of non-persistence of veins in depth gives an additional zest to their work, will find plenty of scope in Honduras. Such men will not be dismayed by sudden set-backs in the course of development from pushing their work to a logical conclusion.

Porvenir Mine, 40 Miles From the Coast.

The truth of such a characterization will be more fully appreciated after experience with a number of abandoned mines, which are monuments of want of persistence, in men, rather than veins.

The country consists essentially of plutonic and volcanic rocks, but these are often so altered as to produce metamorphic varieties requiring care in classification. Not much prospecting work has been done really deserving of the name. The richest parts of Honduras are as yet all but unknown. The northern interior is not easy of access, and, in spite of excellent specimens, rich in copper and gold, that are continually being brought from that region, a mine able to pay its way from the first strike of the pick has yet to be found and the capital required during initial stages of development has not been forthcoming. Some instances there are, however, where there has been no lack of funds provided, and, in such instances, returns have not been wanting; but too much has been left to native work and haphazard methods. More systematic prospecting is wanted, conducted by qualified men.

There are too many prospectors of an irresponsible class to whom the work of exploration has been committed; they have damaged the country's reputation by their facile way of explaining their inability to follow a faulted vein, by referring to it as "another of those wedge-shaped surface veins."

Numerous examples occur, in old Spanish workings and others of more recent date, of want of persistence and lack of technical knowledge, combined with unpreparedness for dealing with the inevitable conditions, where abandonment has suggested the non-persistence of the ore deposits.

In one mine, a bonanza had been worked to a depth of about 200 ft. from the surface, where it came to an end between two converging faults. On the upper levels it had been worked for a length of 150 ft., with excellent results; but, although it was apparent that this orebody was included between the two faults, no attempt was made to look for the vein on the other side and only when the end of the ore had come, was the necessity for prospecting realized. In this case it was found, after passing through the fault, that the whole country had been shifted by three successive movements and the vein was actually thrown for over 300 ft. The final fault-movement presented some interesting features. The vein, having a north-south strike, and dipping 50° E, had been cut off on the 100-ft. level by a fault, which may be called No. 1, and which had a strike N 80° E and dip 80° NW. Prospecting showed no continuation of the vein on the north side of this fault for 80 ft. east and west. A cross-cut, however, on the 200-ft. level proved the continuation of the vein beyond this fault and but slightly dislocated. Upon driving north for 60 ft. on this portion of the vein, a second fault with strike N 65° E and dip 48° NW again cut off the vein. Associated with all the workings was a third fault, No. 3, striking N 27° E and dipping 56° NW which was well-known as producing but a slight throw of the vein, and in every instance where this fault had been encountered in the stopes, intersecting the vein, a small cross-cut to the east on the north side of the fault was sufficient to pick up the vein again. Just before meeting the No. 2 fault this No. 3 fault had again been encountered and passed through. The No. 1 and 2 faults came together just above the No. 1 level on the line of strike of the vein. Although the reason for the existence of the vein between the No. 1 and 2 faults on the No. 2

An Example of Native Mill-Construction.

level—while there was no trace of it on the No. 1 level beyond the No. 1 fault—was not understood, a cross-cut east was driven on the No. 2 level after driving north from the No. 2 fault some 40 ft. and matters were apparently still further involved by encountering in this cross-cut the No. 3 fault, in such a position as indicated a very small throw from its old line of strike. It was realized that something more than a mere lateral movement must have taken place, inasmuch as the No. 3 fault had already been passed through at its intersection with the vein upon this level, and therefore it was to be expected that at any point north of this intersection, the vein should certainly be cut first, in going east. A close study of the ground in a small cross-cut that had been made just beyond the intersection of the vein and the No. 3 fault (where the No. 2 fault was first found) showed an appearance on the under side of the No. 2 fault, suggesting an extensive upward sliding movement, 'fraying' the rock on the under side of the No. 2 fault, and in following this out, it was seen that several conditions might be explained. In the first place, the vein dipped east and therefore in being raised vertically from a lower level it would come into a position relatively east to its position upon a higher level. The No. 1 and 2 faults came together just above the No. 1 level, and so the ground between them upon this level was so broken and disturbed that no continuation of the vein was found in place, but the 'drag' was found along the line of fault to the east. Below, on the 200-ft. level, with the 60 ft. of ground between the faults, the vein, although much shattered near the No. 1 fault, continued still. Next, the finding of the No. 3 fault before the vein in the east cross-cut was explained, for, as both it and the No. 2 fault dipped NW, its apparent throw by an upward movement of the ground on the latter fault would of course be far less than the apparent throw of the vein, which dipped 50° east, and it was calculated from these considerations principally that all the ground on the north side of the No. 2 fault had been brought up from a vertical depth of about 150 ft. and this would call for a further distance of 200 ft. to be cross-cut beyond the No. 3 fault in order to get the vein. This work was done and the vein was found, thereby affording most useful data for the prosecution of work below this lowest (200 ft.) level. On this property, surface workings over a distance of 2,000 ft. have given some excellent results and point to a continuance of the main vein, but in territory divided by disturbing faults of such frequency and magnitude as to make an extensive system of preliminary underground development essential to economic working of the mine. The bonanza, mentioned above, carried some ore as rich as 10 oz. gold per ton, and was characterized by plentiful sulphides. Often no 'color' was obtained in panning, but a free-milling extraction was obtained on the plates, 81% being obtained from ore carrying over 7% concentrate, which accounted for a further 9.5% extraction. Owing to some copper in the tailing, the economic treatment of the residue was not undertaken.

In this particular instance the situation was saved by the plucky persistence of an English company, which owned the property; but this is an excepton to the general rule obtaining in the country, for, in most instances, by trusting to native guidance, the necessity for energy in pushing development work is entirely lost sight of, and the first fault to affect the vein and baffle the skill of the native mine foremen, sounds the death-knell of the mine. In only one mine in the whole country has an orebody been prospected to a depth of over 500 ft., and in that case the results have beeu eminently satisfactory.

The fallacy of trusting to native methods is strongly demonstrated in the case of another group of mines known to me. In these work had been done for twelve or thirteen years without having recourse to proper technical advice. Reports were made showing the cost of mining to be about $15 per ton; upon this were founded estimates of great possibilities and money was freely supplied. From time to time accounts were rendered, which, while admitting no profit, showed that the cost of working was well within the prescribed limit and every bunch of ore that gave good returns was brought forward as typical evidence of progress and a just foundation for expectations. Assays were made occasionally, and the best were always reported. A day's work was taken as typical of a month's operations and a mill-run for a few hours made everyone happy, so that a cablegram was despatched to the effect that the mill was working splendidly, and from reading these reports, which from the native standpoint were a representation of the actual operations, the idea was conveyed that strenuous efforts were being made, the concern being worked upon a scale that sooner or later must produce results in accordance with the promise suggested by the rich pockets.

The reality was in painful contrast. The actual tonnage milled altogether was but 2,000 tons. A network of drifts and cross-cuts at intervals of 30 ft. and less honeycombed the vein where it was easily accessible from adits and a shaft, upon which all energies should have been bent from the outset, was abandoned on account of water. The actual value of the ore milled was no more than $12 and the net loss per ton was well over $80 in operating expenses alone. Thls whole condition of affairs was brought about by no willful misrepresentation, but was due to lack of appreciation of the vast difference between what really constitutes a mine and the idea of a mine as conceived by those to whose philosophy provision for the future is, and always has been, foreign.

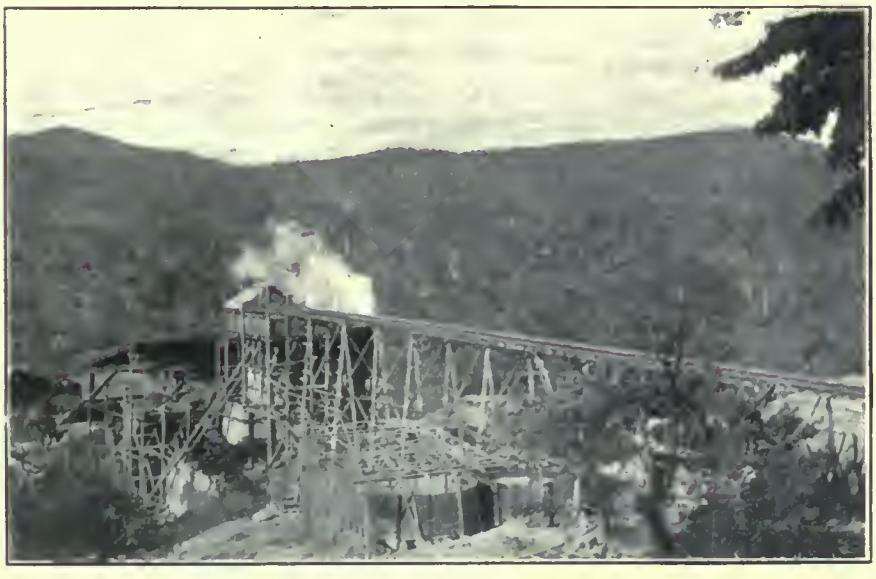
In another mine near the West Coast, in a country characterized by rhyolite and basalts, a strong vein of clean quartz is broken at the surface by an intrusive body of eruptive rock for a distance of 1,000 ft., continuing on either side with a bold outcrop. On each side of this break for 400 to 500 ft., there is a curious transverse banded structure, the quartz in places being banded with silicified rhyolite. The ore in this vein appears to have a close relation to the proximity of this intrusion, a marked improvement being noted at the intersection. The present workings of this mine are down to sea-level, and, so far, the quartz is much honeycombed, and no indication of any economic results of this leaching have been observed. This vein is about 15 ft. wide, and carries gold and silver, making a low-grade ore. It is mentioned as instancing the possibility of good results with proper management.

It is often stated that labor is cheap in Honduras. It would be more correct to say that laboring material is cheap, and with proper supervision can be utilized to do cheap work. The want of application, of steady purpose, in the native character makes itself felt in no way more forcibly than in the efficient consummation of mining work requiring skill and persistence in its execution, and this is especially so in such work as is foreign to the time-honored ideas of the country. On the other hand, given a satisfactory organization and proper handling of the men, where provision is made for providing the necessary guidance in all details, there is no doubt cheap work can be done.

The native lives from hand to mouth, and is disinclined to recognize any inducement beyond his immediate needs. It is said that this is due to political conditions, but in this matter, as also in the encouragement of the sale of native liquor, out of which the Government draws one of its principal sources of revenue, the mining economist, seeking to improve mining conditions by

striking at the root of the evil, will do well to remember the Spanish proverb, "*Del mal el menos.*"

It is common to be told in Central America that before it is possible to do anything, the customs of the country must be observed, that all ideas of getting anything more out of the natives than that to which they are accustomed, must be abandoned, and that one must learn to adapt oneself to the easy-going round of tropical existence. On the contrary, I believe that while using to the full all advantages to be secured by native help, if success is to be achieved a struggle must be maintained to lead, not to follow, in the way taught by experience elsewhere. As a certain class of freight-cars may be more adaptable to a particular kind of freight, so is the native best suited to manual work in the tropics; but it is not more futile to expect those freight-cars to travel across the continent without a locomotive than to expect to succeed in mining here by leaving the prosecution of the work to native hands. If it is stated that no white man can long stand such a strain, then let it be for a short time, with opportunities provided for periodical recuperation.



The Mill of the Transito Mining Company.

Approaching the question of costs, it becomes difficult to make any statement in average figures. Conditions vary so much in different parts of the country, and even in the same place at different periods of the year that in a community where mining is not looked upon as a steady pursuit, the hire of labor suffers from many fluctuations. It is, however, possible to state within reasonable limits the average cost per day for the different classes of workmen, miners, shovelers, mechanics, etc., but when it becomes a question of figuring from such data the cost per foot or per ton, a difficulty arises. This, perhaps, cannot be better described than by stating the cost in specific instances.

A shaft 8 by 14 ft. was being sunk vertically as the first step in developing a mine near the West Coast and the cost of sinking was 15 *pesos* or $6 per foot without timbering. The rate of progress was 5.5 ft. per month. As it was essential that this shaft should be sunk 100 ft. vertically within three and a half months, arrangements were made and inducements were offered for expediting the work, but directly the natives saw that they were wanted to work, trouble began. The work was done but at a cost, without equipment, of over $50 per foot. Thus it will be seen that the time factor is of prime importance.

The necessity of doing a little work occasionally is recognized among the natives for the supplying of their modest wants and they are accustomed at odd times to hire themselves for making fences, sowing corn, etc. The pay for such work among themselves is very small indeed. Take the case of the construction of fences around corn patches. A good form of native fence is made with rough branches supported on forked posts at one end, the other end resting on the ground. When well made these fences will last for some time. The ordinary day's task in such construction is 24 *varas* of 33 inches in length, the fence being about four feet high. A day's pay is at the most 75 *centavos*. The cost becomes approximately one *centavo* per running foot or 250 ft. for one gold dollar. Let, however, a foreigner hire labor for the construction of a post-and-rail fence or any other kind, not known to the native, and the price will be very different indeed; and so it is with mining. In the case of the shaft mentioned above there had been no pressure brought to bear to hasten the work and no regular gang was kept employed. The native foreman in charge was content to depend upon such promiscuous applications for a day's or half a day's work as might chance be made to him, with the result as stated. Immediately, the aspect of the undertaking was altered and instead of offering a convenient opportunity to earn a few cents as desired, the work was regarded as a hardship for which extra compensation was needed. This disinclination to commit themselves to more work than they may feel inclined to do at any time is also

Cyanide Plan at the Transito Mine.

shown by another instance in which a contractor was offered a higher rate per foot for sinking a shaft should he exceed a certain footage per month. He refused the offer and at the end of the month he had accomplished in his own way exactly the limit specified. It will be seen then that the cost of an undertaking will depend entirely upon supervision and organization and the capacity for using to the best advantage the class of labor available. Such labor costs about as follows: Miners, 1 *peso* per day; shovelers, 50 to 75 *centavos;* mechanics, 1.50 to 3 *p.*; firemen, 1.50 *p.*; blacksmiths, 1.50 to 3 *p.*; timbermen, 2 to 2.50 *p.*; carpenters, 2 to 2.50 *pesos.*

The native master-mechanic or mine-foreman is not recommended. The instance already quoted sufficiently describes the irregularity of which such men are capable, perhaps unintentionally, but none the less productive of immense confusion, and, if allowed to go on, disastrous results. A case came under my notice in which a contract was let for driving a tunnel. The cost was reported as being $3.50 per *vara*, or yard. The unreasonableness of such a cost leading to close investigation, elicited the information that as a matter of fact this particular piece of work was costing $27 per foot, the difference being caused by sundry allowances for a missed hole, perhaps, or a piece of hard ground, or delay in laying the track, or almost any trivial excuse, the excess being cheerfully charged to 'mine expense,' or some other sink for promiscuous expenses.

Undoubtedly, what is required is to strike the happy medium by providing foreign shift-bosses to direct the working of gangs, and able to provide what is lacking in foresight and persistence while using the labor that the country provides.

Prospecting during the greater part of the year in Honduras is not attended with as much difficulty on account of vegetation as might be expected. The duration of the 'dry' season varies with the locality, but as far as the western portion of the Republic is concerned, it may be said to commence in November. No new vegetation commences to grow much before July.

The timber and water supply also varies considerably in different parts of the country. Where wood is plentiful, it can be had at a reasonable cost, and makes good firewood. Where it has not to be hauled for more than a couple of miles, the cost delivered at the works is not more than about $1 gold per cord. The native cord is equivalent to about 0.6 of a standard cord, making an equivalent of about $1.60 gold for a standard cord.

Many of the native woods fit for fuel make excellent mine timber, but, where the difficulties of access are not too great for construction purposes, it is more economical to import lumber on account of the great hardness, and difficulty of working, the native timber.

On the whole the climate is not altogether unhealthy, and with proper care, good living, precaution regarding mosquitoes, drinking water, and getting wet, there is but little fear of serious illness in the worst parts; in the hills the climate is delightful, though hot in the middle of the day.

MINERALS AND PRECIOUS METALS are said to abound in Roumania, but thus far only salt and petroleum are obtained. The petroleum industry is advancing rapidly and will probably become one of the most important sources of revenue. Large tracts of supposedly petroliferous lands are as yet unexploited, and other sections are only just beginning to be worked. At present the production of petroleum is chiefly from the district of Prahova. There is said to be $30,000,000 capital invested in this industry, mostly by German, Dutch, French, Italian, and American interests.

Decisions Relating to Mining.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

A demand made by a miner to the drivers for props, on several days prior to the day of the injury by the fall of a portion of the roof of the room of the mine in which he worked, was held to constitute a sufficient demand on the mine manager as required by statute, where it appeared that the mine manager had instructed the miners to make requests for such props direct to the drivers, with whom they came in direct contact, it being inconvenient on account of the size of the mine to make such request to the mine manager in person.

Donk &c. Coal & Coke Co. *v.* Lucis, (Ill.) 80 N. E. 560. (Feb., '07.)

A miner whether working as a servant of the mine operator, or working in the mine by invitation, is held to assume the risks incident to such work; but increased risks caused by the negligence of the operator are not regarded as incident to the business, and are not assumed by the miner.

Birmingham Min. &c. Co. *v.* Skelton, (Ala.) 43 So. 110. (Feb., '07.)

A gift of a certain sum of money to the governor of a province in Panama to pay his expenses to the capital to confer with the president of the State, concerning the grant of a mineral concession to the persons furnishing the money, would not be the use of money for an unlawful or immoral purpose; and especially where the agent of such persons furnishing the money was advised that the president of the State made it a rule not to grant a mining concession in an outlying province without having first personally consulted the governor of the province.

Allen *v.* O'Bryan, 103 N. Y. Supp. 125. (March, '07.)

A mine owner is not relieved from liability for his neglect to perform a statutory duty to prevent the accumulation of dangerous gases, which led to an explosion, because there was another efficient cause contributing to the accident for which a recovery could not, under the declaration, be had.

Wilmington Star Min. Co. *v.* Fulton, 21 Sup. Ct. 412. (March, '07).

In an adverse suit to determine the title to a mining claim the rules governing ordinary ejectment suits, that mere prior possession shall constitute a basis for recovery, does not apply, but the rule is that the defendant, as the plaintiff must recover on the strength of his own title. And the Land Office is not bound to recognize the finding of a court for a defendant, unless it be upon proof of right of possession; and any local court which proceeds in defiance of this condition simply imposes on the litigants the probable penalty that the Land Office will not regard their conclusions thus reached in disregard of the Act of Congress. All the finding that the Land Department asks from the Court is: "Who, upon the merits, has the right of possession?" All other findings are said to be superfluous and an invasion of the jurisdiction of the Land Office; this is true because "it remains in every case for the Land Department to determine all other questions touching the right of patent."

Upton *v.* Santa Rita Min. Co., (N. Mex.) 89 Pac. 275. (Feb. '07).

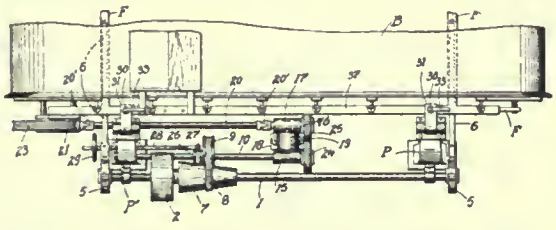
A forfeiture of a mining claim for failure to do annual work can be established only upon clear and convincing proof of such default proved against the former owner by the party assailing his title. But where the owner has failed to make and file the proof of labor required by statute, such owner was held not entitled to invoke this rule, for the reason that the statute places the burden of proof upon him to show that such work has been done according to law, and not upon his opponent to show that it has not been done.

Upton *v.* Santa Rita Min. Co., (N. Mex.) 89 Pac. 275. (Feb. '07).

MINING AND METALLURGICAL PATENTS.

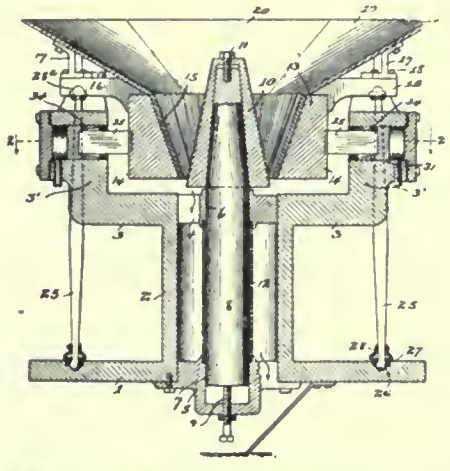
Specially Reported for the MINING AND SCIENTIFIC PRESS.

VANNER.—No. 850,415; George O. Bradley, Salt Lake City, Utah.



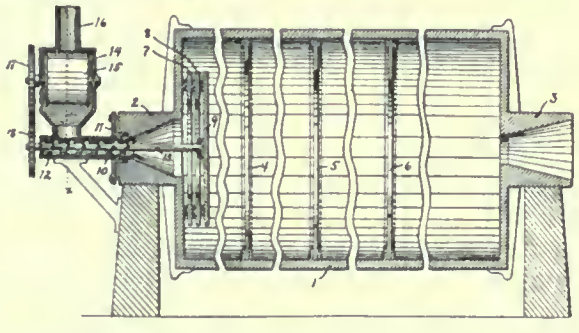
In a vanner, a drive-shaft, a cone-pulley carried thereby, a second pulley co-operatively connected thereto, a shaft for said second pulley, capable of oscillation about a fixed point, a jointed shaft located adjacent to said oscillating shaft, and having a section capable of conjoint oscillation with the oscillation shaft, intermediate gearing between the oscillating and jointed shafts, located contiguous to the point of oscillation of the shafts, a vanner-belt, and suitable gearing between the jointed shaft and belt for imparting motion to the belt.

GYRATORY CRUSHER.—No. 850,491; Oliver C. Redding, Chicago, Ill., assignor of one-half to William K. Kenly, Chicago, Illinois.



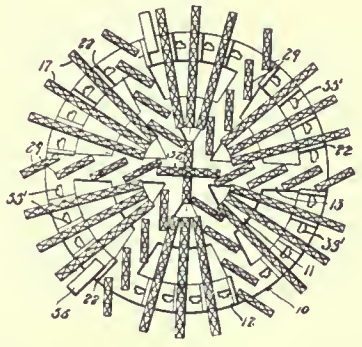
In a gyratory crusher, the combination with a central crushing-head, of a surrounding crusher-jaw supported to move bodily in a plane perpendicular to the axis of the central crusher-head, and means for gyrating said surrounding crusher-jaw member in its said plane of movement.

PEBBLE-MILL.—No. 849,730; George S. Emerick, Nazareth, Pennsylvania.



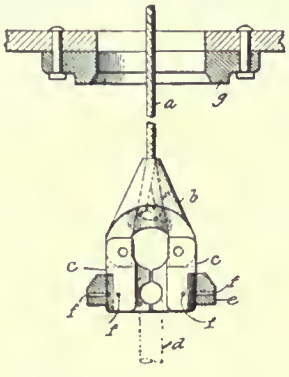
In combination in a pebble-mill, means for separating and feeding material into said mill, consisting of a feed-spout delivering upon a feed-roll, an inclined screen in close juxtaposition to the surface of said feed-roll, a tailing-spout, a worm-casing and a worm adapted to rotate therein, and means for reducing the material fed into said mill, said means including a plurality of transverse, annular flanges progressively increasing in depth from the feed to the discharge end of said mill, whereby the passage of material through said mill may be retarded.

TUNNELING-MACHINE.—No. 848,107; John P. Karns, Boulder, Colo., assignor to The J. P. Karns Tunneling Machine Co., Boulder, Colorado.



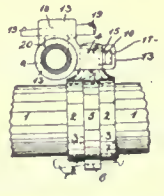
In a tunneling-machine, the combination with a revoluble bit-carrying head, of a rifled shaft connected thereto, a casing surrounding the shaft at a point adjacent to the head, and having diametrically opposed projecting arms, jack-screws arranged in the arms and designed for engagement with the tunnel-wall, a ratchet-wheel arranged within the casing, and having an opening for the passage of the rifled shaft, and a pawl carried by the casing and engaging the ratchet-wheel.

DETACHING-CONE FOR MINE AND OTHER ELEVATORS.—No. 845,177; George Killian, Scranton, Pennsylvania.



In a device of the class set forth, a hollow cone in which is adapted to be secured the lower end of the hoisting-cable, a pair of depending jaws pivotally attached to the lower end of the cone at opposite sides of the hole in the same, the lower ends of these jaws being adapted to swing outwardly, and their inner faces being adapted to receive and engage the cage-hanger, a ring or band surrounding the jaws at their lower ends and serving to hold them in engagement with the cage-hanger, frangible pins fastening the ring to the jaws, in combination with a stripping-ring supported above and in line with said ring or band.

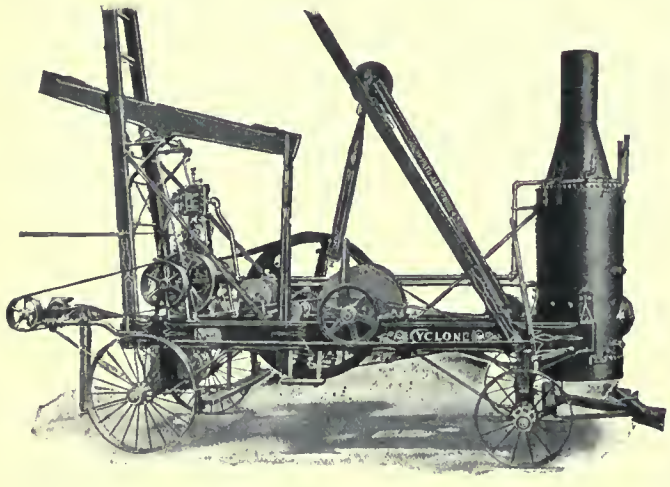
MEANS FOR MOUNTING ROCK-DRILLING MACHINES OR ENGINES.—No. 850,885; Henry Hellman and Lewis C. Bayles, Johannesburg, Transvaal.



In means for mounting a rock-drilling machine or engine, in combination, an engine-clamping means comprising a pair of sleeves surrounding the machine or engine, a third sleeve disposed between those already named and also surrounding the machine or engine, a key engaging all three sleeves and adapted to pull the last-named sleeve in a direction opposite to the pull upon those first named, and a column-engaging projection secured to said engine-clamping means.

A Combination Prospecting Drill.

Within the past year a complete combination drill has been placed on the market handling core, hollow rod, and cable tools, or any two of the systems. This machine has been perfected to meet a demand where the conditions cannot be well met with one tool equipment, or where the character of the formation is not known. The drilling elements employed are in no way an experiment, but the design and construction of the machine make it possible to operate any of the systems successfully, and this appeals strongly to the experienced prospector, who has encountered conditions with one type of drill that proved a failure, while the proper equipment to meet the particular conditions could have been highly successful. The cost of the drill-work can be reduced in many instances; it may be desired to obtain



cores of strata at considerable depth, and simply a record of the depth, thickness, and character of the overlying strata; the drilling can be started with the churn-drill, which brings the material out in cuttings, and continued down to a point where it is desired to obtain cores; the core attachment is then put to work and cores removed, getting the same practical result as by using a core-drill from top to bottom, yet at a great reduction in cost as compared to core-drilling had the core-drill been used from top to bottom; also on ground where bedrock lies at great depth, and a large amount of soft material must be passed through, or the material is badly broken, as is the case in many places. There are no tools that will work so successfully in this kind of material as churn-drills of the hollow rod or cable type. A purely core-drill is not so well equipped for driving and pulling long strings of drive-pipe as is the churn-drill; neither will it drill so rapidly in soft formations, such as shale or similar material. Holes can be sunk rapidly with these equipments and much time saved, which is frequently of considerable importance. The outfits are built in a number of sizes and styles, with various equipments to meet the conditions prevailing in various localities. They are built by the Cyclone Drill Co., of Orrville, Ohio, in connection with their standard well-drilling and prospecting outfits.

Trade Treatises.

THE CHROME STEEL WORKS, of Chrome, N. J., has issued a new catalogue describing the Canda tempered steel jaw plate for crushers; also chrome steel wearing parts for cement-grinding mills. We have also received a particularly handsome pamphlet describing the Canda self-locking cams, tappets, and boss heads, under the title of 'Stamp Mill Parts.'

Technical Schools.

We have received the *Quarterly* of the Colorado School of Mines, containing views of the college buildings at Golden, and field-trips of the students.

Commercial Paragraphs.

THE MOUNTAIN COPPER CO. has removed its offices from Oakland to 150 Pine St., San Francisco.

ROBERT W. HUNT & CO. have moved their offices from 66 Broadway to the new West St. Bdg. at 90 West Street, New York.

THE GENERAL ELECTRIC CO. states that its executive office for the Coast will be henceforth on the tenth floor of the Union Trust Bdg., San Francisco.

J. S. WATSON, manager of the Link-Belt Co.'s drive-chain department, sailed for Europe on April 25. While abroad Mr. Watson will visit the chain-making plant of Hans Renold, at Manchester, England.

THE RICHARDSON SCALE CO., of New York, makers of automatic weighing scales, have removed from the Park Row Bdg. to No. 3 Park Row, where more room, necessitated by their greatly increased business, is available.

THE San Francisco office of the GENERAL ELECTRIC CO. is now in the Union Trust Bdg. Since the fire, the office has been in the Union Savings Bank Bdg. at Oakland, large temporary warehouses having also been erected in the same city.

THE MIDVALE STEEL CO. of Philadelphia, Pa., announce that on May 1 they moved their general sales office for the Pacific Coast to the Monadnock Bdg., San Francisco, where they will be permanently located hereafter. Jas. C. H. Ferguson is Pacific Coast sales agent.

THE RICHMOND MACHINE & IRON WORKS is a new company that has established a large and well-equipped machine-shop at Richmond, in Contra Costa county, California. Richmond is situated on deep water at the terminal of the Santa Fe railroad, with spur tracks from the main line of the Southern Pacific.

THE MINNEAPOLIS STEEL & MACHINERY CO. has opened a branch office at 262 Commerce St., Dallas, Texas, under the management of J. P. Greenwood. The large demand for Twin City Corliss engines and Muenzel Producer gas engines in this territory made it necessary to open an office in that State, so as to take care of the increasing business.

THE RISDON IRON WORKS is making an improvement on the Johnston concentrator, and it is known as the new Standard Johnston machine. A large number of them are in use in the big mills of the Utah Copper Co., and the Boston Con. Copper Co., in Utah. This new Johnston machine is considered one of the best tables on the market.

THE INGERSOLL-RAND CO., 11 Broadway, New York, has issued a booklet of 20 pages, with 11 illustrations, describing the new Temple-Ingersoll electric air-drill. This novel device not only completely solves the problem of employing the electric current in the driving of rock-drills, but avoids entirely the conditions that make the successful employment of the electric-drill impossible. The drill is air-operated, with advantages of its own, especially in the increased force of the blow struck and the great saving of power.

Catalogues Received.

GEO. E. WOODBURY, of San Francisco, Cal., has just published Bulletin No. 1, on the 'New Woodbury Concentrator.'

THE C. O. BARTLETT & SNOW CO. of Cleveland, Ohio, is mailing to the trade Catalogue No. 16, concerning Mechanical Dryers.

THE ALLIS-CHALMERS CO., of Milwaukee, Wis., has issued Bulletin 1,423, describing Gates breakers with short head and concaves for fine crushing.

THE CYCLONE DRILL CO., of Orrville, Ohio, has issued a 100-page catalogue describing its prospecting machinery for use in coal, water, oil, gas, mineral, and placer mining.

The Jeffrey Manufacturing Co., of Columbus, Ohio, sends us illustrated catalogue No. 57 B, describing Jeffrey conveying machinery for sawmills, lumber mills, and wood-working industries.

Editorial.

A CONFERENCE of the heads of the State Geological Surveys has been called by Mr. George Otis Smith, the director of the United States Geological Survey. This conference will take place at Washington on May 20, and it is likely to become a regular event, having been found to be most useful. The subjects to be discussed include geologic, hydrographic, topographic, and statistical work. In Colorado the legislature has passed the bill for a State Survey, and Mr. R. D. George has begun work on a revised geological map of the State.

COBALT has a local branch of the Canadian Mining Institute; it has started with 50 members. A. A. Cole is chairman and George D. Hardy is secretary. The first meeting was devoted to a discussion of the paper by Mr. C. R. Van Hise on the local ore deposits and some excellent observations were submitted by those present. We wish this young institute every success in its useful work.

BY ITS SECRETARY, Mr. Charles D. Walcott, the Smithsonian Institution has invited the National Academy of Sciences and the American Association for the Advancement of Science, to make the Smithsonian Institution their headquarters. The invitation suggests that they deposit their archives and records in rooms provided for the purpose. The secretaries of the two organizations have accepted the kind offer of the Smithsonian and these three national scientific societies will now be gathered under one roof, enabling the Smithsonian Institution to achieve the purpose of its founder, James Smithson, namely, "the increase and diffusion of knowledge among men."

LASSEN COUNTY has "a soap mine;" so says the *Chronicle*. Two prospectors found a deposit of soapstone, several feet thick, which "is thought to come from the decayed bones of fish." It is "also said to be antiseptic in character." This is an excellent sample of newspaper science. However, we rejoice, for now Lassen county can have a new motto: "While there is life there is soap." Possibly the altruistic population of Lassen will send a few carloads of its soap to wash the blot from off the escutcheon of San Francisco. We need soap, especially one that is "said to be antiseptic."

ON FRIDAY LAST while the tramway officials were trying to run one or two cars in San Francisco, by the help of an inadequate police force, the following incident occurred, so says the *Chronicle*. "On Oak street an old couple appeared in an open window and waved American flags as the crews passed. The cars stopped and the crew raised their hats. The man, who must have been 70 years of age, lifted his voice and

shouted: 'May God grant that this flag will ever protect you in your desire to sell your labor at any wage you choose to accept.' The crowd cheered and the cars started on." Those cheers will echo in the hearts of many who read the account. For 130 years that flag has stood for equality of opportunity and essential manhood.

GOLD MINING IN ENGLAND has been something of an iridescent dream and now our London correspondent tells us of a big lode of gold-bearing conglomerate found in the Forest of Dean. The speeches made to the shareholders remind us of similar orations that tickled the fancy of the inexperienced in the days of Rameses. Apparently a deposit of conglomerate containing gold must necessarily pay if there is enough of it, but there is the corollary that if the stuff is too low-grade the larger your scheme of operations the bigger your loss. Ore that does not pay is no better than beach sand. There is gold in sea-water and there is heat in moonlight. The assays given by the Chastan Syndicate do not look enticing, for it is a brutal fact that the recovery in the mill is usually less than the assay.

Gold Mining in Egypt.

UM RUS, the ancient gold mine in Egypt that was re-opened by an English company, has been closed down, and the company has gone into liquidation. The first ore produced averaged an ounce of gold, but deeper development has proved disappointing. There are 6,000 tons of ore in the mine that will average 12½ dwt. per ton, but this cannot be extracted at a profit. Such a result gives point to an exclamatory paragraph in a letter received by us this week from Egypt, from a mining engineer, who says: "Why is it that people think that this desert country with its crumpled hills and sandy plains, that has been searched for gold for several thousand years, by prospectors as keen as any that ever lived, should be an untouched Golconda?" Well, those who thought so, know better now, for gold mining in Egypt is a dead industry. It owed its renaissance to fortuitous circumstances, among which the connection of an honored firm of mining engineers and the interest of a prominent South African capitalist were the most notable. If the modern speculator has not been enriched, at least he has learned something of archeology. On one mine two inscriptions have been found in Arabic dating back 819 years. The country was prospected by the early Egyptians and Phenicians, later by the Romans, and then by several generations of Arabs. The original grinding machine, back of the *arrastre* and Chilean mill, was probably invented in Egypt and carried by the Romans into Spain, whence Hannibal got the gold needed for his campaigns; by the Spaniards this forerunner of the *arrastre* was taken to Mexico and South America. Apparently the primitive metallurgy of the ancient world sufficed to extract most of the precious metal, for the best talent has failed to find much of it during the recent Egyptian boon. They have an Inspector General of Mines in Egypt now, and that sounds worthy of the Pharaohs, but despite this impressive officer and the expenditure of several million dollars, there is no profitable gold mine in Egypt today. The Nile Valley Company had a pyrotechnic career on the London stock market, and it is now trying to find ore. Um Rus, after being "shut down for 2,000 years," was re-opened by a company that was subsequently re-constructed, and is now to be liquidated. It costs $35 per ton to transport material 200 miles, labor is inadequate, water is scanty, and gold is scarce. That is why gold mining does not pay in Egypt.

Rampant Individualism.

INDUSTRIAL CONDITIONS in the mining regions of the West are likely to suffer from the action of the operators at Goldfield and Tonopah, particularly the former. At the present time miners get $5 per shift at Goldfield and $4 at Tonopah. When working in shafts, wages are 50 cents more, so that $5.50 is paid to men engaged in sinking. Workmen on surface get $4.50 at Goldfield and $4 at Tonopah. As the two towns are about thirty miles apart, the result is to draw miners to Goldfield from Tonopah, and to Nevada in general from the other mining States. Every man is entitled to the wages he can get and an operator is entitled to make his own terms with his men. But there are limits to this freedom of contract, for behind the individual is the community that gives him legal protection and the opportunity to perform his work. To that community the individual is always beholden. In the case cited, we believe that the anxiety to extract rich ore at any cost, in order to support a weak stock-market, is likely to subvert industrial conditions and to injure the community as a whole. Of course, we are aware that there is an alleged humorous side to this subject, for it is said that the miners drop most of their high wages in the gambling establishments controlled by several of the mine-owners, but as a matter of fact only one or two of the operators have such facilities and the chief reason for the exorbitant rate is the haste to extract ore of unusual richness. Everything is subordinated to this. The lessee wants to extract the maximum amount of ore during the term of his lease, the lessor has his eye on a top-heavy stockmarket and is anxious to see things booming. What does it matter if he pays extraordinary wages and creates labor unrest; what does it matter if miners steal the rich ore and the morality of the community is debauched thereby; the main thing is to get out the ore and make big shipments. The mines will be gutted, the ore will enrich 'undesirable citizens,' mining as an industry will be discredited, but the individual thrives. It is individualism in a destructive form, and to that extent it typifies the tendencies of modern life, where the civic spirit is dead and predatory selfishness is rampant.

It is the same story in San Francisco. The metal workers have struck because they have failed to force the ironworks to pay them wages and to allow them hours that are impossible if the employers are to make any profit in their business. The latter have offered to grant

even the terms demanded whenever 50 per cent of the other ironworks in the East make similar concessions, it being claimed—justly, we think—that to grant higher wages and shorter hours than their competitors in other cities, would simply make it impossible to operate at a profit. The men have struck, work has ceased, and the reconstruction of the ruined City is held in abeyance. There is no thought of the welfare of the community, there is no sympathy for the men who are doing their best to rehabilitate the City, there is nothing but unenlightened selfishness, born in greed and fostered by ignorance. Of the carmen's strike and the incipient anarchy arising from it, we shall speak later on. We are inclined to question, as Truthful James did on a certain historic occasion,

"Is our civilization a failure?
Or is the Caucasian played out?"

The Mining Graduate.

THIS is the season when young men are graduated from the schools of mines and start on their career. They have had lectures enough to last for several years, and they have been loaded with advice more than they can comfortably assimilate, therefore we shall not burden them further with similar injunctions. On the contrary we address ourselves to those who are a bit ahead of these new graduates, that is, to the older men of the profession to whom may come the opportunity to do a kindness or to give a helping hand. Most of us were inexperienced once, we started with the freshness of the graduate who has a world to conquer and if we look back a few years we remember that our verdancy was more vivid and our inexperience more helpless than even the youngest of the fellows that may come to us today for a suggestion, a bit of advice, or a job! The graduates have had their baccalaureate sermons, why not give one to the post-graduates, to the old campaigners in the field? We venture to give one, counting on a favorable hearing because of the professional spirit that is almost the only fine thing left in a day of low ideals and corrupt politics. To these post-graduates in the school of experience in which the learning is never finished until life itself brings the lesson to an end, to them we proffer the request to encourage the young fellows. Even if you cannot give them employment, give them encouragement of the kind that would have heartened you when you were starting out. There are plenty of men to tell them how difficult it is to get on, and how rough is the path that leads to an uncertain sort of success; don't bother to reiterate this sort of thing, but give them a cheery word and a warm hand-clasp, tell them of some of the blunders that you made and the obstacles that you overcame. Let them know that although the work is not always in accord with the purpose of their education, and not necessarily in direct fulfilment of their ideals, it is worth doing, if for nothing else then as a preparation for an opportunity that may come. It is true we have heard of mine managers and smelter superintendents, themselves college graduates, who have announced that they wanted no university fledglings, but preferred those recruited more directly from the laboring class. For men that are such renegades to their own training, and so ungrateful to the ladder by which they have ascended, we have a cheerful contempt, for if a technical education does not make a young man more intelligent and useful, we have all made a basic blunder, and had better become hod-carriers. Fortunately such narrow-minded persons are scarce, and are rarely in authority for long, so we shall hope that our friends that graduate this year will escape an encounter with them. Most of the older professional men have learnt enough from their own blunders and successes to be aware how much they owe to a little help at the start, when each man depends upon the kindly consideration of others far more than upon any merit of his own. And whether you become the first man in your profession, or accumulate a million, you can at least win one thing worth having, and that is the gratitude of some young fellow whom you have assisted at the beginning of his career. You may have to assist several to get the gratitude of one, or you may be lucky and be remembered in the goodwill of each one that you aid; possibly, you may not be informed of the kindly feeling felt for you by any of them; in whatever way this intensely personal equation may work out, it is something to be balanced against eminence or wealth if one or two useful men can say ten or twenty years hence that they owe their first start to you, to your courtesy, to your encouragement, or to the work that you gave them the chance to perform. Some one helped you at the commencement of your career; pass it on.

IT WAS STATED in Associated Press despatches that the Supreme Court of the United States had granted an injunction to the State of Georgia against the Tennessee Copper Company and the Ducktown Sulphur & Copper Company restraining them from operating their smelters on the ground that they are a public and a private nuisance and a menace to public health. The fact, as we are informed by telegraph, is that the Supreme Court upheld the right of the State to demand protection for its forests. The Court, however, declined to issue any injunction at the present time, agreeing to give the Tennessee Copper Company reasonable time to complete the building now in progress and to demonstrate to the State of Georgia that the conditions in regard to fume can be so improved as not to cause any appreciable damage. On the failure to do this, the Court announces its willingness to issue an injunction, but not before October next. Before that time the sulphuric acid plant will be running and it is expected that the company will be enabled to make an entirely satisfactory arrangement with the State. This news is important, as it has a bearing on the agitation started against the San Bruno copper smelter, at South San Francisco. We regret the prejudice, based largely on ignorance of the real facts, that has prompted the opposition to this important industrial enterprise. We shall refer to the matter again; for the present it remains but to suggest that the protestants get unprejudiced technical advice and meet the officials of the smelter in a fair way.

Personal.

F. W. BAKER is in New York.

D. CHISHOLM, of Colorado Springs, is at New York.

F. L. RANSOME is ill with pneumonia at Washington.

J. M. CALLOW has returned to Salt Lake City from Denver.

NEWTON BOOTH KNOX was married at Yokohama on May 10.

FRED. FULLER, of New York City, is at Cananea, Mexico.

CHARLES BUTTERS sails from New York by the *Cedric* on May 17.

A. E. REYNOLDS has been on a visit to San Francisco, from Denver.

PHILIP ARGALL is going to London, sailing from New York on May 30.

REES C. VIDLER has returned to Georgetown, Colo., from London.

HERMAN WENDLER left Ures, in Mexico, on May 15, for a business trip in Europe.

W. G. MOSHER has returned from La Union, in Salvador, to his home at Kansas City.

THOS. D. MURPHY has been sampling mines in the Ameca district of Jalisco, Mexico.

ALFRED W. HARRISON, of Silverton, is the guest of his sister, Mrs. E. G. Stoiber, at Paris.

NORMAN DANVERS POWER arrived on the *Mongolia*, on his way from Australia to England.

FRANK H. PROBERT will be married at Washington on May 25, and will then proceed to Europe.

M. F. BARCLAY, who has been at Tonopah recently, on his way from London, is in San Francisco.

G. McM. ROSS and J. ALLEN REID have just returned to Stockton, Cal., from a geological trip through Nevada.

FRANK H. PROBERT will be married at Washington on May 25, and then he and his wife sail for Europe from New York.

T. H. OXNAM, general manager for the Consolidated Arizona Smelting Co. has gone to New York on important business.

ALEXANDER N. WINCHELL has been elected to fill the chair of petrography and mineralogy in the University of Wisconsin.

A. G. GORDON WILSON is in Colorado from Salt Lake City on business connected with the Kelly Filter Press Co., of which he is the vice-president.

C. G. PATTERSON, erecting engineer for Chas. Butters & Co., passed through San Francisco this week on his way to Mexico to superintend installation of the Butters filter.

M. E. MACDONALD has resigned as general manager of the Guanajuato Consolidated M. & M. Co.'s properties at Guanajuato, Mexico, and becomes consulting engineer for the same company, making his headquarters at its New York office in the Mills Bdg., 35 Wall St., but retaining an office for his private business at 40 Wall Street.

Obituary.

JOHN M. BELL, a former mining engineer and placer miner of Butte, Montana, died at Chalchihuites, in the State of Zacatecas, Mexico, on April 23, from blood-poisoning. He was connected with the mining department of the Chalchihuites Mining & Smelting Co., and while on a visit to one of the mines, his horse fell, causing a small wound on the knee, followed by blood-poisoning, which caused his death after seven weeks' illness. Mr. Bell was born at Teesdale, England, and came to the United States when about one year old. He served in the Civil War, and went to Montana soon afterward to conduct placer mining operations. He was elected to the House of Representatives in Deer Lodge county in 1880, and served for two years.

Mining Summary.

ARIZONA.

COCHISE COUNTY.

The Copper Queen smelter handled more ore during April than in any other month in the history of the plant. Reports state that 106,000 tons of ore were treated, the production being about 9,500,000 lb. of copper. All the furnaces were in operation during the month.——At the Calumet & Arizona smelter, the production was about equal to that for March, the output being 4,000,000 lb., which includes ore from the Superior & Pittsburg and the Calumet & Arizona mines.

Bids will soon be asked for to drive the drift from the Higgins shaft to the body of ore that was recently encountered in the Wolverine by the diamond-drill, about 450 ft. from the shaft. An old drift runs from the Higgins claim toward the Warren claim of the Wolverine, and contracts for the extension of this drift will be let in sections of 500 ft. each.——In the Paradise district of the Chiricahua Mtn., mining activity continues. At the Savage the long tramway to the smelter is nearly complete. Shaft No. 1 is down 145 ft. and stoping is being carried on, the ore averaging about 5% copper. Shaft No. 2 is on another vein, running parallel with the first.—— Morrow & Chamberlain are shipping to the smelter from their property near Paradise.

Map of Arizona.

PINAL COUNTY.

In the Kelvin district, the Big Lead M. & S. Co. is running its 50-ton concentrator, making a good grade of copper concentrate.——The Kelvin Reduction Co.'s mill, with a capacity of 60 tons per day, has started and is treating ore produced by the Big Lead Co.——The Calumet is making regular shipments.——The Arizona Hercules Copper M. Co. is increasing its force of men.

CALIFORNIA.

BUTTE COUNTY.

The executive committee of the Mine Owners' Association has decided to secure the services of the Pennsylvania dredge, to throw up a barrier of tailing at Gold Run, a point on the river below Oroville. The inner side of the stone barrier will be covered with a layer of earth, and then the water will be held until all the sand settles. The committee will visit each dredge and arrange with the operators to throw up a portion of the barrier on the ground being worked, so that there will be one long, continuous restraining wall all along the river, in accordance with the agreement recently made with the committee of the Anti-Debris Association.

ELDORADO COUNTY.

All the mines at Angels Camp are closed on account of the strike of the miners.—— Henry Koppikus has bonded the Clipper mine in the Georgetown district to New York parties.—— The work of re-timbering the lower tunnel at the Standard mine is progressing rapidly. The mill will soon start.—— At Georgia Slide, the Beattie, Pacific, and Blue Rock are working with full crews.—— A cross-cut is being run to the vein, below the old workings, in the Neptune mine, adjoining the Trench mine on the south.—— Some rich strikes are reported in the Volcanoville district.

NEVADA COUNTY.

The machinery at the South Home mine has been overhauled, the compressors repaired, and a new 1,200-ft. cable put on the hoisting-drum, and everything is in readiness to begin work. This work has been done by the Champion Mining Co., which now owns the property.

The Grass Valley miners' union has sent a request to the Mine Operators' Association, asking for an increase of 50c. per day for underground men. The operators have not considered the question yet, and no hint has been given as to what their action will be. The miners claim that many of the best men are leaving the district, to go where wages are higher.——Lessees have begun work on the Chicago mine, a few miles southeast of Nevada City. This mine has yielded some rich pockets, and Jauch & Co. will run the tunnel ahead, at the same time stoping on the lode already opened.——A crew of men is driving both ways on the vein, at the 160-ft. point in the Niagara shaft, at Kentucky Ridge. The Cornish pump is handling the water satisfactorily, and a new hoist will soon be installed.——Colorado parties have been inspecting the old Hudson mine, a couple of miles west of the Niagara.——A tunnel is in 100 ft. on the vein of the Reynolds mine, below the Newton Ridge.——There is quite a boom in quartz mining in the French Corral district, which has always been a hydraulic camp.——Some good copper indications have been found in the tunnel on the A. Y. Brown ranch.——Sinking has been resumed at the Iron Mountain property.——A rich strike is reported, in the Inkmarque mine, near the North Star. The mine is owned by Louis Rosenthal, and Abe Brockington is in charge.

SHASTA COUNTY.

The Mammoth Copper Co.'s smelter will close for two weeks during the middle of the month, in order that extensive repairs may be made. All work outside the smelter will be continued as usual.——The Mt. Shasta Mines Co.'s property was sold under a trust deed, to the bondholders, for $50,000. Four years ago the company was heavily in debt and issued bonds, secured by trust deed given by D. P. Phelps and McKenzie Cleland. The company defaulted on the interest on the bonds and the property was sold, the transfer involving the Mt. Shasta, Lucky Boy, and Monitor claims.——The raise at the Gold Leaf mine near Shasta has holed through to the surface a distance of 130 feet.

TUOLUMNE COUNTY.

A number of local capitalists and mining men have recently purchased a valuable gold mine situated in the rich mining district, near Columbia. A corporation has been formed to take over the mine, and work on an extensive scale will be begun at once. Thomas C. Heide, who owns an interest in the mine, will be superintendent of operations at the mine. No difficulty has been experienced in procuring the money necessary to take up an option to purchase the property. This result has been the more readily effected by reason of the fact that the mine is largely developed, and machinery is in place on the ground. An abundance of ore assaying as high as $100 per ton is in sight, and an abundance of power at hand renders the cost of operation small. The principal claim owned by the company is the Mountain Boy, and the corporation has adopted the name of this claim, being called the Mountain Boy Mining Co. The company also owns two adjoining

claims. The principal place of business of the corporation is at Berkeley.

COLORADO.

CLEAR CREEK COUNTY.

Engineers have been examining the old Dunkirk property, with a view to purchase. Several carloads of ore from the dump were shipped to the Newton mill at Idaho Springs for a mill-run test, and it is believed that the dump can be milled at a profit. The Dunkirk is an extension of the Dives-Pelican lode.——The Central Colorado company has been reorganized, and the tunnel will be driven farther into Leavenworth Mtn.——Air-drills have been installed at the Mammoth property, in Brown gulch, which is being operated under lease and bond by J. M. Shaller and D. J. Williams.——The Smuggler mine is showing up well with development, and concentrating ore is shipped to the Terrible mill, which makes a lead and zinc concentrate.——Lessees on the Phillips lode are shipping concentrating ore to Idaho Springs.—— C. H. Dyer has leased the Stevens mine and mill, belonging to the Waldorf M. & M. Co., in the West Argentine district. There is much ore on the dump which can be milled at a good profit if some way can be found of running the mill without polluting the water supply of the town.

HINSDALE COUNTY.

Reports from Denver state that Bardwell, Mendenhall & Co. have sold the Highland Chief group on Sheep Mtn. This is considered one of the best lead prospects on upper Henson creek.

SUMMIT COUNTY.

(Special Correspondence).—The Ten Mile district is active and the Kokomo and Frisco districts will be heard from this year.

P. P. Edward, who is operating the Kitty Innes mine, has made a new strike in the lowest workings. A cross-cut tunnel was driven into the hill about 150 ft. deeper than where the previous strike was made, which produced good ore. The tunnel is now in to the vein and some good-grade silver-lead ore is being taken out.——The Mary Verna property adjoins the Kitty Innes on the north and has been developed by a cross-cut tunnel. Operations are to be resumed by the company under the superintendency of H. T. McAlister.——The King Solomon property lies north of the Mary Verna and the main tunnel is in 1,350 ft., having cut several veins. The management is preparing foundations for heavier machinery, the present compressor-plant having proved inadequate for the work.——It is reported that the North American property will resume operations in its main tunnel. This tunnel is 1,720 ft. long and cuts the veins at great depth.——The Excelsior property is being worked under contract. Ed. Flaherty is in charge and is running drifts east and west from the main shaft. Other drifts are being run from the 100-ft. level to open a four-foot vein of good-grade ore, ready for stoping. ——Andrew Westlund, who owns the Gold King property on Chief Mtn., has run a tunnel in 100 ft. on the vein, which carries a six-inch streak of auriferous iron ore with a smaller streak of lead ore. This property looks well for a prospect.——The operations in the main tunnel of the Square Deal company have been carried on without a stop all winter. The breast of the main tunnel is now 460 ft. from the portal and is in a mica-schist formation. Several veins have been intersected by the tunnel in its course but the objective point is yet ahead. Ed. Huter is superintendent.——The Victoria, an old-time producer on Royal Mtn., is to be started up again. A new company has been formed to operate the property, with A. E. Clarke as president.——In Heckman's property, adjoining the Victoria on Royal Mtn., a vein has been struck in the main tunnel 465 ft. from the portal.

The Colorado Dredging Co. is about to construct two new dredge boats, for work on the Blue and Swan rivers. They are of the Bucyrus type and will cost $105,000 each. Mr. Tuttle is superintendent for the company and states that they hope to have them finished in time for a short run before the season closes.——The Reliance Dredging Co.'s dredge boat will start up in a few days. This company has now assumed possession of the old Gold Pan plant as well as the shops and light and power-plant of the Colorado Con. Electric Co.——The Summit Banner Placer Co. will resume operations as soon as the snow has melted sufficiently to give the necessary water supply. This property paid dividends last year under the management of C. L. Kingsbury.

The Buffalo Placer Co.'s property at Dillon will be exploited this year under the supervision of L. Kingsbury.

Breckenridge, May 4.

IDAHO.

IDAHO COUNTY.

(Special Correspondence).—The work done on the Buster mine since it was taken under bond by Fred. W. Bradley and associates, of San Francisco, surpasses anything of the kind ever done in the central Idaho district, when the number of men working in the mine is considered. Since last September a depth of 300 ft. has been reached; a 100-ft. raise has been run; a 20-ft. sump has been formed at the lower level, and 100-ft. drifts run in both directions. A station has been formed 300 ft. from the mouth of the lower tunnel, large enough to accommodate the hoisting-engine, and the drift in the lower tunnel has been pushed 100 ft. farther. Much surface and placer work has also been done. The force has recently been increased to 27 men, and by the time the bond expires on July 1, it is confidently expected that the showing will be good.

Lewiston, May 10.

NEZ PERCE COUNTY.

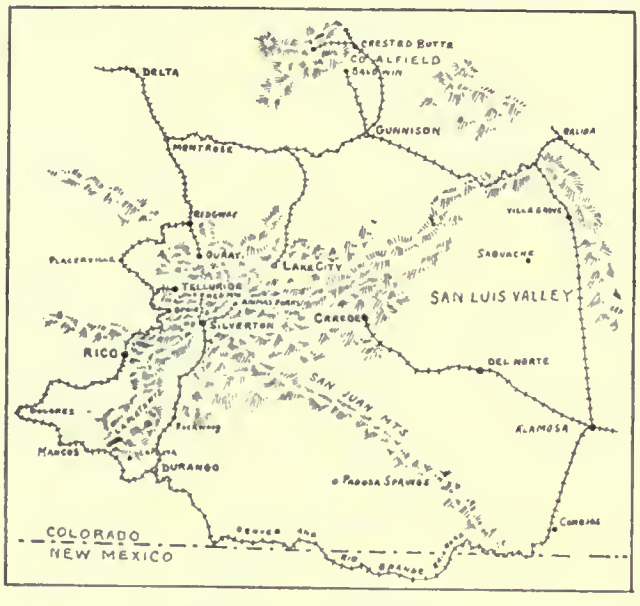
(Special Correspondence).—After several years of work, developing the Copper King mines on the Jacques spur of the Northern Pacific railroad, near the town of Winchester, John King, the owner of the properties, stated that he has made a good strike, some of the ore assaying $47 per ton.

Lewiston, May 10.

SHOSHONE COUNTY.

(Special Correspondence).—A deal was closed in Wallace, recently, when A. W. Woodworth, B. M. Francis, and G. J. Doherty of Missoula, purchased from Mrs. John Thomas a group of four mining claims near the Black Cloud mine on Nine Mile creek. The property is known as the North Star group. A 35-ft. drift on the vein encountered galena ore which averaged more than four ounces of silver per ton, and 44% lead. A company with a capital stock of $1,250,000 will be incorporated to develop the mine. Surveyors are now at work on a tunnel-site from which a 500-ft. cross-cut will be run.——Mining men from the Coeur d'Alene report that the strike recently made in the shaft of the Monitor mine is of great importance. They say the ore and vein-matter encountered at a depth of 389 ft. in the shaft continues at 410 ft. As first encountered, it had a width of 18 to 20 in., to which the management did not attach much importance further than recognizing it as a well-defined stringer lying parallel to the vein. This stringer has widened as depth is attained and others are coming in, all of which carry ore. The shaft is now at a depth of 410 ft. and is from 30 to 40 ft. into the foot-wall. The width of the mineralization at this depth is shown by the vein-matter and the ore which occurs so far from the main fissure.——Papers have been signed, giving to Frank Graves of Spokane a short-time option on 430,000 shares of the capital stock of the Bell Mining Co. at $1 per share. This gives Mr. Graves an option on control of the company, for the capitalization is only 500,000 shares of a par value of $1 per share. Finch and Campbell of Spokane and E. H. Moffitt of Wallace and their associates owned most of the stock on which the option was given. The Bell mine is considered one of the most promising of the non-producing properties in the Coeur d'Alene. It is west of the Morning mine, and south of the Frisco. The group comprises seven patented claims and two fractions, on which from $30,000 to $40,000 has been spent in development work. At one time much ore was shipped from the property, more than $100,000 worth of rich silver-lead ore having been taken practically from the surface.——Greenough Brothers who have an option on the Snowshoe mine, which adjoins the

Snowstorm on the east, are taking up the stock. The Snowshoe mine is capitalized for 1,000,000 shares and the option covers approximately 75% of this amount. The option was acquired some time ago, the majority of the stock being bonded for 17½c. per share. The No. 3 workings in the Snowstorm are being driven toward the Snowshoe, and it is evident that the orebody extends into the Snowshoe ground. When this reaches the Snowshoe it will give a depth of approximately 1,500 ft. John Mocine, acting manager of the Greenough properties in the Coeur d'Alene, says the orebody in the drift, that is being extended toward the Snowshoe, is showing up in such excellent shape that it was decided to take up the stock although the option is not due.——Electric drills will be used in the development of the West Hecla group at Burke. The machinery has been ordered. The power will be furnished by the Washington Water Power Co., a line being run from the station at the Hecla mine. This property was recently taken over by a Spokane corporation. A crew is being worked under the direction of McCallum, formerly superintendent of the Standard.——Carbonate ore has been encountered in the drift on the vein on the North Bunker Hill & Sullivan property adjoining that of the Bunker Hill & Sullivan mine on the north. The ore was encountered at a distance of 50 ft.



Map of Southwestern Colorado.

from the mouth of the tunnel. The drift will be continued a distance of about 400 ft. to get under a shaft on the surface in which some good ore was encountered, and the ore will be tapped at a depth of about 250 ft. The company owns five claims and a fraction.——Three adverse suits are about to be filed in the land office at Coeur d'Alene, at the instance of D. H. Brien, president of the Snowy Peak Mining Co., to prevent the granting of the patent applied for by the Tamarack & Chesapeake. The Monroe claim adjoins the Tamarack and it is claimed by the Snowy Peak company that the whole claim is over-lapped by the Silent Friend.——Work is progressing at the properties of the Hector Mining Co. at Wallace, and it is expected that the contract for 100 ft. of tunnel, which was recently let to Arthur F. George and Joseph Jellick of Wallace, will be completed within about 40 days. The tunnel has already been carried 100 ft. It is intended to carry this tunnel a total distance of 800 ft., when the ore that has been opened in two shallow tunnels higher up the mountain will be tapped at depth. Contracts are being let in sections of 100 ft. each.——Concentrates from the Black Cloud and California mines in the Nine Mile district of the Coeur d'Alene, near Wallace, owned and operated by the Pittsburg Lead Co., are reported to be the richest coming from the mills of the Coeur d'Alene at present. They are assaying 78% lead and 72 oz. silver. The Black Cloud and California mines are among the old producers of the district. A year ago the Pittsburg company obtained absolute control of them, but prior to that time the company had been operating them for a year. Since it first began work in the neighborhood of $200,000 has been expended in developing the mine and improving the mill. Fifty men are employed at the mine and mill, and the number will soon be increased.——The Hecla Mining Co., which owns the Hecla mine at Burke, has declared a dividend of 10c. per share, or $100,000. This brings the total for this year to $140,000, and makes the mine's total dividends to date $1,140,000. The regular monthly dividend is $20,000, or two cents per share, but extra dividends are paid every quarter. The Hecla company is incorporated for $250,000, divided into 1,000,000 shares of a par value of 25c. per share.——Directors of the Champion Copper Mining Co. decided to resume operations near Wallace, with three shifts of men. The four claims, which are in the Mullan copper belt, adjoin the Parl Copper and Springfield mines. The principal owners are: Adam O'Donnel, president, and John H. Wourms, treasurer.

Spokane, May 11.

INDIANA.

MORGAN COUNTY.

(Special Correspondence).—Much interest and activity is being shown this spring in the placer mining districts of Morgan county of this State.——The Magg & Roch machine, built by J. M. Neishart, of Pasadena, will commence operations within a week on Lamb's creek.—— Mr. Craver, of Chicago, is in the field, and expects to put his 500-yd. machine in operation soon. It is on Sycamore creek, at the junction of Gold creek.—— The Magnetic Mining Co. has its outfit nearly completed, and will be in operation on Sycamore creek, above Cottonwood Hollow, in a few weeks. —— The Gold Creek Mining Co., and Indiana Placer Mining Co., will commence work as soon as they can secure the services of a competent superintendent.—— There are many leases being secured in the territory, about eight thousand acres being under lease up to the present time, and gold placering will be done on an extensive scale.

Indianapolis, May 10.

MICHIGAN.

KEWEENAW COUNTY.

Navigation is now open at the copper country ports, and copper will be shipped by boat. None of the smelters have any surplus metal on hand, as every pound produced has been shipped by rail, with as little delay as possible. The arrival of the boats will preclude any possibility of a coal famine.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—Things are very lively here, and many of the mines are looking well.—— At the Bonnie Clare, development is progressing, some excellent ore has recently been extracted, and the sinking of the shaft steadily continues.—— A vein 18 in. wide has been discovered in the Gold Mtn. Eagle mine. The find was made in a shaft that was abandoned several years ago. A spur is being built to the mine from Montana station on the Tonopah & Bullfrog railroad, six miles distant.—— Some free-milling ore has been struck in the Nevada-Goldfield mine, at Gold Mtn.—— At the Wyman-Vick property, near Old Camp, the shaft is being sunk. George E. Wyman will superintend operations.—— Some ore has been encountered in the Centennial mine. Several men are employed, and indications are excellent.—— Local mining men are anxiously awaiting the coming of the Bishop Creek power-line, which will pass through this district. The coming of cheap power means that many of the mines now lying idle will be in operation.

Lida, May 12.

LYON COUNTY.

(Special Correspondence).—Copper has been struck in the Ramsey Comstock mine, in the shaft, within 20 ft. of the third level. The first time copper was encountered was in the second level. This time it is in the dike and the ore is not as rich as in the shoot along the seven-foot stringer in the centre of the dike. The incline shaft has been sunk on

a uniform pitch, and at the second level the wall bends to the west, as the vein flattens out and the shaft was continued in porphyry. Twenty feet before the third level was reached, the lode re-entered the shaft and shows copper, diminished, however, in value. In the shoot on the second level, the winze in the north drift has been sunk on the hanging wall, and the high-grade streak has bent west to the wall, where it is two feet wide and has changed to a hard sugary quartz. This ore is better in quality than when first encountered in the mouth of the drift and it is being sacked for shipment. When the third level is finished, the cross-cut extended across the dike, and the drifts opened up on either side in the high-grade shoot, the company will cease development except to continue the shaft to the 500-ft. level, and will begin work on a mill.

Ramsey, May 7.

NYE COUNTY.

(Special Correspondence).— Development at the West Extension is progressing, and a carload of ore from the west drift will be shipped to the smelter. The ore contains gold, silver, and copper. The suit of the West Extension Co. against the Apex M. & M. Co. has been decided in favor of the former company. The suit involved the title of the West Extension and Bullfrog Fraction properties.— The controversy between the Bullfrog of Nevada and the Diamond Bullfrog companies has been adjusted by the consolidation of the properties. An attempt was made to include the National Bank mine in the deal, but the latter company refused to join the merger.—— A 15-h.p. gasoline hoist has been installed in the winze on the fourth level of the Denver mine. The station is 20 by 50 ft., and at a vertical depth of 350 ft. The company will sink the shaft, cutting stations every 100 ft., and running drifts and crosscuts.—— The new hoisting plant on the Bullfrog Teddy is in operation, and the shaft is down 75 ft. Good ore has been encountered, and the management expects to strike the West Extension shoot. Both properties are controlled by the same company.—— Fred. Burnham and Leo Atcheson have disposed of their Big Sioux Warrior and Waldo claims at Lee to Boston capitalists.—— Several rich strikes are reported from the Mayflower, and the mine looks promisIng. The working force has been increased and some ore has been blocked out.—— A force of men is opening up ground at the Victor, and some good ore has been taken out.——It is reported that Walter Scott is about to dispose of his Death Valley mine to capitalists, including Louis Schloss, of San Francisco.

Rhyolite, May 10.

WHITE PINE COUNTY.

(Special Correspondence).—The Nevada Consolidated has been exploring a large area with churn-drills, and has encountered good copper ore in nearly every hole. The lack of experienced drillers is hinderlng the work of exploration.——Three shafts are being sunk on the holdings of the Ely Consolidated, and the mine systematically developed. The Brilliant shaft is down 120 ft. in sulphide ore. The American shaft is down 505 ft., and the Zack shaft has attained a depth of 350 ft. All the shafts are in good ore, and are equipped with gasoline hoists. The vein in the American contains silver, lead, and copper ore, running $30 per ton; 35 men are on the payroll.——The Steptoe Consolidated Co. is sinking a shaft on its claims. A four-foot body of ore was struck, the vein containing copper and lead.——Exploration work at the Ely Central is proving the existence of a body of fair-grade ore. In some of the holes, the vein is 125 ft. thick.——The Ely Hercules Co. has secured a bond on the Winston group and will immediately proceed to develop the property. Work will be at once started on the company's holdings at the Pass, 2½ miles from town.——Everything is in readiness for the installation of the machinery for the concentrator at the Giroux Consolidated property. Development work at the mine is rapidly progressing and large quantities of ore are ready for treatment.——A rich strike is reported from the Copper Jack claim at Mizpah, samples of the ore carrying gold, silver, and copper, and running several hundred dollars per ton. Two shafts, the Copper Jack and Jumbo, have been sunk on the claim. The Copper Jack is down 25 ft., and the Jumbo 45 ft. In the Copper Jack the lode is three feet wide.——Two shifts are sinking the shaft on the Tenderfoot claim and rapid progress is being made. Ore running $200 per ton is being extracted.——J. A. Fesley and Charles McFadden have commenced work on their El Moro property and will soon have a large force at work sinking a shaft.——Active development work has started on the Success shaft and the owners report the finding of some promising ore. Arthur Cordiner and J. Alpert control this claim.

Ely, May 10.

OREGON.

BAKER COUNTY.

Work will be rushed at the Golden Chariot, and a drift will soon be started from the shaft toward the vein.——The Crane Flat dredger will soon start work under the direction of George Telford.——The 20 stamps in W. E. King's Rainbow mine, in Mormon basin, have started dropping.—— Charles Guist has sold his half interest in the Wagner-Guist gold property in Mormon basin for $9,000.——A meeting of the shareholders of the Tourmagin Arm Mining Co., handling the California and the Oregon Development companies, was recently held in Chicago, and it is expected that more active work at the mines will result.—— The Bonanza mine and mill will be worked again under the management of Al. Geiser.—— C. M. McClaren will start work at the Adeline mine at once.—— There is a good deal of activity in the copper region east of Baker City. G. E. Alexander will superintend development of the mines belonging to W. H. Harris, in the Goose Creek district.—— Some good clean-ups are being made at the Pine Creek mines, owned and operated by the Merchants' Gold M. Co., of Baker City.

JACKSON COUNTY.

The coal mine on the Furry property, seven miles northwest of Ashland, has resumed operations. This mine is to be operated in connection with the Blue Ledge copper mine for Robert S. Towne, of New York. A new tunnel is being driven to drain the workings. It is in 100 ft. and will be driven 375 ft. farther.——Work on the coal property at Asbestos has been started. The vein is 14 ft. wide, with eight feet of good coal. The product will be hauled to Gold Hill.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The report at the annual meeting of the stockholders of the Pearl Consolidated Mining Co. shows that there is a large tonnage of ore exposed in the mines, but its average value is so low that a mill is needed on the ground to treat it. The company cannot raise enough money to build a mill and block out the ore to keep it running by assessing the stock up to the legal limit of five cents. Hence it was decided to lease the company's mines to H. L. Rodgers and give him an option to purchase them for $156,000, the royalty to apply on the purchase. The lease calls for a royalty of 10% of the gross assay value or all $8 ore or less that is milled, and an additional 50% on all ores having a value in excess of $8 per ton. The lessee must pay all taxes during the life of the lease, beginning with the year 1907 and pay interest on the mortgage against the company, and must begin work on the mine on or before August 27. The agreement on which the option to purchase was based, requires a mill to be completed not later than June 27, and the lease extends three years from that date. The ore shipped from the mine from March 1 to June 2, 1906, aggregated 1,641 tons, of a gross value of $10.33 per ton and netted over freight and treatment at smelter, $4.22 per ton. Ore shipped during the same period from the dump amounted to 241 tons, which netted $1.41 per ton.——F. R. McMillan has succeeded J. L. Harper in the management of the Belcher Mtn. railway, which is being altered and put in repair for continuous operation.——Work is being pushed on the adit at the Winnipeg mine, in the Belcher district. A sample of ore three feet wide, crossed by the adit, had a value of $97.70 per ton.——The Staight Mines Co. is following a streak of iron-sulphide ore from the lower adit on the

Anonymous group, which assays $8 per ton in gold. It was struck 375 ft. from the portal.——On the Columbia river, near Northside, in the northeastern part of Ferry county, machinery to sink 1,000 ft., consisting of a Sullivan air-compressor and duplex hoist, has been installed at the Sunset mine, which is showing up well.——On Iron creek, 40 miles southeast of Republic, on the south half of the Colville Indian reservation, an adit is in over 300 ft., and a three-foot vein has been encountered which carries copper, nickel, and silver.

Republic, May 10.

OKANOGAN COUNTY.

(Special Correspondence).—In the Meyers creek district, the Molson Gold Mining Co. has contracted for machinery for the Poland-China mine, consisting of a rock crusher, nine 1,200-lb. rapid-crushing quadruple-discharge stamp-mills, with automatic feeders; a No. 3 Merrall's improved roll-mill (Chilean principle), and large amalgamating plates; a 50-h.p. steam-engine and boiler, etc., to be supplied by the Merrall's Machinery Co., and to cost, installed, about $18,000. The company has a large tonnage of ore exposed in the mine, which is estimated to average about $20 per ton. The officers of this company are: D. W. Dart, president, and H. F. Beckery, general manager, both of Dayton, Ohio. M. A. Smalley, of Chesaw, Wash., is treasurer.

Republic, May 12.

MEXICO.

SINALOA.

Consul Louis Kaiser, replying to an inquiry from the United States in regard to the development and natural resources of the Mexican State of Sinaloa, writes from Mazatlan in part as follows: The State of Sinaloa is rich in mines and agriculture, and has millions of acres of

Part of Nevada.

splendid land for farming and stock raising, and is well suited for the culture of fibres of different kinds. These lands are nearly all undeveloped and bring from $1 to $10 per acre, according to quality and location. Investments of any kind should be made with the utmost caution, and only after a careful personal inspection.

The Southern Pacific Railroad Co. has secured from the Mexican Government a subvention of $750,000 gold, and the company has deposited $120,000 gold for the fulfillment of their part of the contract to build the Cananea, Yaqui River & Pacific railroad, which, when completed, will be 1,000 miles in length. Two sections of the road 200 miles in length are finished and are open for traffic from Empama, Sonora, south to Corral. From Corral the road will run to Valdervain and Buena Vista, and thence to Culiacan, the capital of Sinaloa. The third section extends from Mazatlan to Tepic, and the fourth section from Tepic to Guadalajara, the southern terminus. The rails for the road were bought in Spain, and most of the ties and sleepers in Japan. The contract for grading the entire length was awarded to a firm of Los Angeles, California.——The Kansas City, Mexico & Orient railroad is pushing its road from Topolobampo, a small port on the Gulf of California, and has about 150 miles of the line completed. The contemplated Durango & Mazatlan railroad, which will be a branch of the International line, and will be about 175 miles long, has finished its surveys, and it is now believed this extension will be built.——The climate on the west coast of Mexico for eight or nine months of the year is all one could desire. The rainy and hot season begins in July and ends the latter part of September.

SONORA.

At the Greene Consolidated property, development work includes two new shafts, shaft No. 12 and the new Prieta shaft. Shaft No. 12 is being sunk to the fifth level of the Veta Grande on the Oversight orebody, while the Prieta is down about 50 ft., near the north line of the Cananea-Bisbee.——Some ore is being taken out of the American mine, during development. New discoveries on the third level at the 170-ft. point, have demonstrated the presence of good ore. New ore-bins, with a capacity of 500 tons, will be built below the shaft-collar.——Some strikes of ore are reported in the Mina Mexicana of the Greene-Cananea company on the mesa about 10 miles south of Cananea.

NICARAGUA.

Consul E. W. Trimmer, of Cape Gracias á Dios, furnishes the following information in regard to the mining industry of Nicaragua: The mining industry in this district continues to show a steady improvement. Plants for the treatment of tailing by the cyanide process have been installed at a number of mines, and results have proved so satisfactory as to warrant a large increase in capacity. The output of gold bullion from this district now amounts to about 5,000 oz. monthly. The electric-power plant installed by one company has been in successful operation since February, 1906, and a new generator is now on the way and will be used to supply power to a group of mines. Transportation has been so much improved since the river steamer of the United States & Nicaragua Co. was put in commission that it is now possible to get machinery and supplies into the mines at a fair cost.——The ore-bearing limits of the district have not yet been ascertained, but the location within the past two years of many ore deposits at distances of 20 to 30 miles from the main properties warrants the belief in a fairly continuous ore-bearing zone along 50 miles or more of the foothill region, with a width of from 12 to 20 miles. Owing to the thick tropical growth, prospecting as it is known in the United States is impossible. Natives as guides and machete men are necessary. Several rich placer deposits have been discovered and worked out by crude methods, but in the opinion of mining men the present and future prosperity rests on the large bodies of medium-grade milling ore. The deposits thus far opened occur as replacements along fault lines and fissures, occurring largely in highly altered andesites and other eruptives. The surface soil and grass roots resting on and near the outcrop of ore-bodies have been found to contain gold at widely scattered points, and most of the mines have confined their operations to treating this surface soil in Huntington mills.

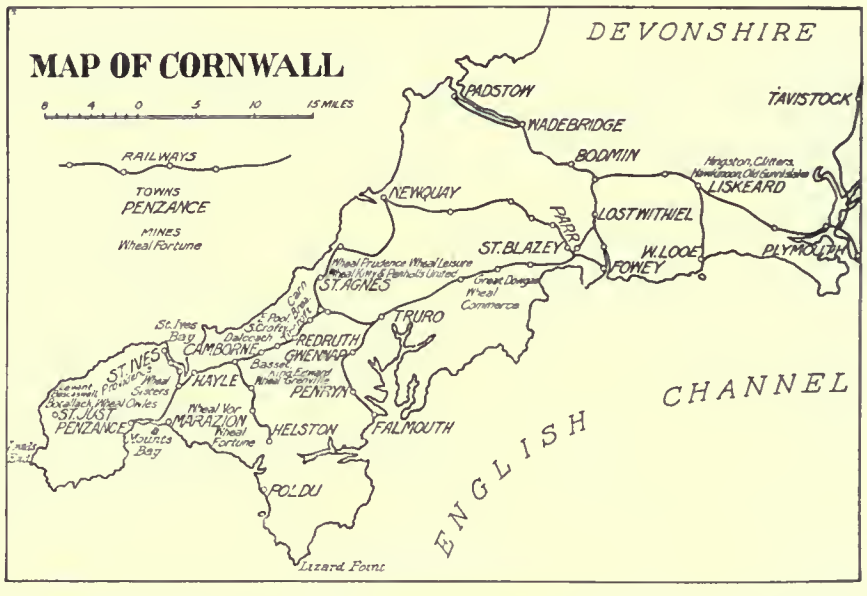
Rich shoots of oxidized ore have been found at all the mines near the surface, and below that point very little work has been done—in fact, there is not a hoist in the district. Unaltered sulphide ores occur in large quantities, carrying from $8 to $40 per ton in gold, in addition to sulphides of iron, zinc, silver, copper, and lead. The mines are at an altitude of 1,500 ft. above sea-level and distant some 250 miles by river, or 100 miles in an air-line, from the coast. For many reasons this is not considered a desirable country for a penniless miner, labor being performed cheaply by natives, but for a mining man who can command a few thousand dollars the district is considered by engineers on the ground to be a promising field. They also say that many known ore deposits exist which in the United States would be considered worth immediate development, the present operators selecting only those which are the most easily reached and favorably situated.

Special Correspondence.

London.

Banket in England.—The Chastan Syndicate.—Optimistic Speeches.—Labor in Cornwall.—Dolcoath Shaft.—Electrical and Cornish Pumps.

Lovers of beautiful scenery have had to put up with the operations of the Kent Coal Co., which, by the way, has not yet had the chance to mingle any of its product with the constituents of a London fog. What will now be said to the opening of a series of mines along a gold-bearing 'main reef' (with the roar of its stamp-batteries) alleged to have been discovered in the charming belt of country, lying between the rivers Severn and Wye, commonly known as the Forest of Dean? The directors of the Chastan Syndicate, which rejoices in an Admiral as chairman, have been the subjects of strong remonstrance from the press on account of the obscurity that veiled their doings while the stock was mounting to a substantial premium. Reasons for the directors' secrecy have now been made clear. At the general meeting this week the chairman told the stockholders that before the syndicate was formed the discoverer of the reef attached the utmost importance to the locality being kept a dead secret. The district presented great difficulties. It appears that every free miner in the Forest of Dean has the right to peg out a claim, but he is not obliged to develop this claim, but can let it stand over until it suits his convenience to do so. Secondly, there is great difficulty in finding out who really are the possessors of these claims, and, when you do, you find a great number of them, and they all have to be dealt with. The Company has succeeded in obtaining a freehold of 102 acres, and leases of 1,814 acres, with the entire command of the lode over 12 miles. The directors are asking for licenses to mine minerals of all sorts, and they are told there is good iron on the property. The actual net cost paid to the vendors of these properties, without commissions or legal charges, is £11,468. With regard to the explorations, an adit has been driven one-third of the necessary distance, and by the end of May the main body of ore will be reached. A report made by experts, specially chosen by some of the principal shareholders, showed low assay-values, but it substantiates three facts: In the first place, the experts say that the supply of conglomerate ore, similar to that of the Rand, is inexhaustible; in the second place, the whole length of outcrop shows gold; and in the third place, they say it can be worked at a small expense. Charles F. Kennedy, the managing director, addressing the meeting, remarked that the capital of the Syndicate was all subscribed privately, without any prospectus and without any publication whatever in the papers. It was only after spending some time on the property that he began to understand what a really stupendous proposition the Syndicate has. "You can see bold headlands sticking out as plainly as possible with conglomerate all over them. We have had it proved beyond any question of doubt that it is gold-bearing. There has not been a single sample taken from the property, to my knowledge, that does not show more than a trace of gold. The question is: Is it a payable proposition? If it is a payable proposition—even if the returns after paying expenses are very low, and it is a low-grade proposition—we have something that will be so huge in its returns, treated on a large scale, that there is not a gentleman in this room who can sum it up in figures."



In answer to a question, Mr. Kennedy said that of the manager's samples, which he took across six feet of reef, one went 3 dwt.; others went as high as 5 dwt. 5 gr. down to 16 gr. The average result of something like 17 samples was 3 dwt. 8 gr. The adverse experts say that the cost of working will be well under 8s. per ton. The Syndicate manager states that it will be about 8s. If, therefore, said Mr. Kennedy, they had a yield of 3 dwt. per ton, and 1 dwt. of it was profit, the result came to about £145,000 per annum with 600 head of stamps, and it would take many more lifetimes than those of everyone present put together to work the property out.

Turning to Cornwall, a local writer who speaks with authority states that "if Cornish miners co-operate with the capitalists in draining and proving the scores of mines that have long been idle, the time will come, the time of good profits and dividends, when the miner will command a larger wage than he will receive during the preparatory stages. And in the meantime the industry must be judged rather by the thousands who remain in it, than by the scores who after earning American or African wages and contracting the habit of spending freely, grumble at the rate of pay and again book their passages to the lands across the seas. Cornwall may not be an industrial paradise, but it has its points—as well as its pasties." The attitude of the new landlords regarding the pressing need for resuming the sinking of Williams shaft at Dolcoath continues the subject of eager discussion in the mining papers. A statement of Capt. Josiah Thomas is recalled, in which he said: "As to this new shaft, he wished that it was down instead of just being started, for it would undoubtedly effect, when completed, a vast saving in the working expenses of the mine." Further he added: "They might scarcely be prepared to hear this, but it took the men employed in the bottom of the mine from two to three hours to get down and to come to surface, so that they could not actually work much more than four or five hours per day. When the shaft was completed the men would be sent down to their work in two or three minutes." The efficiency of the Cornish pump, exemplified at Clitters United, as compared with electric pumping was referred

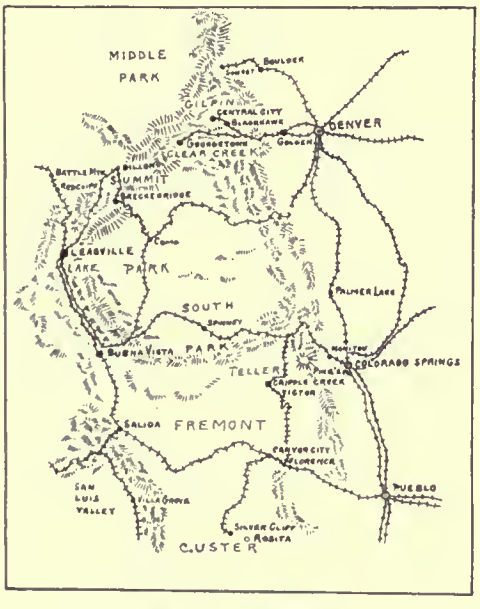
to at the meeting of stockholders recently. It appears that when they embarked upon the unwatering of the mine the plans, deposited in the Duchy, and which were supposed to be authentic, showed that it was a vertical and perfectly straight shaft, with no twists in it, and in installing the Cornish pump they allowed for this straight shaft, whereas in actual working it proved to be in the nature of a corkscrew shaft. By the time they had reached the 140-fathom level that pump had come to the end of its power, until they could stop the pump and increase the speed of it by altering the gear. The directors ultimately decided to put in an electric pump, which would take them down to the bottom of the mine, and which should hold the water while they were making the change with the Cornish pump. From the time the electric pump was completed down to the 140-fathom level it has been nothing but one constant source of anxiety. The contractors kept changing and altering the pump in points where it was defective, but there was never a long enough run to make the management feel safe enough to disconnect the Cornish pump and rely for five or six weeks at a stretch upon the electric pump.

Leadville, Colorado.

Diamond-Drilling.—Report of the Yak Tunnel Co.—Excellent Results.—Future Policy.—Sugar Loaf Mtn.—Strike in the Matchless.—Leasing on the Ibex.—An Old Smelter to Resume.

A report recently issued by W. W. Davis, manager of Yak Tunnel Co., contains much of interest to the public generally. There was completed last year about 6,500 ft. of drifts, winzes, and raises; the diamond-drilling, which was an important feature of the prospecting work, amounted to 10,069 ft. The number of drill-holes bored was 33 and of that number 12 disclosed ore. The mammoth power-plant at the portal of the adit was sold last year to the Leadville Light & Power Co., but is still affiliated with the Yak company. There was shipped through this adit, during the past year, 160,000 tons of ore and waste. "About one-half of the ore shipped from the company's properties netted less than $3 per ton, but it was necessary to remove it during the regular course of development work." The report refers to the policy of the company in the matter of extending the adit into new territory for the purpose of draining and mining. After reciting its extension to No. 4 shaft of the Little Johnny, 10,813 ft. from the portal of the adit, it is stated that the bore of the adit has been extended 750 ft. beyond shaft No. 1 to the Little Vinnie shaft. "This extension has been made with proper contracts for drainage from the Golden Eagle Mining Co., the owners of the Little Vinnie claim, with advantageous arrangements for the company with lessees, whereby said shaft will ultimately be connected with the adit." As to the immediate future, the policy of the Yak company will limit the actual development work on company account (except in the case of the Fortune group) to certain properties west of those of the Sentry company, which lie west of a point about 2,500 ft. beyond the new Little Vinnie shaft. While due encouragement will be given to the development of properties beyond the Sentry group, the Yak, as a company, will not expect to engage in the development and exploration thereof, further than to arrange for driving of the adit under a form of contract believed to be just and fair for all concerned. However, work will be continued at the various points along the line of the adit, which has been in progress for some time past. The income for the year 1906 amounted to $426,259, of which $320,000 was distributed in dividends. The total dividends paid from March 31, 1904, to December 31, 1906, amounts to $707,685. "The Yak company owns in fee simple 195 acres of mining ground" together with large acreages of surface territory "and it may be concluded," states Mr. Davis, "that without the most modern and best approved equipment for carrying on these operations economically, the successful conduct of our mining would have been impossible."

The recent strike in the Sunday mine on Breece hill has proved to be a most substantial discovery and along with the Chipawa it now takes its place in the ranks of productive veins of the first rank.——There is more activity in the vicinity of Sugar Loaf Mtn. this spring than at any time in the past decade. The Dinero company, the most important in that district, has a thoroughly modern power-plant in operation and the adit is being pushed forward at the rate of eight feet per day. ——At the new Monarch mine the manager reports the Cleveland shaft to have reached a depth of 600 ft. The bottom of the shaft is called the fourth level and a drift is being driven to cut the vein that has furnished 1,000 tons of high-grade ore per month for more than a year.



A Part of Colorado.

The recent strike of rich ore in the Matchless mine, again brings the Tabor property into prominence. It will be remembered that this property has practically laid idle for the past ten years, but a set of lessees have shipped several carloads of ore from the new strike and with no signs of giving out.——Timothy Kyle reports that after beating down the water in the Evelyn shaft in Big Evans gulch, he has found ore of an excellent grade, which the former operators reported when driven out by the heavy flow of water.

The Ibex mine, with its 150 sets of lessees and 450 miners, is shipping the usual quantity of over 400 tons daily. The ore coming from the Hanewald lease is as rich as any body of ore ever produced from the famous property.——It is reported that the Elgin smelting plant, on the north side of the city, will be blown in again during the early part of the coming summer. This plant was built not many years ago, and is in good condition at the present time. The lack of smelting facilities in the district, especially for sulphide ores, has prompted Denver parties to seriously consider putting this plant again in operation.——A. F. Wuensch has installed an electric hoist and completed all surface improvements preparatory to sinking a shaft on the Delaware property, about 1,000 ft. southwest from the Crescentia. According to calculations based on the Crescentia, the first contact should be reached at 550 feet.

Toronto, Canada.

Shipments From Cobalt.— Exploratory Work in the Nipissing.— Mining in the Bed of Lakes.—Prospecting on Islands.—Manitou Lake District.

Shipments of Cobalt ore for the week ending May 4 amounted to 138 tons from the following mines: Coniagas 31, O'Brien 65, Silver Queen 22, Townsite 20 tons. Shipments have been light, the roads being almost impassable, and, for the same cause, the delivery of machinery has been much delayed. Owing to the activity of prospectors during the winter, and the large number of claims awaiting inspection, the staff of inspectors has been increased to eight. In addition to A. H. A. Robinson, who was engaged last year, the following have been appointed: A. G. Burrows, late provincial assayer, C. W. Murray, G. C. Mackenzie, G. R. McLaren, R. T. Irwin, E. Wade, and D. W. Houston. They enter upon their duties at once.

T. R. Drummond, the newly appointed superintendent of the Nipissing mine, has 250 men at work. The force will be increased to 600 as soon as the buildings for their accommodation are completed. In all nine shafts are being put down. A cross-cut run at the 110-ft. level from one of the new shafts has encountered vein No. 26 at this depth. The shaft on that vein is only down 60 ft., and the demonstration of its continued richness at a lower depth is regarded with much satisfaction. In the course of development work on vein No. 49, three cars of ore have been removed and are ready for shipment. Driving is being carried on at 110 feet. On vein No. 27 from the open-cut on which the larger proportion of the output has been taken, the shaft is down 60 ft., and 300 ft. of driving has been done in two directions. A cross-cut is being run for exploration purposes. The building for the sampling works is completed and the plant is being installed. Some ten cars of ore are ready for shipment.—— At the Ontario-Quebec mine two veins crossing at right angles have been found to yield good silver ore at the 50-ft. level. The larger vein showed 45 oz. silver per ton at 30 ft., increasing in richness at the lower depth.—— The Right of Way Mining Co. has engaged Joseph C. Houston, formerly of the O'Brien mine, as superintendent. Substantial buildings are being erected and the plant is expected to be in operation in June. Another shaft will be sunk opposite the Silver Queen, the vein of which runs into the Right of Way.—— The Kerr Lake Crown Reserve Co. has decided to lower the lake by eight feet, which will expose a considerable area of the bed. Native silver has been found 16 ft. below the surface of the water.——The Lumsden Mining Co. has 94 men at work on the Brady location, adjoining the Beaver and Temiskaming properties. As a result of 4,020 ft. of stripping, some 14 veins have been uncovered, showing native silver, in addition to cobalt, smaltite, and nickel.

The Temagami Silver Mining Co., which owns three islands in the Cross Lake arm of Lake Temagami and the adjoining bed of the lake, an aggregate area of 120 acres, has sunk a shaft 60 ft. on island A, where several veins have been uncovered. A depth of 60 ft. has been reached on a vein of galena, the ore carrying $86 silver and 350 lb. lead per ton. A copper vein with a surface width of 3 ft. was encountered in the shaft. R. E. Patterson, formerly superintendent for the Clergue Copper Co., is in charge.

At the Paymaster gold mine, in the Manitou Lake district, a new adit advancing on the 100-ft. level, has opened up a quantity of rich ore, the quartz being speckled with visible gold. Equally good ore has been found at the 200-ft. level.—— Trouble with the laborers has occurred at the Laurentian, in the same district, a number of recently engaged foreigners having become dissatisfied and quit work. The superintendent, R. B. Nickerson, is looking for men to fill their places.

Butte, Montana.

Productive Activity.— Several New Mines. —Belmont Shaft Re-timbered.—Improvements at the Reins.—New Machinery.—Davis-Daly Estates.—Railroad Rights to Mine.

Mining conditions generally are excellent in Butte and are constantly improving. Officials of the large companies say their mines have never produced so heavily and have never yielded a better quality of ore than they are now yielding. The smelting capacity of all smelters in the State is taxed to the utmost, and if smelting facilities were available the output of the Butte mines could readily be increased from one-third to one-half. Some of the new companies, organized within the past 12 and 15 months, are doing well. Several of them are already shipping ore regularly, among these being the Amazon-Butte, Butte Central & Boston Bullwhacker, and East Butte companies. There are other companies that are rapidly reaching the producing point, and may be counted on to yield considerable ore within the next six months. These latter include the Davis-Daly, Farrel, and Alliance. There are a score of others active in development and exploration work and many of them are expected to become productive within a year. Among them are the Butte & London, Butte & Bacorn, Butte-Milwaukee, North Butte Extension, Colusa-Leonard, Butte & Superior, Calumet & Butte, Ida-Montana, and Tuolumne. The stockholders of the Butte Copper Exploration Co. have not yet given up hope, though it may become necessary to sink deeper and to reorganize the company to raise more money with which to carry on the work. Among the other new companies that are doing some rapid sinking, but which do not expect to be in the producing class for several years, are the Butte & Ballaklava, the Pilot-Butte, the British Butte, South Butte Mining, and South Butte Copper.

The Reins Copper Co. has made some improvements at its mine, putting in a new air-compressor and an additional 200-h.p. boiler. The company is mining some ore on the 900 and 1,000-ft. levels and is carrying on development work at the same time. The ore mined is not large in quantity, but is high-grade, two cars recently shipped netting the company $5,500.——The Butte Copper Co. shaft on the Trifle claim has reached a depth of 620 ft. A station has been cut at the 600, where a pump has been installed. The company expects to reach the 1,000-ft. point early in September.

The Anaconda mine was closed for six days last week while repairs were being made to the engine, and during the suspension no ore was hoisted. The Anaconda Co. has decided to increase the shaft of the Belmont mine from two to three compartments, and re-timber the whole shaft from top to bottom. It is now about 950 ft. deep, and will be converted into the main working shaft. Connections have already been made with the shaft on the 1,600-ft. level of the Anaconda mine, and cross-cuts from various levels of the Anaconda and Never Sweat down to a depth of 2,400 ft. are headed toward the Belmont, which lies nearly a mile south of the Anaconda shaft. While the work of enlarging and re-timbering the Belmont is in progress, there will, of course, be no ore mined from that property.

Some erroneous statements relative to the Davis-Daly Co. published in the East may be misleading to people not familiar with actual conditions in Butte. The com-

pany unquestionably has some of the best mineral ground in the Butte district, but none of its properties are yet producing ore, and cannot be expected to be producing because the company began development work only a few months ago. Only one of its properties, the Silver King, has produced anything in recent years, and no attempt is being made to do any mining there, as the shaft is being sunk deeper. Sinking is also going on at the Mt. Moriah, Colorado, and Smokehouse, but no ore is being opened up. The long cross-cut from the Original mine has encountered a vein, but work had to be suspended temporarily on account of the heavy flow of water, and the value of the vein has not yet been determined. Driving also is going on at the 500-ft. level of the Smokehouse, but both east and west drifts have encountered a badly broken vein, and some exploration work has been found necessary. Therefore the published statements that the Davis-Daly Co. is producing ore or has opened rich deposits are erroneous. The company has several hundred acres of ground extending through the centre of the district and adjoining a dozen of the big Amalgamated mines.

An important question is being tried in one of several suits brought in the Federal Court at Butte by the South Butte Mining Co. against various property owners and small mining companies to determine its right to the mineral under the right-of-way of the Montana Central, or Great Northern, railway, the South Butte Co. being the organization that assumed title to the mineral claimed to be owned by the Great Northern. Not only the Great Northern, but other railroads, in many instances, secured easements without reservations of mineral rights by the grantors, and should the South Butte Mining Co. be successful in its fight, it would mean the loss of a vast amount of rich mineral ground in the Butte district. Many lawyers claim that a railroad company can not acquire title to mineral under a right-of-way deed, and on that theory the company is being opposed. Testimony is being taken before a master in chancery and the litigation will probably be long drawn out.

Chihuahua, Mexico.

General Activity in the Santa Barbara District.—The Tecolotes Mill. Veintiuno de Marzo.—Parral Power Plant.—The Adela Group.—Carvoid Mining Company.—Los Bronces.—The Santiago Mines.

The Cuadras mine, recently purchased from the American Smelters Securities Co. by the Marina Mines of Mexico, a London company, has been shipping steadily to the Torreon smelter. The shaft is down 515 ft. on the lode, which is 15 ft. wide at the 400 and 500-ft. levels. The average grade of ore, as given by Mr. Dodson, the manager, is 1,500 grams silver, six grams gold, 12½% lead, 5.79% copper. The lode is the southern extension of the Zaynas, which is one of the main veins in the San Francisco del Oro group of mines.

The Tecolotes mine, owned by the Guggenheims, in the Santa Barbara district, started the second unit of the 600-ton mill on the first of April, and work on the third unit is being pushed. The 2,500-h. p. Loomis-Pettibone suction gas-plant has been running for the last few months, and is giving satisfaction. The consumption of mixed coal, as given by one of the engineers, is 0.6 to 0.7 lb. per h.p.hr., or approximately 2½ lb. wood. The power-house, which contains nine 250-h.p. American Crosby engines, is almost completed and, after a month's test-run, has been taken over by the company. The engines are connected to General Electric Co. 200-k.w. 400-volt three-phase, 60-cycle generators. The mines are connected to the mill by a one-mile narrow-gauge railway, steam being used for the present, but it is the expectation to change to electric power later on. In the mines there are 800 metres of electric tramway. At the mill and power-plant they are erecting new houses for the accommodation of employees.

The Veintiuno de Marzo is now producing ore, and, as soon as the titles are secured, this property will begin shipping. It lies in the Jimenez district, four hours out of Rosario, the terminal of the Parral branch of the Mexican Central railroad. This property was denounced

Map of Mexico.

in March by Estaban Garcia of Parral, and consists of six pertenencias. The ore is copper containing some silver and gold, the average ore running 10% copper, 200 gm. silver, and 3½ gm. gold per ton. Work was begun on March 21, and good ore was uncovered at the start. It is the intention of the owner to push the work as fast as possible, and, as soon as the titles are secured, to begin the shipment of ore, which is now being stored on the patio.——The Parral Power & Reduction Co. has its power-plant completed, and is furnishing power to the mines, also to manufacturing indnstries in the city of Parral. The reduction mill at Parral, leased by this company, has been eqnipped with electric motors and will now be driven electrically. The company's new machine-shop is crowded with work, and an addition is likely.

Work on the Adela gronp in the Azules camp of the Santa Barbara district is being advanced. A tunnel is being driven to cut the veins, and is now 1,525 ft. long. At this distance, and at a depth of 1,300 ft., a blind vein has been cut. This vein is seven feet wide and assays as high as $22.32 in gold, with 32 oz. silver per ton. According to J. F. Hutchins, the manager, it is the intention to continue development work, and at the same time to drive the adit until the big Adela vein is cut, which it is estimated will be at 1,625 ft. from the month. The Adela group is owned by W. V. Pettit.——The Carvoid Mining Co. is developing its properties in the Parral district. This is called the Catarica group, and consists of four denouncements. The development consists of a 170-ft. vertical shaft, with a 130-ft. drift to the south at the 70-ft. level. The vein is from 4 to 14 ft. wide, giving a sulphide ore; that from the drift assays 9% lead, 17% zinc, 2½ gm. gold, and 6 oz. silver. In the bottom, the ore is better, and contains two per cent copper. It is the intention to continue sinking, and, with drifts at the different levels, fully to develop the property, and then to erect a small concentrating plant at the mine, unless in the meantime a custom concentrating plant has been erected in the district. W. E. Brock of Parral is the manager.

In the Santa Barbara district, the Los Bronces workings are down 300 ft., and at this level drifts and crosscuts are being advanced. This group of 25 pertenencias lies directly west of, and adjoins, the big mine of the San Francisco del Oro. The owners are the Messrs. McCausland, formerly of the Clarinas mine, which has but recently been sold. Ross McCausland states that it is their intention to develop these properties to the 500-ft. level, and only take out the ore necessary in working. The ore contains lead and silver, also gold and copper, and is similar in character to that of the San Francisco del Oro; it will apparently require the same treatment.

The Santiago group has recently been purchased by Nat P. Wilson, who has formed a company called the Santiago Mining Co., the principal stockholder being George I. Green of St. Joseph, Mo. This group comprises the San Nicolas and the Mina Grande, and lies in the central part of the Santa Barbara district, close to the Tecolotes. Extensive development work has been started under the personal management of Mr. Wilson, who is now sinking four shafts. Mr. Wilson says he will push work sufficiently to justify the erection of a milling plant, the first unit of which is expected to be built this fall. It is stated that there is a large amount of ore available from work done by the Spaniards in former years. The ore is valuable for lead and silver, but it contains also gold and copper. For immediate use a 200-h.p. steam-plant will be erected to operate the hoists, until electric power is brought into this part of the district.

Calumet, Michigan.

Navigation Opens.—General Activity Expected.—New Interests of Calumet & Hecla.

Spring has finally arrived in the Lake Superior copper district. The snow is melting rapidly and with a week more of such weather the snow will be gone, and the ground fit for exploration. Navigation has opened at copper country ports, and while the ice in Big Portage is too thick to permit boats to pass through Portage Entry, lake steamers are entering Portage Lake through the ship canal. Rail shipments of copper have ceased and copper is now being forwarded to the Eastern seaboard by the mixed lake-and-rail route, which means a saving of one-fifth of a cent per pound in freight charges.

From every indication the coming summer will be one of the most active in the history of the Lake Superior copper district. There will be exceptional activity in exploration, influenced, no doubt, by the high price of the metal. Work at the Centennial and Allouez mines, which recently passed into the control of the Calumet & Hecla Mining Co., is under the direction of that corporation's head officials in this district. Walter Fitch, who was connected with the Lake Superior iron industry for many years previous to his departure from Michigan for Salt Lake, where he took the position of general manager of the United States Mining Co., arrived in Calumet a short time ago to take the position of first assistant superintendent of the Calumet & Hecla interests.

At the Calumet & Hecla mines, great activity is manifested. The shafts on the Calumet conglomerate are furnishing upward of 5,000 tons of ore daily. The shafts on the Osceola amygdaloid also are furnishing a large tonnage, though not one-fifth that of conglomerate workings. Some ore is being shipped from the new shafts on the Kearsarge amygdaloid, but the production from that portion of the property has not yet reached large proportions.

At the Superior mine, in Section 15, which is controlled by the Calumet & Hecla, the openings are in ground of an encouraging nature. Sinking is being carried forward steadily and the drifts are being extended as rapidly as possible.

The La Salle company, a subsidiary company of the Calumet & Hecla, is developing its property as rapidly as the work can be accomplished. The Tecumseh, which forms part of the property, is shipping ore to the Calumet & Hecla stamp-mills at Lake Linden, having discontinued making shipments to the Franklin mill. The two shafts on the Caldwell portion of the La Salle are going down steadily, but have not yet reached much depth. The openings in the lower levels of the Tecumseh's No. 1 shaft are in good ore.——The Franklin Mining Co. is reopening the workings on the Pewabic amygdaloid that were closed down a few years ago, as the management believes they will return good profits on the present metal market. The workings on the conglomerate, at the Junior branch of the mine, are showing up well; No. 2 shaft in particular is encouraging, the lower openings being in good ground south of the shaft.——At the Rhode Island, a small force is employed in exploratory work, diamond-drill work being under way. The situation is not encouraging and the management is directing its efforts at present on the Kearsarge amygdaloid bed.

At the Tamarack mine there are still evidences of fire in No. 1 shaft, and no work is being done in that portion of the mine. The fire in the Tamarack started a year ago last January, originating in No. 2 shaft. No. 2 was idle for a year, but has been in commission the last few months. The fire appears to have drawn off into the

workings tributary to No. 1. As the latter has not been an important producer for many years, the fact that it is closed down does not mean that the Tamarack's production is suffering. No. 5 shaft is producing an excellent tonnage of high-grade ore and so is No. 3, which is the deepest shaft in the world.——The Quincy's production is now at the rate of approximately 21,000,000 lb. refined copper per annum. It is estimated that the company will earn sufficient money this year to pay its present dividends of $18 per share per annum, place $500,000 in the surplus, and care for considerable construction work, which has been deferred for the last two or three years.

It is expected that the Mohawk will sink another shaft this summer. It will be known as No. 6 and will be about 1,200 ft. south of No. 5. The latter is opening some excellent copper ground and is becoming a factor of importance in production. The Mohawk company is increasing its working force just as rapidly as men can be obtained and the production will be considerably larger before the end of the year. Improvements are being made at the stamp-mill.

The Ojibway Mining Co., a new concern organized several weeks ago by the Cole-Ryan syndicate, will begin exploratory work on its property in Keweenaw county in a short time. Capt. Thomas Hoatson of Calumet, mining director for the Keweenaw Copper Co., will be superintendent. The Ojibway lands were partially explored under the supervision of Dr. L. L. Hubbard of Houghton, former State geologist, before they were taken over by the present company. Some rich diamond-drill cores were obtained.

Each rectangle is a township, six miles square.

The Copper Region of Lake Superior.

Denver, Colorado.

The Cripple Creek Adit.—Mining on School Land.—Successful Leasing.—Oil Refinery at Boulder.—Activity Among Prospectors.

The formal inception of work on the new deep drainage adit at Cripple Creek is to be marked by considerable ceremony. On Saturday, May 18, Governor Buchtel will press the gold button starting the power-plant at the mouth of the adit. A large party of representative mining men from Denver, accompanied by a band, will arrive on a special train, and the mining men of Colorado Springs are expected to attend in a body, while delegations from Pueblo and other towns are also expected to be present. The ceremony will signify, in an appropriate way, the recognition of the high importance of the drainage project, and at the same time serve as an opportunity for pleasant social intercourse among the men whose business it is to "follow the pay-streak."

It is a most unusual thing for the public schools to appear in the role of mine-owner. This peculiar state of affairs is the result of the leasing operation on the Bull Hill school section, near Cameron. But as only four per cent royalty is exacted by the State, the lessees bid fair to profit much more by their operations than does the public school system. Incidentally, many of the lessees of the mines in the Cripple Creek district make substantial profits from their operations. A recent lease, just terminated, reports a net profit of $250,000 from eighteen months' operation. Many others have similarly done well. Whatever may be said of the leasing system from the standpoint of the management, it at least offers opportunity for men with a small amount of capital and a large amount of push and skill to reap the reward they deserve.

The erection of an oil refinery just east of Boulder is under way, which means a corresponding stimulus to the oil industry of that area. But the ebb and flow of industrial development present some curious phases to the enquiring mind. Not many years ago the lead smelters of the State possessed well-equipped desilverizing plants. Now they are, without exception, closed down. With the cessation of the buying of silver for coinage at the Western mints, the only market for that metal was in the East. Silver and gold locked up in base bullion can be shipped safely, at a low freight-rate. Separated and refined they must go by express at high cost. Labor is cheaper in the East, also. So the Colorado plants are now shippers of base bullion, and the desilverizing and refining plants stand silent and empty.

Like the "New Year reviving old Desires" the first breath of spring wakes the prospector to the call of the hills. The local papers of the State are filled with the buzz of the incipient egress of the prospector with his camp-kit and pack of grub upon the back of his patient burro. Routt county and the San Juan region manifest the greatest activity. Prospecting in the former is stimulated by the western progress of the Denver Northwestern & Pacific, or 'Moffat,' railroad. Most of the reports come from the Hahns Peak region, which, like the northward extension into Wyoming, has so far yielded little but expectations. Routt county is large and it is to be hoped that other parts of it will yield handsomely. The San Juan country is one of great promise still, and the prospector does well who throws in his lot there.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

REPEATED tests on carefully cleaned boiler plate, gave an average specific gravity of 7.932.

A PURE IRON, if it could be obtained, without carbon, phosphorus, manganese, silicon, or sulphur, would have a tensile strength of 34,750 lb. per sq. in., if tested in a ⅜-in. plate.

COMMON HIGH BRASS contains 61.5% copper and 38.5% zinc. Cartridge brass contains two parts of copper to one of zinc, and low brass is composed of 80% copper and 20% zinc.

THE exact efficiency of a particular turbine wheel must be found by experiment. It is considered hardly possible for the efficiency to equal 86%, and a turbine yielding 75 to 80% is extremely good.

THE stability of a dam against overturning about its lower edge is calculated by comparing its statical moment referred to that edge, with the resultant pressure of the water against its upper side.

IN THE Howe bridge truss, the diagonals are struts and the verticals are ties, while in the Warren girder, or triangular truss, there are no vertical struts, and the diagonals may transmit either tension or compression.

WIRE ROPE is as pliable as new hemp rope of the same strength, and the former will run over the same-sized sheaves and pulleys as the latter. But the greater the diameter of the sheaves, pulleys, or drums, the longer the wire rope will last.

A POUND of coal used to make steam for a fairly efficient refrigerating machine can produce an actual cooling effect equal to that produced by the melting of 16 to 46 lb. of ice, the amount varying with the conditions of working.

THE proponent of the inquiry concerning the location of claims by deputy mine surveyors is advised to employ a lawyer. He has been sued, according to his own statement, and he must have someone employed to look after his case. If not, he needs someone sadly. The MINING AND SCIENTIFIC PRESS has heretofore presented the question of the rights of deputy mine surveyors and the validity of locations made by them.

IN VENTILATING a mine or other underground passage, the resistance to be overcome is proportional to the extent of the frictional surface exposed; that is, to the product of the length of the gangway by its perimeter, to the density of the air in circulation, to the square of its average speed, and to a coefficient whose numerical value varies according to the nature of the sides of the gangway and the irregularities of its course.

GROUND MICA is used in some quantity, the coarser grades in mica bronzes and paints and also as an absorbent for explosives. Ground mica also forms an ingredient in some heavy lubricants. The finest ground mica or mica flour finds a considerable market with the manufacturers of high-grade wall papers, the lustre obtained by the use of the muscovite dust having the advantage of both permanency and brilliancy.

SCRAP MICA is utilized in the manufacture of a superior quality of boiler lagging, a mat of finely divided mica flakes furnishing a fireproof covering that has sufficient strength to be durable, not disintegrating like some other materials, and excelling asbestos and magnesia compounds as a non-conductor of heat. The superiority of the mica lagging appears to depend not only upon the low conductivity of the mineral itself, but especially upon the loose texture of the mica mat.

RAPIDLY as the population of the United States has increased, the lumber consumption has increased still more rapidly. In round numbers, and allowing for incomplete reports, the lumber cut in 1880 was 18 billion feet; in 1890, 24 billion feet, and in 1900, 35 billion feet. The increase in population from 1880 to 1900 was 52%, but in lumber cut, 94%. The United States is now using annually 400 board feet of lumber per capita, while the average for Europe is but 60 ft. per capita.

WHEN properly made, malleable cast iron should have a tensile strength of 42,000 to 48,000 lb. per sq. in., with an elongation of 5% in 2 in. Bars 1 in. square and on supports 12 in. apart should show a transverse strength of 2,500 to 3,500 lb., with a deflection of at least one-half inch. The resilience should be at least eight times that of cast iron. Malleable cast iron can be bent, twisted, and abused before giving way, thus making the material ideal for service where a fair tensile strength is required, but especially where often repeated shocks are the rule.

CALCIUM STEEL is a ceramic product formed by baking a paste made of finely pulverized feldspar, sand, and lime, mixed in certain proportions. The product has remarkable qualities, being a porcelain or earthenware of great hardness and durability. It resists corrosion by acids, is a poor conductor of heat and electricity, and has a specific gravity of only 3.3. Although hard, the material is tough, and can be machined like metals, being readily bored, cut, planed, or polished. One of the uses for which it is expected to prove valuable is for pipes and conduits for water, gas, and chemicals.

PURE COPPER cannot be cast in sand without difficulty; in fact, some deoxidizer is always used. For common copper castings from 2 to 5% zinc is generally added to get sound castings; but for electrical work this is useless. The only way to get good electrical castings is to melt pure electrolytic copper in a plumbago crucible under a thick layer of charcoal. When thoroughly melted, add 2% silicon copper and stir it in with a stick, and cast as soon as ready. Practical experience alone will show the correct temperature for casting copper in sand molds, and the proper temper of the sand. It must not be cast boiling, but a fairly high temperature is necessary.

THE process of making malleable cast iron may be briefly summarized as follows: The proper irons are melted in either the crucible, the air furnace, the open-hearth furnace, or the cupola. The metal when cast into the sand molds must chill white or not more than just a little mottled. After rolling off the sand from the hard castings they go into the annealing department, where they are packed in puddle scale, or other materials containing iron oxide, and here subjected to a period of red heat (1,250 to 1,350° F.), over 60 hours after reaching the proper temperature. They are then cooled gradually, rolled again to remove adhering scale, chipped or ground, straightened, and shipped.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Copper in Shasta County, California.

The Editor:

Sir—I have read with great interest the article of Mr. Donald F. Campbell on the geology of the Shasta copper belt in your issue of January 5. The efforts of Mr. Campbell to shed some light on the local geology must be highly appreciated by all engineers, as reliable information on the geology of that important district is much needed. In fact, as far as I know, the articles of Mr. J. S. Diller in bulletins No. 213 and 225 of the United States Geological Survey, and his text in the folio devoted to the Redding Quadrangle are the only sources of information at hand. Any reliable contribution to this subject must then be of immediate value to all mining engineers called to work in that district, and if in the following lines I may differ from some views of Mr. Campbell, I do this, not in a spirit of criticism, but in the hope that other men more fully acquainted with the local geology will give us the results of their observations.
